# **Description**

Draw bootstrap samples to be used for (fast-and-robust) bootstrap tests for mediation analysis. Note that this function is intended for use in simulation studies by experienced users.

### Usage

boot\_samples(n, R)

# Arguments

n an integer giving the number of observations in the original data set.

R an integer giving the number of bootstrap samples to be generated.

boot\_samples 5

# Value

An object of class "boot\_samples" with the following components:

indices an integer matrix in which each column contains the indices of the correspond-

ing bootstrap sample.

seed the state of the random number generator before the bootstrap samples were

drawn

BSG2014

Business simulation game data

### Description

The data were collected from 354 senior business administration students during a business simulation game at a Western European University.

The game was played for a total of 12 rounds (i.e., two separate games of 6 rounds) as part of the capstone strategy class. Students were randomly assigned to teams of four, and surveyed in three waves: prior to the first game, in between the two games, and after the second game (with different variables being surveyed in the different waves).

The 354 students formed 92 teams, and the responses of individual students were aggregated to the team level. Leaving out teams with less than 50 percent response rate yields n=89 teams. Only a small subset of the collected variables are included here.

#### Usage

data("BSG2014")

#### **Format**

A data frame with 89 observations on the following 13 variables.

ProcessConflict Based on Shah & Jehn (1993), the team members rated three items on the presence of conflict related to the process of working together, using a 5-point scale (1 = none, 5 = a lot). The individual responses were aggregated by taking the average across items and team members. Process conflict was measured in the second survey (between the two games).

SharedExperience As teams were randomly formed, no prior shared group experience is expected, and shared group experience and training is developed during the first game for the second game. Hence the team performance score on the first game is used as a proxy for the level of shared group experience and training. Those scores were computed through a mix of five objective performance measures: return on equity, earnings-per-share, stock price, credit rating, and image rating. The computation of the scores is handled by the simulation game software, and details can be found in Mathieu & Rapp (2009). The scores ranged from 57 to 111, and they were communicated to the teams only after the third survey.

TaskConflict Using the intra-group conflict scale of Jehn (1995), the team members rated four items on the presence of conflict regarding the work on a 5-point scale (1 = none, 5 = a lot). The individual responses were aggregated by taking the average across items and team members. Task conflict was measured in the second survey (between the two games).

TeamCommitment The team members indicated the extent to which they agree or disagree with four items on commitment to the team, which are based on Mowday, Steers & Porter (1979), using a 5-point scale (1 = strongly disagree, 5 = strongly agree). The individual responses were aggregated by taking the average across items and team members. Team commitment was measured in the third survey (after the second game).

BSG2014 7

TeamPerformance Following Hackman (1986), the team members indicated the extent to which they agree or disagree with four items on the team's functioning, using a 5-point scale (1 = strongly disagree, 5 = strongly agree). The individual responses were aggregated by taking the average across items and team members. Subjective team performance was measured in the third survey (after the second game).

- TMS Transactive memory systems (TMS) are defined as shared systems that people in relationships develop for encoding, storing, and retrieving information about different substantive domains. TMS was operationalized with Lewis' (2003) 15-item scale that measures the three sub-dimensions of TMS (specialization, credibility, and coordination). For each item, the team members responded on a 5-point scale (1 = strongly disagree, 5 = strongly agree). Following Lewis (2003), the three sub dimensions were aggregated to form the TMS construct. That is, the individual responses were aggregated by taking the average across all 15 items and team members. TMS was measured in the second survey (between the two games).
- ValueDiversity Using the short Schwartz's value survey (Lindeman & Verkasalo, 2005), the team members rated ten items on the importance of certain values (1 = not important, 10 = highly important). For each value item, the coefficient of variation of the individual responses across team members was computed, and the resulting coefficients of variation were averaged across the value items. Value diversity was measured in the first survey (before the first game).
- Procedural Justice Based on the intra-unit procedural justice climate scale of Li & Cropanzano (2009), the team members indicated the extent to which they agree or disagree with four items on a 5-point scale (1 = strongly disagree, 5 = strongly agree). The individual responses were aggregated by taking the average across items and team members. Procedural justice was measured in the third survey (after the second game).
- Interactional Justice Using the intra-unit interactional justice climate scale of Li & Cropanzano (2009), the team members indicated the extent to which they agree or disagree with four items on a 5-point scale (1 = strongly disagree, 5 = strongly agree). The individual responses were aggregated by taking the average across items and team members. Interactional justice was measured in the third survey (after the second game).
- SharedLeadership Following Carson, Tesluk & Marrone (2007), every team member assessed each of their peers on the question of 'To what degree does your team rely on this individual for leadership?' using a 5-point scale (1 = not at all, 5 = to a very large extent). The leadership ratings were aggregated by taking the sum and dividing it by the number of pairwise relationships among team members. Shared leadership was measured in the second survey (between the two games).
- AgeDiversity Following Harrison & Klein (2007), age diversity was operationalized by the coefficient of variation of the team members' ages.
- GenderDiversity Gender diversity was measured with Blau's index,  $1 \sum_j p_j^2$ , where  $p_j$  is the proportion of team members in the j-th category (Blau, 1977).
- TeamScore The team performance scores on the second game were computed at the end of the simulation through a mix of five objective performance measures: return on equity, earnings-pershare, stock price, credit rating, and image rating. The computation of the scores is handled by the simulation game software, and details can be found in Mathieu & Rapp (2009). The scores ranged from 49 to 110, and they were communicated to the teams only after the third survey.

 $ci_plot$ 

Dot plot with confidence intervals

### **Description**

Produce a dot plot with confidence intervals of selected effects from (robust) mediation analysis. In addition to confidence intervals, p-values of the selected effects can be plotted as well.

# Usage

```
ci_plot(object, ...)
## Default S3 method:
ci_plot(object, parm = c("direct", "indirect"), ...)
## S3 method for class 'boot_test_mediation'
ci_plot(
  object,
  parm = c("direct", "indirect"),
  type = c("boot", "data"),
  p_value = FALSE,
  digits = 4L,
## S3 method for class 'sobel_test_mediation'
ci_plot(
  object,
 parm = c("direct", "indirect"),
 level = 0.95,
 p_value = FALSE,
)
## S3 method for class 'list'
ci_plot(
  object,
  parm = c("direct", "indirect"),
  type = c("boot", "data"),
  level = 0.95,
 p_value = FALSE,
 digits = 4L,
)
```

10 ci\_plot

```
## S3 method for class 'setup_ci_plot'
ci_plot(object, ...)
```

### Arguments

object an object inheriting from class "test\_mediation" containing results from (ro-

bust) mediation analysis, or a list of such objects.

. . . additional arguments to be passed down.

parm an integer, character or logical vector specifying which effects to include in the

plot. In case of a character vector, possible values are "a", "b", "d" (only serial multiple mediator models), "total", "direct", and "indirect". The default

is to include the direct and the indirect effect(s).

type a character string specifying which point estimates and confidence intervals to

plot: those based on the bootstrap distribution ("boot"; the default), or those based on the original data ("data"). If "boot", the confidence intervals of effects other than the indirect effect(s) are computed using a normal approximation (i.e., assuming a normal distribution of the corresponding effect with the standard deviation computed from the bootstrap replicates). If "data", the confidence intervals of effects other than the indirect effect(s) are computed via statistical theory based on the original data (e.g., based on a t-distribution if the coefficients are estimated via regression). Note that this is only relevant for mediation analysis via a bootstrap test, where the confidence interval of the indirect effect is always computed via a percentile-based method due to the asymmetry

of its distribution.

p\_value a logical indicating whether to include dot plots of the p-values in addition to

those with confidence intervals. The default is FALSE.

digits an integer determining how many digits to compute for bootstrap p-values of

the indirect effects (see p\_value()). The default is to compute 4 digits after the

comma. This is only relevant if p\_value = TRUE.

level numeric; the confidence level of the confidence intervals from Sobel's test.

The default is to include 95% confidence intervals. Note that this is not used for bootstrap tests, as those require to specify the confidence level already in

test\_mediation().

#### Details

Methods first call setup\_ci\_plot() to extract all necessary information to produce the plot, then the "setup\_ci\_plot" method is called to produce the plot.

### Value

An object of class "ggplot".

12 coef.test\_mediation

# **Description**

Extract coefficients from models computed in (robust) mediation analysis.

# Usage

```
## S3 method for class 'test_mediation'
coef(object, parm = NULL, ...)

## S3 method for class 'boot_test_mediation'
coef(object, parm = NULL, type = c("boot", "data"), ...)

## S3 method for class 'fit_mediation'
coef(object, parm = NULL, ...)
```

# Arguments

object	an object inheriting from class "test_mediation" containing results from (robust) mediation analysis, or an object inheriting from class "fit_mediation" containing a (robust) mediation model fit.
parm	an integer, character or logical vector specifying the paths for which to extract coefficients, or NULL to extract all coefficients. In case of a character vector, possible values are "a", "b", "d" (only serial multiple mediator models), "total", "direct", and "indirect".
	additional arguments are currently ignored.
type	a character string specifying whether to extract the means of the bootstrap distribution ("boot"; the default), or the coefficient estimates based on the original data set ("data").

# Value

A numeric vector containing the requested coefficients.

```

confint.test\_mediation

Confidence intervals from (robust) mediation analysis

### **Description**

Extract or compute confidence intervals for effects in (robust) mediation analysis.

### Usage

```
## S3 method for class 'boot_test_mediation'
confint(object, parm = NULL, level = NULL, type = c("boot", "data"), ...)
## S3 method for class 'sobel_test_mediation'
confint(object, parm = NULL, level = 0.95, ...)
```

#### **Arguments**

object an object inheriting from class "test\_mediation" containing results from (ro-

bust) mediation analysis.

parm an integer, character or logical vector specifying the paths for which to extract

or compute confidence intervals, or NULL to extract or compute confidence intervals for all coefficients. In case of a character vector, possible values are "a", "b", "d" (only serial multiple mediator models), "total", "direct", and

"indirect".

level for the "boot\_test\_mediation" method, this is ignored and the confidence

level of the bootstrap confidence interval for the indirect effect is used. For the other methods, the confidence level of the confidence intervals to be computed.

The default is to compute 95% confidence intervals.

type a character string specifying how to compute the confidence interval of the ef-

fects other than the indirect effect(s). Possible values are "boot" (the default) to compute bootstrap confidence intervals using the normal approximation (i.e., to assume a normal distribution of the corresponding effect with the standard deviation computed from the bootstrap replicates), or "data" to compute confidence intervals via statistical theory based on the original data (e.g., based on a t-distribution if the coefficients are estimated via regression). Note that this is only relevant for mediation analysis via a bootstrap test, where the confidence interval of the indirect effect is always computed via a percentile-based method

due to the asymmetry of its distribution.

.. additional arguments are currently ignored.

14 cov\_control

### Value

A numeric matrix containing the requested confidence intervals.

cov\_control

Tuning parameters for Huber M-estimation of location and scatter

# **Description**

Obtain a list with tuning paramters for cov\_Huber().

# Usage

```
cov_control(prob = 0.95, max_iterations = 200, tol = 1e-07)
```

cov\_Huber 15

# **Arguments**

prob	numeric; probability for the quantile of the $\chi^2$ distribution to be used as cutoff point in the Huber weight function (defaults to 0.95).
max_iterations	an integer giving the maximum number of iterations in the iteratively reweighted algorithm.
tol	a small positive numeric value to be used to determine convergence of the iteratively reweighted algorithm.

### Value

A list with components corresponding to the arguments.

# Author(s)

Andreas Alfons

```

# **Examples**

cov\_Huber

Huber M-estimator of location and scatter

# Description

Compute a Huber M-estimator of location and scatter, which is reasonably robust for a small number of variables.

16 cov\_Huber

#### Usage

```
cov_Huber(x, control = cov_control(...), ...)
```

#### **Arguments**

x a numeric matrix or data frame.

control a list of tuning parameters as generated by cov\_control().

... additional arguments can be used to specify tuning parameters directly instead

of via control.

#### **Details**

An iterative reweighting algorithm is used to compute the Huber M-estimator. The Huber weight function thereby corresponds to a convex optimization problem, resulting in a unique solution.

#### Value

An object of class "cov\_Huber" with the following components:

center a numeric vector containing the location vector estimate.

cov a numeric matrix containing the scatter matrix estimate.

prob numeric; probability for the quantile of the  $\chi^2$  distribution used as cutoff point

in the Huber weight function.

weights a numeric vector containing the relative robustness weights for the observations.

tau numeric; correction for Fisher consistency under multivariate normal distribu-

tions.

converged a logical indicating whether the iterative reweighting algorithm converged.

iterations an integer giving the number of iterations required to obtain the solution.

x <- "ValueDiversity"
y <- "TeamCommitment"
m <- "TaskConflict"

# compute Huber M-estimator
cov_Huber(BSG2014[, c(x, y, m)])</pre>
```

cov\_ML

Maximum likelihood estimator of mean vector and covariance matrix

# **Description**

Compute the maximum likelihood estimator of the mean vector and the covariance matrix.

### Usage

```
cov_ML(x, ...)
```

### **Arguments**

x a numeric matrix or data frame.

... additional arguments are currently ignored.

### Value

An object of class "cov\_ML" with the following components:

center a numeric vector containing the mean vector estimate.

cov a numeric matrix containing the covariance matrix estimate.

n an integer giving the number of observations.

density\_plot

*Density plot of the indirect effect(s)* 

# Description

Produce a density plot of the indirect effect(s) from (robust) mediation analysis. In addition to the density, a vertical line representing the point estimate and a shaded area representing the confidence interval are drawn.

### Usage

```
density_plot(object, ...)
## Default S3 method:
density_plot(object, ...)
## S3 method for class 'sobel_test_mediation'
density_plot(object, grid = NULL, level = 0.95, ...)
## S3 method for class 'list'
density_plot(object, grid = NULL, level = 0.95, ...)
## S3 method for class 'setup_density_plot'
density_plot(object, ...)
```

error according to Sobel's formula.

# **Arguments**

object an object inheriting from class "test\_mediation" containing results from (robust) mediation analysis, or a list of such objects.

... additional arguments to be passed down.

grid an optional numeric vector containing the values at which to evaluate the assumed normal density from Sobel's test. The default is to take 512 equally spaced points between the estimated indirect effect ± three times the standard

density\_plot 19

level

numeric; the confidence level of the confidence intervals from Sobel's test. The default is to include 95% confidence intervals. Note that this is not used for bootstrap tests, as those require to specify the confidence level already in test\_mediation().

#### **Details**

Methods first call setup\_density\_plot() to extract all necessary information to produce the plot, then the "setup\_density\_plot" method is called to produce the plot.

#### Value

An object of class "ggplot".

                            level = 0.9,
                            robust = FALSE)
```

20 ellipse\_plot

ellipse\_plot

Diagnostic plot with a tolerance ellipse

#### Description

Produce a scatter plot of two variables used in (robust) mediation analysis together with a tolerance ellipse. Exploiting the relationship between the regression coefficients and the covariance matrix, that tolerance ellipse illustrates how well the regression results represent the data. In addition, a line that visualizes the estimated regression coefficient is added when relevant.

# Usage

```
ellipse_plot(object, ...)

## Default S3 method:
ellipse_plot(
  object,
  horizontal = NULL,
  vertical = NULL,
  partial = FALSE,
  level = 0.975,
  npoints = 100,
   ...
)

## S3 method for class 'setup_ellipse_plot'
ellipse_plot(object, ...)
```

# Arguments

object an object inheriting from class "fit\_mediation" or "test\_mediation" con-

taining results from (robust) mediation analysis, or a list of such objects.

... additional arguments to be passed down.

horizontal a character string specifying the variable to be plotted on the horizontal axis. If

the dependent variable is chosen for the vertical axis, a hypothsized mediator or an independent variable must be selected for the horizontal axis. If a hypothesized mediator is chosen for the vertical axis, an independent variable must be ellipse\_plot 21

	selected for the horizontal axis (in case of a serial multiple mediator model, a hypothesized mediator occurring earlier in the sequence is also allowed). The default is to plot the first independent variable on the horizontal axis.
vertical	a character string specifying the variable to be plotted on the vertical axis: the dependent variable or a hypothesized mediator. The default is to plot the first hypothesized mediator on the vertical axis.
partial	a logical indicating whether the vertical axis should display the observed values of the selected variable (FALSE), or the partial residuals with respect to the variable on the horizontal axis (TRUE). The latter allows to display the corresponding regression coefficient by a line.
level	numeric; the confidence level of the tolerance ellipse. It gives the percentage of observations that are expected to lie within the ellipse under the assumption of a normal distribution, and therefore it controls the size of the ellipse. The default is such that the ellipse is expected to contain 97.5% of the observations.
npoints	the number of grid points used to evaluate and draw the ellipse. The default is to use 100 grid points.

### **Details**

A line to visualize the corresponding regression coefficient is added if partial = TRUE, or in case of a simple mediation model (without control variables) when the hypothesized mediator is plotted on the vertical axis and the independent variable is plotted on the horizontal axis.

For robust estimation methods that return outlyingness weights for each data point, those weights are visualized by coloring the points on a grey scale. If a list of objects has been supplied and there are multiple objects from such robust methods, each method is placed in a separate panel.

Methods first call setup\_ellipse\_plot() to extract all necessary information to produce the plot, then the "setup\_ellipse\_plot" method is called to produce the plot.

# Value

An object of class "ggplot".

# Author(s)

Andreas Alfons

fit\_mediation

(Robustly) fit a mediation model

### **Description**

(Robustly) estimate the effects in a mediation model.

# Usage

```
fit_mediation(object, ...)
## S3 method for class 'formula'
fit_mediation(formula, data, ...)
```

fit mediation 23

```
## Default S3 method:
fit_mediation(
  object,
  x,
  y,
  m,
  covariates = NULL,
  method = c("regression", "covariance"),
  robust = TRUE,
  family = "gaussian",
  model = c("parallel", "serial"),
  contrast = FALSE,
  fit_yx = TRUE,
  control = NULL,
  ...
)
```

### **Arguments**

object the first argument will determine the method of the generic function to be dispatched. For the default method, this should be a data frame containing the

variables.

... additional arguments to be passed down. For the default method, this can be

used to specify tuning parameters directly instead of via control.

formula an object of class "formula" (or one that can be coerced to that class): a symbolic

description of the model to be fitted. Hypothesized mediator variables should be wrapped in a call to m() (see examples), and any optional control variables

should be wrapped in a call to covariates().

data for the formula method, a data frame containing the variables.

x a character, integer or logical vector specifying the columns of object contain-

ing the independent variables of interest.

y a character string, an integer or a logical vector specifying the column of object

containing the dependent variable.

m a character, integer or logical vector specifying the columns of object contain-

ing the hypothesized mediator variables.

covariates optional; a character, integer or logical vector specifying the columns of object

containing additional covariates to be used as control variables.

method a character string specifying the method of estimation. Possible values are

"regression" (the default) to estimate the effects via regressions, or "covariance" to estimate the effects via the covariance matrix. Note that the effects are always estimated via regressions if more than one independent variable or hypothesized

mediator is specified, or if control variables are supplied.

robust a logical indicating whether to robustly estimate the effects (defaults to TRUE).

For estimation via regressions (method = "regression"), this can also be a character string, with "MM" specifying the MM-estimator of regression, and

"median" specifying median regression.

24 fit mediation

family a character string specifying the error distribution to be used in maximum likelihood estimation of regression models. Possible values are "gaussian" for a normal distribution (the default), skewnormal for a skew-normal distribution, "student" for Student's t distribution, "skewt" for a skew-t distribution, or "select" to select among these four distributions via BIC (see 'Details'). This is only relevant if method = "regression" and robust = FALSE.

a character string specifying the type of model in case of multiple mediators. Possible values are "parallel" (the default) for the parallel multiple mediator model, or "serial" for the serial multiple mediator model. This is only relevant for models with multiple hypothesized mediators, which are currently only implemented for estimation via regressions (method = "regression").

a logical indicating whether to compute pairwise contrasts of the indirect effects (defaults to FALSE). This can also be a character string, with "estimates" for computing the pairwise differences of the indirect effects, and "absolute" for computing the pairwise differences of the absolute values of the indirect effects. This is only relevant for models with multiple indirect effects, which are currently only implemented for estimation via regressions (method = "regression"). For models with multiple independent variables of interest and multiple hypothesized mediators, contrasts are only computed between indirect effects corresponding to the same independent variable.

a logical indicating whether to fit the regression model  $y \sim x + covariates$  to estimate the total effect (the default is TRUE). This is only relevant if method = "regression" and robust = FALSE.

a list of tuning parameters for the corresponding robust method. For the robust MM-estimator of regression (method = "regression", and robust = TRUE or robust = "MM"), a list of tuning parameters for lmrob() as generated by MM\_reg\_control(). For median regression (method = "regression", and robust = "median"), a list of tuning parameters for rq() as generated by median\_reg\_control(). For winsorized covariance matrix estimation (method = "covariance" and robust = TRUE), a list of tuning parameters for cov\_Huber() as generated by cov\_control().

### Details

With method = "regression", and robust = TRUE or robust = "MM", the effects are computed via the robust MM-estimator of regression from lmrob(). This is the default behavior.

With method = "regression" and robust = "median", the effects are estimated via median regressions with rq(). Unlike the robust MM-regressions above, median regressions are not robust against outliers in the explanatory variables.

With method = "regression", robust = FALSE and family = "select", the error distribution to be used in maximum likelihood estimation of the regression models is selected via BIC. The following error distributions are included in the selection procedure: a normal distribution, a skew-normal distribution, Student's t distribution, and a skew-t distribution. Note that the parameters of those distributions are estimated as well. The skew-normal and skew-t distributions thereby use a centered parametrization such that the residuals are (approximately) centered around 0. Moreover, the skew-t distribution is only evaluated in the selection procedure if both the skew-normal and Student's t distribution yield an improvement in BIC over the normal distribution. Otherwise the estimation with a skew-t error distribution can be unstable. Furthermore, this saves a considerable

contrast

model

fit\_yx

control

fit\_mediation 25

amount of computation time in a bootstrap test, as estimation with those error distributions is orders of magnitude slower than any other implemented estimation procedure.

With method = "covariance" and robust = TRUE, the effects are estimated based on a Huber Mestimator of location and scatter. Note that this covariance-based approach is less robust than the approach based on robust MM-regressions described above.

### Value

robust

sions.

An object inheriting from class "fit\_mediation" (class "reg\_fit\_mediation" if method = "regression" or "cov\_fit\_mediation" if method = "covariance") with the following components:

or "cov_fit_mediation" if method = "covariance") with the following components:		
a	a numeric vector containing the point estimates of the effects of the independent variables on the proposed mediator variables.	
b	a numeric vector containing the point estimates of the direct effects of the proposed mediator variables on the dependent variable.	
d	in case of a serial multiple mediator model, a numeric vector containing the point estimates of the effects of proposed mediator variables on other mediator variables occurring later in the sequence (only "reg_fit_mediation" if applicable).	
total	a numeric vector containing the point estimates of the total effects of the independent variables on the dependent variable.	
direct	a numeric vector containing the point estimates of the direct effects of the independent variables on the dependent variable.	
indirect	a numeric vector containing the point estimates of the indirect effects.	
ab	for back-compatibility with versions <0.10.0, the point estimates of the indirect effects are also included here. <b>This component is deprecated and may be removed as soon as the next version.</b>	
fit_mx	an object of class "lmrob", "rq", "lm" or "lmse" containing the estimation results from the regression of the proposed mediator variable on the independent variables, or a list of such objects in case of more than one hypothesized mediator (only "reg_fit_mediation").	
fit_ymx	an object of class "lmrob", "rq", "lm" or "lmse" containing the estimation results from the regression of the dependent variable on the proposed mediator and independent variables (only "reg_fit_mediation").	
fit_yx	an object of class "lm" or "lmse" containing the estimation results from the regression of the dependent variable on the independent variables (only "reg_fit_mediation" if arguments robust = FALSE and fit_yx = TRUE were used).	
cov	an object of class "cov_Huber" or "cov_ML" containing the covariance matrix estimates (only "cov_fit_mediation").	
x, y, m, covariates		
	character vectors specifying the respective variables used.	
data	a data frame containing the independent, dependent and proposed mediator variables, as well as covariates.	

either a logical indicating whether the effects were estimated robustly, or one of

the character strings "MM" and "median" specifying the type of robust regres-

26 fit mediation

a character string specifying the type of mediation model fitted: "simple" in case of one independent variable and one hypothesized mediator, "multiple" in case of multiple independent variables and one hypothesized mediator, "parallel" in case of parallel multiple mediators, or "serial" in case of serial multiple mediators (only "reg\_fit\_mediation").

contrast

either a logical indicating whether contrasts of the indirect effects were computed, or one of the character strings "estimates" and "absolute" specifying the type of contrasts of the indirect effects (only "reg\_fit\_mediation").

control

a list of tuning parameters used (if applicable).

#### Mediation models

The following mediation models are implemented. In the regression equations below, the  $i_j$  are intercepts and the  $e_j$  are random error terms.

• Simple mediation model: The mediation model in its simplest form is given by the equations

$$M = i_1 + aX + e_1,$$
  
 $Y = i_2 + bM + cX + e_2,$   
 $Y = i_3 + c'X + e_3,$ 

where Y denotes the dependent variable, X the independent variable, and M the hypothesized mediator. The main parameter of interest is the product of coefficients ab, called the indirect effect. The coefficients c and c' are called the direct and total effect, respectively.

• Parallel multiple mediator model: The simple mediation model can be extended with multiple mediators  $M_1, \ldots, M_k$  in the following way:

$$M_1 = i_1 + a_1 X + e_1,$$

$$\vdots$$

$$M_k = i_k + a_k X + e_k,$$

$$Y = i_{k+1} + b_1 M_1 + \dots + b_k M_k + cX + e_{k+1},$$

$$Y = i_{k+2} + c'X + e_{k+2}.$$

The main parameters of interest are the individual indirect effects  $a_1b_1, \ldots, a_kb_k$ .

• Serial multiple mediator model: It differs from the parallel multiple mediator model in that it allows the hypothesized mediators  $M_1, \ldots, M_k$  to influence each other in a sequential manner. It is given by the equations

$$M_1 = i_1 + a_1 X + e_1,$$
 
$$M_2 = i_1 + d_{21} M_1 + a_2 X + e_2,$$
 
$$\vdots$$
 
$$M_k = i_k + d_{k1} M_1 + \dots + d_{k,k-1} M_{k-1} + a_k X + e_k,$$
 
$$Y = i_{k+1} + b_1 M_1 + \dots + b_k M_k + c X + e_{k+1},$$
 
$$Y = i_{k+2} + c' X + e_{k+2}.$$

fit\_mediation 27

The serial multiple mediator model quickly grows in complexity with increasing number of mediators due to the combinatorial increase in indirect paths through the mediators. It is therefore only implemented for two and three mediators to maintain a focus on easily interpretable models. For two serial mediators, the three indirect effects  $a_1b_1$ ,  $a_2b_2$ , and  $a_1d_{21}b_2$  are the main parameters of interest. For three serial mediators, there are already seven indirect effects:  $a_1b_1$ ,  $a_2b_2$ ,  $a_3b_3$ ,  $a_1d_{21}b_2$ ,  $a_1d_{31}b_3$ ,  $a_2d_{32}b_3$ , and  $a_1d_{21}d_{32}b_3$ .

• Multiple independent variables to be mediated: The simple mediation model can also be extended by allowing multiple independent variables  $X_1, \ldots, X_l$  instead of multiple mediators. It is defined by the equations

$$M = i_1 + a_1 X_1 + \dots + a_l X_l + e_1,$$

$$Y = i_2 + bM + c_1 X_1 + \dots + c_l X_l + e_2,$$

$$Y = i_3 + c'_1 X_1 + \dots + c'_l X_l + e_3.$$

The indirect effects  $a_1b, \ldots, a_lb$  are the main parameters of interest. Note that an important special case of this model occurs when a categorical independent variable is represented by a group of dummy variables.

- Control variables: To isolate the effects of the independent variables of interest from other factors, control variables can be added to all regression equations of a mediation model. Note that there is no intrinsic difference between independent variables of interest and control variables in terms of the model or its estimation. The difference is purely conceptual in nature: for the control variables, the estimates of the direct and indirect paths are not of particular interest to the researcher. Control variables can therefore be specified separately from the independent variables of interest. Only for the latter, results for the indirect effects are included in the output.
- *More complex models*: Some of the models described above can be combined, for instance parallel and serial multiple mediator models support multiple independent variables of interest and control variables.

#### Note

The default method takes a data frame its first argument so that it can easily be used with the pipe operator (R's built-in |> or magrittr's %>%).

                               serial_m(TaskConflict,
                                        TeamCommitment) +
                               ValueDiversity,
                             data = BSG2014)
```

m 29

Create an object of hypothesized mediators or control variables

# Description

m

m() and its wrappers parallel\_m() and serial\_m() create an object of hypothesized mediators, while covariates() creates an object of control variables. Usually, these are used in a formula specifying a mediation model.

# Usage

```
m(..., .model = c("parallel", "serial"))
parallel_m(...)
serial_m(...)
covariates(...)
```

### **Arguments**

. . . variables are supplied as arguments, as usual separated by a comma.

.model a character string specifying the type of model in case of multiple mediators.

Possible values are "parallel" (the default) for the parallel multiple mediator model, or "serial" for the serial multiple mediator model.

### **Details**

m() and covariates() are essentially wrappers for cbind() with a specific class prepended to the class(es) of the resulting object.

parallel\_m() and serial\_m() are wrappers for m() with the respective value for argument . model.

30 plot-methods

### Value

m() returns an object inheriting from class "mediators" (with subclass "parallel\_mediators" or "serial\_mediators" as specified by argument .model), and covariates() returns an object of class "covariates". Typically, these inherit from class "matrix".

```

### **Examples**

plot-methods

Plot (robust) mediation analysis results

# **Description**

Visualize results from (robust) mediation analysis.

### Usage

```
## S3 method for class 'fit_mediation'
autoplot(object, which = c("ellipse", "weight"), ...)

## S3 method for class 'test_mediation'
autoplot(object, which = c("ci", "density", "ellipse", "weight"), ...)

## S3 method for class 'fit_mediation'
plot(x, which = c("ellipse", "weight"), ...)

## S3 method for class 'test_mediation'
plot(x, which = c("ci", "density", "ellipse", "weight"), ...)
```

plot-methods 31

### Arguments

an object inheriting from class "fit\_mediation" or "test\_mediation" containing results from (robust) mediation analysis.

which a character string specifying which plot to produce. Possible values are "ci" for
a dot plot of selected effects together with confidence intervals (see ci\_plot()),
 "density" for a density plot of the indirect effect(s) (see density\_plot()),
 "ellipse" for a diagnostic plot of the data together with a tolerance ellipse
 (see ellipse\_plot()), and "weight" for a diagnostic plot of robust regression
 weights (see weight\_plot()).

... additional arguments to be passed down.

### **Details**

The "fit\_mediation" method calls ellipse\_plot() or weight\_plot(), depending on the argument which.

The "test\_mediation" method calls ci\_plot(), density\_plot(), ellipse\_plot(), or weight\_plot(), depending on the argument which.

#### Value

An object of class "ggplot".

#### Author(s)

Andreas Alfons

#### References

plot(boot, which = "weight")
```

p\_value

p-Values from (robust) mediation analysis

# **Description**

Compute or extract the p-values for effects in (robust) mediation analysis.

# Usage

```
p_value(object, ...)
## S3 method for class 'boot_test_mediation'
p_value(object, parm = NULL, type = c("boot", "data"), digits = 4L, ...)
## S3 method for class 'sobel_test_mediation'
p_value(object, parm = NULL, ...)
```

### **Arguments**

object	an object inheriting from class "test_mediation" containing results from (robust) mediation analysis.
• • •	for the generic function, additional arguments to be passed down to methods. For the methods, additional arguments are currently ignored.
parm	an integer, character or logical vector specifying the paths for which to extract or compute p-values, or NULL to extract or compute p-values for all coefficients. In case of a character vector, possible values are "a", "b", "d" (only serial multiple mediator models), "total", "direct", and "indirect".
type	a character string specifying how to compute the p-values of the effects other than the indirect effect(s). Possible values are "boot" (the default) to compute bootstrap p-values using the normal approximation (i.e., to assume a normal distribution of the corresponding effect with the standard deviation computed from the bootstrap replicates), or "data" to compute p-values via statistical theory based on the original data (e.g., based on a t-distribution if the coefficients are

digits an

as described in 'Details'.

an integer determining how many digits to compute for the p-values of the indirect effects (see 'Details'). The default is to compute 4 digits after the comma.

estimated via regression). Note that this is only relevant for mediation analysis via a bootstrap test, where the p-value of the indirect effect is always computed

reg\_control 33

### **Details**

For bootstrap tests, the p-value of the indirect effect is computed as the smallest significance level  $\alpha$  for which the  $(1-\alpha)*100\%$  confidence interval obtained from the bootstrapped distribution does not contain 0.

This is a simple implementation, where each digit after the comma is determined via a grid search. Hence computation time can be long if confidence intervals are computed via the bias-corrected and accelerated method ("bca").

For Sobel tests, the p-value of the indirect effect is already stored in the object returned by test\_mediation() and is simply extracted.

#### Value

A numeric vector containing the requested p-values.

# Author(s)

Andreas Alfons

```

# **Examples**

reg\_control

Tuning parameters for robust regression

# **Description**

Obtain a list with tuning paramters for the robust MM-estimator of regression from lmrob() or median regression from rq().

34 reg\_control

#### Usage

```
reg_control(efficiency = 0.85, max_iterations = 200, tol = 1e-07, seed = NULL)

MM_reg_control(
   efficiency = 0.85,
   max_iterations = 200,
   tol = 1e-07,
   seed = NULL
)

median_reg_control(algorithm = "br")
```

#### **Arguments**

efficiency a numeric value giving the desired efficiency (defaults to 0.85 for 85% effi-

ciency).

max\_iterations an integer giving the maximum number of iterations in various parts of the al-

gorithm.

tol a small positive numeric value to be used to determine convergence in various

parts of the algorithm.

seed optional initial seed for the random number generator (see .Random.seed).

algorithm a character string specifying the algorithm for computing the median regression

fit. See argument method in rq() for options. If you experience an infinite loop

with the default algorithm ("br"), you may want to try "fn".

#### **Details**

Prior to version 1.2.0, the MM-estimator of regression was the only type of robust regression in **robmed** that supported control parameters. Starting with version 1.2.0, control parameters can also be passed to median regression, specifically the type of algorithm to be used. Function reg\_control() is an alias for MM\_reg\_control() for backwards compatibility, but it is now recommended to use MM\_reg\_control() when performing MM-regression and median\_reg\_control() when performing median regression.

#### Value

For MM\_reg\_control() and reg\_control(), a list of control parameters for the MM-estimator of regression as returned by lmrob.control().

For median\_reg\_control(), a list of control parameters for median regression.

#### Note

MM\_reg\_control() and its alias reg\_control() is a simplified wrapper function for lmrob.control(), as the latter requires detailed knowledge of the algorithm for the MM-estimator of regression. Currently only 95%, 90%, 85% (the default) and 80% efficiency are supported. For other values, please specify the corresponding tuning parameters in lmrob.control() directly.

#### **Examples**

retest

Retest for mediation

# **Description**

Re-perform a test for the indirect effect(s) based on results from (robust) mediation analysis. This function is purely available for computational convenience if the analysis was accidentally run with the wrong parameter settings, as it avoids having to re-run the bootstrap procedure. It must not be abused for p-hacking.

### Usage

```
retest(object, ...)
## S3 method for class 'boot_test_mediation'
retest(object, alternative, level, type, contrast, ...)
## S3 method for class 'sobel_test_mediation'
retest(object, alternative, order, ...)
```

36 retest

#### **Arguments**

object an object inheriting from class "test\_mediation" containing results from (ro-

bust) mediation analysis.

... additional arguments to be passed down to methods.

alternative a character string specifying the alternative hypothesis in the test for the indirect

effect. Possible values are "twosided", "less" or "greater".

level numeric; the confidence level of the confidence interval in the bootstrap test.

type a character string specifying the type of confidence interval to be computed in

the bootstrap test. Possible values are "perc" for the percentile bootstrap, or

"bca" for the bias-corrected and accelerated (BCa) bootstrap.

contrast a logical indicating whether to compute pairwise contrasts of the indirect effects.

This can also be a character string, with "estimates" for computing the pairwise differences of the indirect effects (such that it is tested whether two indirect effects are equal), and "absolute" for computing the pairwise differences of the absolute values of the indirect effects (such that it is tested whether two indirect effects are equal in magnitude). This is only relevant for models with multiple indirect effects, which are currently only implemented for bootstrap tests and

estimation via regressions.

order a character string specifying the order of approximation of the standard error in

Sobel's test. Possible values are "first" for a first-order approximation, and

"second" for a second-order approximation.

#### Value

An object of the same class as object with updated test results (see test\_mediation()).

#### Note

From version 0.9.0 onwards, the behavior of this function changed. For arguments that are not supplied, the corresponding values of object are now used as defaults.

Since version 1.1.0, bias-corrected and accelerated (BCa) bootstrap confidence intervals are no longer recommended, and the option type = "bca" may disappear in the future.

setup\_ci\_plot 37

setup\_ci\_plot

Set up information for a dot plot with confidence intervals

# **Description**

Extract the relevant information for a dot plot with confidence intervals of selected effects from (robust) mediation analysis. Information on p-values of the selected effects can be included in addition to confidence intervals.

## Usage

```
setup_ci_plot(object, ...)
## S3 method for class 'boot_test_mediation'
setup_ci_plot(
  object,
  parm = c("direct", "indirect"),
  type = c("boot", "data"),
  p_value = FALSE,
  digits = 4L,
)
## S3 method for class 'sobel_test_mediation'
setup_ci_plot(
 object,
  parm = c("direct", "indirect"),
  level = 0.95,
 p_value = FALSE,
)
## S3 method for class 'list'
setup_ci_plot(object, ...)
```

38 setup\_ci\_plot

#### **Arguments**

object an object inheriting from class "test\_mediation" containing results from (ro-

bust) mediation analysis, or a list of such objects.

... additional arguments to be passed down.

parm an integer, character or logical vector specifying which effects to include in the

plot. In case of a character vector, possible values are "a", "b", "d" (only serial multiple mediator models), "total", "direct", and "indirect". The default

is to include the direct and the indirect effect(s).

type a character string specifying which point estimates and confidence intervals to

plot: those based on the bootstrap distribution ("boot"; the default), or those based on the original data ("data"). If "boot", the confidence intervals of effects other than the indirect effect(s) are computed using a normal approximation (i.e., assuming a normal distribution of the corresponding effect with the standard deviation computed from the bootstrap replicates). If "data", the confidence intervals of effects other than the indirect effect(s) are computed via statistical theory based on the original data (e.g., based on a t-distribution if the coefficients are estimated via regression). Note that this is only relevant for mediation analysis via a bootstrap test, where the confidence interval of the indirect effect is always computed via a percentile-based method due to the asymmetry

of its distribution.

p\_value a logical indicating whether to include information on the p-values in addition

to the confidence intervals. The default is FALSE.

digits an integer determining how many digits to compute for bootstrap p-values of

the indirect effects (see p\_value()). The default is to compute 4 digits after the

comma. This is only relevant if p\_value = TRUE.

level numeric; the confidence level of the confidence intervals from Sobel's test.

The default is to include 95% confidence intervals. Note that this is not used for bootstrap tests, as those require to specify the confidence level already in

test\_mediation().

#### Details

This function is used internally by ci\_plot(). It may also be useful for users who want to produce a similar plot, but who want more control over what information to display or how to display that information.

#### Value

An object of class "setup\_ci\_plot" with the following components:

ci

a data frame consisting of column Effect indicating the different effects, column Estimate containing the point estimates, column Lower for the lower confidence limit, and column Upper for the upper confidence limit. If argument p\_value = TRUE, there is an additional column Label which gives the default facet label for the confidence intervals. If a list of "test\_mediation" objects has been supplied, there is also a column Method, which takes the names or indices of the list elements to indicate the different methods.

setup\_ci\_plot 39

p\_value a data frame consisting of column Label which gives the default facet label

for the p-values, column Effect indicating the different effects, and column Value containing the p-values. If a list of "test\_mediation" objects has been supplied, there is also a column Method, which takes the names or indices of the list elements to indicate the different methods. This is only returned if argument

p\_value = TRUE.

level numeric; the confidence level used for the confidence intervals of the indirect

effect(s).

have\_methods a logical indicating whether a list of "test\_mediation" objects has been sup-

plied. If TRUE, the data frame in the ci component contains a column Method.

40 setup\_density\_plot

setup\_density\_plot

*Set up information for a density plot of the indirect effect(s)* 

## **Description**

Extract the relevant information for a density plot of the indirect effect(s) from results of (robust) mediation analysis.

# Usage

```
setup_density_plot(object, ...)
## S3 method for class 'boot_test_mediation'
setup_density_plot(object, ...)
## S3 method for class 'sobel_test_mediation'
setup_density_plot(object, grid = NULL, level = 0.95, ...)
## S3 method for class 'list'
setup_density_plot(object, ...)
```

## **Arguments**

object	an object inheriting from class "test_mediation" containing results from (robust) mediation analysis, or a list of such objects.
	additional arguments to be passed down.
grid	an optional numeric vector containing the values at which to evaluate the assumed normal density from Sobel's test. The default is to take 512 equally spaced points between the estimated indirect effect $\pm$ three times the standard error according to Sobel's formula.
level	numeric; the confidence level of the confidence intervals from Sobel's test. The default is to include 95% confidence intervals. Note that this is not used for bootstrap tests, as those require to specify the confidence level already in test_mediation().

# **Details**

This function is used internally by density\_plot(). It may also be useful for users who want to produce a similar plot, but who want more control over what information to display or how to display that information.

#### Value

An object of class "setup\_density\_plot" with the following components:

setup\_density\_plot 41

density a data frame containing the values of the indirect effect where the density is esti-

mated (column Indirect), and the estimated density values (column Density). In case of a model with multiple indirect effects, there is a column Effect that indicates the different indirect effects. If a list of "test\_mediation" objects has been supplied, there is also a column Method, which takes the names or indices

of the list elements to indicate the different methods.

ci a data frame consisting of column Estimate containing the point estimates,

column Lower for the lower confidence limit, and column Upper for the upper confidence limit. In case of a model with multiple indirect effects, there is a column Effect that indicates the different indirect effects. If a list of "test\_mediation" objects has been supplied, there is also a column Method, which takes the names or indices of the list elements to indicate the different

methods.

test a character string indicating whether the object contains results from a bootstrap

test ("boot") or a Sobel test ("sobel"), or a vector of such character strings if a

list of "test\_mediation" objects has been supplied.

level numeric; the confidence level used for the confidence intervals of the indirect

effect(s).

have\_effects a logical indicating whether the mediation model contains multiple indirect ef-

fects If TRUE, the data frames in the density and ci components contain a col-

umn Effect.

have\_methods a logical indicating whether a list of "test\_mediation" objects has been sup-

plied. If TRUE, the data frames in the density and ci components contain a

column Method.

setup\_ellipse\_plot

Set up a diagnostic plot with a tolerance ellipse

# Description

Extract the relevant information for a diagnostic plot with a tolerance ellipse from results of (robust) mediation analysis.

## Usage

```
setup_ellipse_plot(object, ...)
## S3 method for class 'test_mediation'
setup_ellipse_plot(object, ...)
## S3 method for class 'reg_fit_mediation'
setup_ellipse_plot(
 object,
 horizontal = NULL,
 vertical = NULL,
 partial = FALSE,
 level = 0.975,
 npoints = 100,
)
## S3 method for class 'cov_fit_mediation'
setup_ellipse_plot(
  object,
 horizontal = NULL,
 vertical = NULL,
 partial = FALSE,
 level = 0.975,
 npoints = 100,
```

setup\_ellipse\_plot 43

```
## S3 method for class 'list'
setup_ellipse_plot(object, ...)
```

#### **Arguments**

object an object inheriting from class "fit\_mediation" or "test\_mediation" con-

taining results from (robust) mediation analysis, or a list of such objects.

... additional arguments to be passed down.

horizontal a character string specifying the variable to be plotted on the horizontal axis. If

the dependent variable is chosen for the vertical axis, a hypothsized mediator or an independent variable must be selected for the horizontal axis. If a hypothesized mediator is chosen for the vertical axis, an independent variable must be selected for the horizontal axis (in case of a serial multiple mediator model, a hypothesized mediator occurring earlier in the sequence is also allowed). The

default is to plot the first independent variable on the horizontal axis.

vertical a character string specifying the variable to be plotted on the vertical axis: the

dependent variable or a hypothesized mediator. The default is to plot the first

hypothesized mediator on the vertical axis.

partial a logical indicating whether to extract the observed values of the selected vari-

able for the vertical axis (FALSE), or the partial residuals with respect to the variable on the horizontal axis (TRUE). The latter allows to display the corresponding

regression coefficient by a line.

level numeric; the confidence level of the tolerance ellipse. It gives the percentage of

observations that are expected to lie within the ellipse under the assumption of a normal distribution, and therefore it controls the size of the ellipse. The default

is such that the ellipse is expected to contain 97.5% of the observations.

npoints the number of grid points used to evaluate the ellipse. The default is to use 100

grid points.

# Details

This function is used internally by ellipse\_plot(). It may also be useful for users who want to produce a similar plot, but who want more control over what information to display or how to display that information.

#### Value

An object of class "setup\_ellipse\_plot" with the following components:

data

a data frame containing the coordinates of the data points to be plotted on the horizontal axis (column x) and the coordinates on the vertical axis (column y). For robust methods that assign outlyingness weights to each data point, those weights are given in column Weight. If a list of objects has been supplied and there are multiple objects from such robust methods, or if partial residuals are to be plotted on the vertical axis, there is also a column Method, which takes the names or indices of the list elements to indicate the different methods.

44 setup\_ellipse\_plot

ellipse a data frame containing the coordinates of the tolerance ellipse on the horizontal

axis (column x) and on the vertical axis (column y). If a list of objects has been supplied, there is also a column Method, which takes the names or indices of the

list elements to indicate the different methods.

line a data frame with columns intercept and slope containing the intercept and

slope, respectively, of the regression line to be plotted. If a list of objects has been supplied, there is also a column Method, which takes the names or indices of the list elements to indicate the different methods. This is only returned if partial = TRUE, or in case of a simple mediation model (without control variables) when the hypothesized mediator is plotted on the vertical axis and the

independent variable is plotted on the horizontal axis.

horizontal a character string giving the variable to be plotted on the horizontal axis.

vertical a character string giving the variable to be plotted on the vertical axis

partial a logical indicating whether the values to be plotted on the vertical axis cor-

respond to the observed values of the selected variable (FALSE), or the partial

residuals with respect to the variable on the horizontal axis (TRUE).

robust a logical indicating whether the object contains results from a robust method, or

a vector of such logicals if a list of objects has been supplied.

have\_methods a logical indicating whether a list of objects has been supplied.

setup\_weight\_plot 45

setup\_weight\_plot

Set up a diagnostic plot of robust regression weights

# **Description**

Extract the relevant information for a diagnostic plot of the regression weights from robust mediation analysis. This plot allows to easily detect deviations from normality assumptions such as skewness or heavy tails.

# Usage

```
setup_weight_plot(object, ...)
## S3 method for class 'test_mediation'
setup_weight_plot(object, ...)
## S3 method for class 'reg_fit_mediation'
setup_weight_plot(object, outcome = NULL, npoints = 1000, ...)
```

# **Arguments**

object	an object inheriting from class "fit_mediation" or "test_mediation" containing results from robust mediation analysis. Only mediation analysis objects fitted with the robust MM-estimator are supported.
	additional arguments to be passed down.
outcome	a character vector specifying the outcome variables of the regressions to be included in the plot. This must be a subset of the hypothesized mediators and the dependent variable, or NULL (the default) to include all regressions of the mediation model.
npoints	the number of grid points used to evaluate the expected percentages. The default is to use 1000 grid points.

# **Details**

This function is used internally by weight\_plot(). It may also be useful for users who want to produce a similar plot, but who want more control over what information to display or how to display that information.

46 setup\_weight\_plot

## Value

An object of class "setup\_weight\_plot" with the following components:

data a data frame containing the following information: the outcome variable of the

regression (column Outcome; only if multiple regressions are to be included in the plot), whether the row corresponds to the negative or the positive tail of the residual distribution (column Tail), whether the row corresponds to the expected (under the normal distribution) or the empirical weights (column Weights), the weight thresholds (column Threshold), and the corresponding percentage

a character vector containing the outcome variables of the regressions to be in-

of observations that have a weight below this threshold (column Percentage).

cluded in the plot.

fit_mediation(), test_mediation(), weight_plot()
```

sim\_mediation

Generate data from a fitted mediation model

## **Description**

Generate data from a fitted mediation model, using the obtained coefficient estimates as the true model coefficients for data generation.

## Usage

```
sim_mediation(object, n, ...)
## S3 method for class 'fit_mediation'
sim_mediation(
  object.
  n = NULL
  explanatory = c("sim", "boot"),
  errors = c("sim", "boot"),
  num_discrete = 10,
)
## S3 method for class 'test_mediation'
sim_mediation(object, n = NULL, ...)
rmediation(n, object, ...)
```

## **Arguments**

object	an object inheriting from class "fit_mediation" or "test_mediation" con-
	taining nearlte from (naharat) and disting an alasia

taining results from (robust) mediation analysis.

n an integer giving the number of observations to be generated. If NULL (the de-

fault), the number of observations is taken from the data set used in the fitted mediation model from object.

additional arguments to be passed down.

explanatory a character string specifying how to generate the explanatory variables (i.e., the

independent variables and additional covariates). Possible values are "sim" to draw each explanatory variable independently from a certain distribution (the default), or "boot" to bootstrap the explanatory variables from the observed data (i.e., random sampling with replacement). See 'Details' for more information

on how the data are generated.

errors a character string specifying how to generate the error terms in the linear models

for the mediators and the dependent variable. Possible values are "sim" to draw the error terms independently from the respective fitted model distribution (the default), or "boot" to bootstrap the error terms from the observed residuals in the respective fitted model (i.e., random sampling with replacement). See

'Details' for more information on how the data are generated.

num\_discrete

integer; if the explanatory variables are drawn from distributions (explanatory = "sim"), variables that take num\_discrete or fewer values are considered discrete (the default is 10). In that case, the corresponding variables are drawn from multinomial distributions with the relative frequencies from the observed data. This is only relevant if the mediation model was fitted via regressions and ignored if the mediation model was fitted via the covariance matrix, as the latter method assumes multivariate normality.

## Details

The data generating process consists of three basic steps:

- 1. Generate the explanatory variables (i.e., the independent variables and additional covariates).
- 2. Generate the error terms of the different regression models.
- 3. Generate the mediators and the dependent variable from the respective regression models, using the coefficient estimates from the fitted mediation model as the true model coefficients.

If explanatory = "sim", the explanatory variables are simulated as follows. For each variable, a regression on a constant term is performed, using the same estimator and assumed error distribution as in the fitted mediation model from object. Typically, the assumed error distribution is normal, but it can also be a skew-normal, t, or skew-t distribution, or a selection of the best-fitting error distribution. Using the obtained location estimate and parameter estimates of the assumed error distribution, values are drawn from this error distribution and added to the location estimate. It is important to note that all explanatory variables are simulated independently from each other, hence there are no correlations between the explanatory variables.

In order to generate correlated explanatory variables, it is recommended bootstrap the explanatory variables from the observed data by setting explanatory = "boot".

If errors = "sim", the error terms of the different regression models are drawn from the assumed error distribution in the fitted mediation model from object, using the respective parameter estimates. Typically, the assumed error distribution is normal, but it can also be a skew-normal, t, or skew-t distribution, or a selection of the best-fitting error distribution.

If errors = "boot", bootstrapping the error terms from the observed residuals is done independently for the different regression models and, if also explanatory = "boot", independently from bootstrapping the explanatory variables.

The "boot\_test\_mediation" method for results of a bootstrap test always uses the regression coefficient estimates obtained on the original data for data generation, not the bootstrap estimates. Keep in mind that all bootstrap estimates are the means of the respective bootstrap replicates. If the bootstrap estimates of the regression coefficients were used to generate the data, the true values of the indirect effects for the generated data (i.e., the products of the corresponding bootstrap coefficient estimates) would not be equal to the reported bootstrap estimates of the indirect effects in object, which could lead to confusion. For the estimates on the original data, it of course holds that the estimates of indirect effects are the products of the corresponding coefficient estimates.

## Value

A data frame with n observations containing simulated data for the variables of the fitted mediation model.

#### **Mediation models**

The following mediation models are implemented. In the regression equations below, the  $i_j$  are intercepts and the  $e_j$  are random error terms.

• Simple mediation model: The mediation model in its simplest form is given by the equations

$$M = i_1 + aX + e_1,$$
  
 $Y = i_2 + bM + cX + e_2,$   
 $Y = i_3 + c'X + e_3,$ 

where Y denotes the dependent variable, X the independent variable, and M the hypothesized mediator. The main parameter of interest is the product of coefficients ab, called the indirect effect. The coefficients c and c' are called the direct and total effect, respectively.

• Parallel multiple mediator model: The simple mediation model can be extended with multiple mediators  $M_1, \ldots, M_k$  in the following way:

$$M_1 = i_1 + a_1 X + e_1,$$

$$\vdots$$

$$M_k = i_k + a_k X + e_k,$$

$$Y = i_{k+1} + b_1 M_1 + \dots + b_k M_k + c X + e_{k+1},$$

$$Y = i_{k+2} + c' X + e_{k+2}.$$

The main parameters of interest are the individual indirect effects  $a_1b_1, \ldots, a_kb_k$ .

• Serial multiple mediator model: It differs from the parallel multiple mediator model in that it allows the hypothesized mediators  $M_1, \ldots, M_k$  to influence each other in a sequential manner. It is given by the equations

$$M_1 = i_1 + a_1 X + e_1,$$
 
$$M_2 = i_1 + d_{21} M_1 + a_2 X + e_2,$$
 
$$\vdots$$
 
$$M_k = i_k + d_{k1} M_1 + \dots + d_{k,k-1} M_{k-1} + a_k X + e_k,$$
 
$$Y = i_{k+1} + b_1 M_1 + \dots + b_k M_k + c X + e_{k+1},$$
 
$$Y = i_{k+2} + c' X + e_{k+2}.$$

The serial multiple mediator model quickly grows in complexity with increasing number of mediators due to the combinatorial increase in indirect paths through the mediators. It is therefore only implemented for two and three mediators to maintain a focus on easily interpretable models. For two serial mediators, the three indirect effects  $a_1b_1$ ,  $a_2b_2$ , and  $a_1d_{21}b_2$  are the main parameters of interest. For three serial mediators, there are already seven indirect effects:  $a_1b_1$ ,  $a_2b_2$ ,  $a_3b_3$ ,  $a_1d_{21}b_2$ ,  $a_1d_{31}b_3$ ,  $a_2d_{32}b_3$ , and  $a_1d_{21}d_{32}b_3$ .

• Multiple independent variables to be mediated: The simple mediation model can also be extended by allowing multiple independent variables  $X_1, \ldots, X_l$  instead of multiple mediators. It is defined by the equations

$$M = i_1 + a_1 X_1 + \dots + a_l X_l + e_1,$$

$$Y = i_2 + bM + c_1 X_1 + \dots + c_l X_l + e_2,$$

$$Y = i_3 + c'_1 X_1 + \dots + c'_l X_l + e_3.$$

The indirect effects  $a_1b, \ldots, a_lb$  are the main parameters of interest. Note that an important special case of this model occurs when a categorical independent variable is represented by a group of dummy variables.

- Control variables: To isolate the effects of the independent variables of interest from other factors, control variables can be added to all regression equations of a mediation model. Note that that there is no intrinsic difference between independent variables of interest and control variables in terms of the model or its estimation. The difference is purely conceptual in nature: for the control variables, the estimates of the direct and indirect paths are not of particular interest to the researcher. Control variables can therefore be specified separately from the independent variables of interest. Only for the latter, results for the indirect effects are included in the output.
- *More complex models*: Some of the models described above can be combined, for instance parallel and serial multiple mediator models support multiple independent variables of interest and control variables.

#### Note

Function sim\_mediation() takes the object containing results from mediation analysis as its first argument so that it can easily be used with the pipe operator (R's built-in |> or magrittr's %>%).

Function rmediation() is a wrapper conforming with the naming convention for functions that generate data, as well as the convention of those function to take the number of observations as the first argument.

summary.test\_mediation

Summary of results from (robust) mediation analysis

## **Description**

Summarize results from (robust) mediation analysis for proper interpretation.

# Usage

```
## S3 method for class 'boot_test_mediation'
summary(object, type = c("boot", "data"), plot = TRUE, ...)
## S3 method for class 'sobel_test_mediation'
summary(object, ...)
```

#### **Arguments**

object an object inheriting from class "test\_mediation" containing results from (ro-

bust) mediation analysis.

type a character string specifying how to summarize the effects other than the indirect

effect(s). Possible values are "boot" (the default) to compute significance tests using the normal approximation of the bootstrap distribution (i.e., to assume a normal distribution of the corresponding effect with the standard deviation computed from the bootstrap replicates), or "data" to compute significance tests via statistical theory based on the original data (e.g., t-tests if the coefficients are estimated via regression). Note that this is only relevant for mediation analysis via a bootstrap test, where significance of the indirect effect is always assessed via a percentile-based confidence interval due to the asymmetry of its distribution.

plot a logical indicating whether to include a diagnostic plot of robust regression

weights (see weight\_plot()). This is only used for mediation analysis objects fitted with the robust MM-estimator (see test\_mediation()). Note that the diagnostic plot is only shown when the returned object is printed in order to maintain a clear separation between computing results and printing/plotting

them.

... additional arguments are currently ignored.

#### Value

An object of class "summary\_test\_mediation" with the following components:

object the object passed to the summary method, which contains the results from test-

ing the indirect effect(s).

summary an object containing all necessary information to summarize the effects other

than the indirect effect(s).

plot if applicable, an object inheriting from class "ggplot" containing the diagnostic

plot.

robmed(..., test = "boot", method = "regression", robust = TRUE)
```

## **Arguments**

object

the first argument will determine the method of the generic function to be dispatched. For the default method, this should be a data frame containing the variables. There is also a method for a mediation model fit as returned by fit\_mediation().

. . .

additional arguments to be passed down. For the bootstrap tests, those can be used to specify arguments of boot(), for example for parallel computing.

formula

an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model to be fitted. Hypothesized mediator variables should be wrapped in a call to m() (see examples), and any optional control variables should be wrapped in a call to covariates().

data

for the formula method, a data frame containing the variables.

test

a character string specifying the test to be performed for the indirect effects. Possible values are "boot" (the default) for the bootstrap, or "sobel" for Sobel's test. Currently, Sobel's test is not implemented for models with multiple indirect effects.

alternative

a character string specifying the alternative hypothesis in the test for the indirect effects. Possible values are "twosided" (the default), "less" or "greater".

56 test mediation

R an integer giving the number of bootstrap replicates. The default is to use 5000 bootstrap replicates. level numeric; the confidence level of the confidence interval in the bootstrap test. The default is to compute a 95% confidence interval. a character string specifying the type of confidence interval to be computed in type the bootstrap test. Possible values are "perc" (the default) for the percentile bootstrap, or "bca" for the bias-corrected and accelerated (BCa) bootstrap. order a character string specifying the order of approximation of the standard error in Sobel's test. Possible values are "first" (the default) for a first-order approximation, and "second" for a second-order approximation. method a character string specifying the method of estimation for the mediation model. Possible values are "regression" (the default) to estimate the effects via regressions, or "covariance" to estimate the effects via the covariance matrix. Note that the effects are always estimated via regressions if more than one independent variable or hypothesized mediator is specified, or if control variables are supplied. a logical indicating whether to perform a robust test (defaults to TRUE). For esrobust timation via regressions (method = "regression"), this can also be a character string, with "MM" specifying the MM-estimator of regression, and "median" specifying median regression. family a character string specifying the error distribution to be used in maximum likelihood estimation of regression models. Possible values are "gaussian" for a normal distribution (the default), skewnormal for a skew-normal distribution, "student" for Student's t distribution, "skewt" for a skew-t distribution, or "select" to select among these four distributions via BIC (see fit\_mediation() for details). This is only relevant if method = "regression" and robust = FALSE. contrast a logical indicating whether to compute pairwise contrasts of the indirect effects (defaults to FALSE). This can also be a character string, with "estimates" for computing the pairwise differences of the indirect effects (such that it is tested whether two indirect effects are equal), and "absolute" for computing the pairwise differences of the absolute values of the indirect effects (such that it is tested whether two indirect effects are equal in magnitude). This is only relevant for models with multiple indirect effects, which are currently only implemented for estimation via regressions (method = "regression"). For models with multiple independent variables of interest and multiple hypothesized mediators, contrasts are only computed between indirect effects corresponding to the same independent variable. fit\_yx a logical indicating whether to fit the regression model y ~ x + covariates to estimate the total effect (the default is TRUE). This is only relevant if method = "regression" and robust = FALSE. control a list of tuning parameters for the corresponding robust method. For the robust MM-estimator of regression (method = "regression", and robust = TRUE or robust = "MM"), a list of tuning parameters for lmrob() as generated by

MM\_reg\_control(). For median regression (method = "regression", and robust = "median"), a list of tuning parameters for rq() as generated by median\_reg\_control().

test mediation 57

	For winsorized covariance matrix estimation (method = "covariance" and robust = TRUE), a list of tuning parameters for cov_Huber() as generated by cov_control().
x	a character, integer or logical vector specifying the columns of object containing the independent variables of interest.
у	a character string, an integer or a logical vector specifying the column of object containing the dependent variable.
m	a character, integer or logical vector specifying the columns of object containing the hypothesized mediator variables.
covariates	optional; a character, integer or logical vector specifying the columns of object containing additional covariates to be used as control variables.
model	a character string specifying the type of model in case of multiple mediators. Possible values are "parallel" (the default) for the parallel multiple mediator model, or "serial" for the serial multiple mediator model. This is only relevant for models with multiple hypothesized mediators, which are currently only implemented for estimation via regressions (method = "regression").

#### **Details**

With method = "regression", and robust = TRUE or robust = "MM", the tests are based on robust regressions with the MM-estimator from lmrob(). The bootstrap test is thereby performed via the fast-and-robust bootstrap. This is the default behavior.

Note that the MM-estimator of regression implemented in lmrob() can be seen as weighted least squares estimator, where the weights are dependent on how much an observation is deviating from the rest. The trick for the fast-and-robust bootstrap is that on each bootstrap sample, first a weighted least squares estimator is computed (using those robustness weights from the original sample) followed by a linear correction of the coefficients. The purpose of this correction is to account for the additional uncertainty of obtaining the robustness weights.

With method = "regression" and robust = "median", the tests are based on median regressions with rq(). Note that the bootstrap test is performed via the standard bootstrap, as the fast-and-robust bootstrap is not applicable. Unlike the robust regressions described above, median regressions are not robust against outliers in the explanatory variables, and the standard bootstrap can suffer from oversampling of outliers in the bootstrap samples.

With method = "covariance" and robust = TRUE, the tests are based on a Huber M-estimator of location and scatter. For the bootstrap test, the M-estimates are used to first clean the data via a transformation. Then the standard bootstrap is performed with the cleaned data. Note that this covariance-based approach is less robust than the approach based on robust regressions described above. Furthermore, the bootstrap does not account for the variability from cleaning the data.

robmed() is a wrapper function for performing robust mediation analysis via regressions and the fast-and-robust bootstrap.

## Value

An object inheriting from class "test\_mediation" (class "boot\_test\_mediation" if test = "boot" or "sobel\_test\_mediation" if test = "sobel") with the following components:

a a numeric vector containing the bootstrap point estimates of the effects of the independent variables on the proposed mediator variables (only "boot\_test\_mediation"). 58 test\_mediation

b	a numeric vector containing the bootstrap point estimates of the direct effects of the proposed mediator variables on the dependent variable (only "boot_test_mediation").
d	in case of a serial multiple mediator model, a numeric vector containing the bootstrap point estimates of the effects of proposed mediator variables on other mediator variables occurring later in the sequence (only "boot_test_mediation" if applicable.
total	a numeric vector containing the bootstrap point estimates of the total effects of the independent variables on the dependent variable (only "boot_test_mediation").
direct	a numeric vector containing the bootstrap point estimates of the direct effects of the independent variables on the dependent variable (only "boot_test_mediation").
indirect	a numeric vector containing the bootstrap point estimates of the indirect effects (only "boot_test_mediation").
ab	for back-compatibility with versions <0.10.0, the bootstrap point estimates of the indirect effects are also included here (only "boot_test_mediation"). This component is deprecated and may be removed as soon as the next version.
ci	a numeric vector of length two or a matrix of two columns containing the bootstrap confidence intervals for the indirect effects (only "boot_test_mediation").
reps	an object of class "boot" containing the bootstrap replicates (only "boot_test_mediation"). For regression model fits, bootstrap replicates of the coefficients in the individual regression models are stored.
se	numeric; the standard error of the indirect effect according to Sobel's formula (only "sobel_test_mediation").
statistic	numeric; the test statistic for Sobel's test (only "sobel_test_mediation").
p_value	numeric; the p-value from Sobel's test (only "sobel_test_mediation").
alternative	a character string specifying the alternative hypothesis in the test for the indirect effects.
R	an integer giving the number of bootstrap replicates (only "boot_test_mediation").
level	$numeric; the confidence \ level \ of \ the \ bootstrap \ confidence \ interval \ (only \ "boot\_test\_mediation").$
type	a character string specifying the type of bootstrap confidence interval (only "boot_test_mediation").
fit	an object inheriting from class "fit_mediation" containing the estimation results of the mediation model on the original data.

# **Mediation models**

The following mediation models are implemented. In the regression equations below, the  $i_j$  are intercepts and the  $e_j$  are random error terms.

• Simple mediation model: The mediation model in its simplest form is given by the equations

$$M = i_1 + aX + e_1,$$
  
 $Y = i_2 + bM + cX + e_2,$   
 $Y = i_3 + c'X + e_3,$ 

test mediation 59

where Y denotes the dependent variable, X the independent variable, and M the hypothesized mediator. The main parameter of interest is the product of coefficients ab, called the indirect effect. The coefficients c and c' are called the direct and total effect, respectively.

• Parallel multiple mediator model: The simple mediation model can be extended with multiple mediators  $M_1, \ldots, M_k$  in the following way:

$$M_{1} = i_{1} + a_{1}X + e_{1},$$

$$\vdots$$

$$M_{k} = i_{k} + a_{k}X + e_{k},$$

$$Y = i_{k+1} + b_{1}M_{1} + \dots + b_{k}M_{k} + cX + e_{k+1},$$

$$Y = i_{k+2} + c'X + e_{k+2}.$$

The main parameters of interest are the individual indirect effects  $a_1b_1, \ldots, a_kb_k$ .

• Serial multiple mediator model: It differs from the parallel multiple mediator model in that it allows the hypothesized mediators  $M_1, \ldots, M_k$  to influence each other in a sequential manner. It is given by the equations

$$M_1 = i_1 + a_1 X + e_1,$$
 
$$M_2 = i_1 + d_{21} M_1 + a_2 X + e_2,$$
 
$$\vdots$$
 
$$M_k = i_k + d_{k1} M_1 + \dots + d_{k,k-1} M_{k-1} + a_k X + e_k,$$
 
$$Y = i_{k+1} + b_1 M_1 + \dots + b_k M_k + c X + e_{k+1},$$
 
$$Y = i_{k+2} + c' X + e_{k+2}.$$

The serial multiple mediator model quickly grows in complexity with increasing number of mediators due to the combinatorial increase in indirect paths through the mediators. It is therefore only implemented for two and three mediators to maintain a focus on easily interpretable models. For two serial mediators, the three indirect effects  $a_1b_1$ ,  $a_2b_2$ , and  $a_1d_{21}b_2$  are the main parameters of interest. For three serial mediators, there are already seven indirect effects:  $a_1b_1$ ,  $a_2b_2$ ,  $a_3b_3$ ,  $a_1d_{21}b_2$ ,  $a_1d_{31}b_3$ ,  $a_2d_{32}b_3$ , and  $a_1d_{21}d_{32}b_3$ .

• Multiple independent variables to be mediated: The simple mediation model can also be extended by allowing multiple independent variables  $X_1, \ldots, X_l$  instead of multiple mediators. It is defined by the equations

$$M = i_1 + a_1 X_1 + \dots + a_l X_l + e_1,$$

$$Y = i_2 + bM + c_1 X_1 + \dots + c_l X_l + e_2,$$

$$Y = i_3 + c'_1 X_1 + \dots + c'_l X_l + e_3.$$

The indirect effects  $a_1b, \ldots, a_lb$  are the main parameters of interest. Note that an important special case of this model occurs when a categorical independent variable is represented by a group of dummy variables.

60 test\_mediation

• Control variables: To isolate the effects of the independent variables of interest from other factors, control variables can be added to all regression equations of a mediation model. Note that that there is no intrinsic difference between independent variables of interest and control variables in terms of the model or its estimation. The difference is purely conceptual in nature: for the control variables, the estimates of the direct and indirect paths are not of particular interest to the researcher. Control variables can therefore be specified separately from the independent variables of interest. Only for the latter, results for the indirect effects are included in the output.

• *More complex models*: Some of the models described above can be combined, for instance parallel and serial multiple mediator models support multiple independent variables of interest and control variables.

#### Note

For the fast-and-robust bootstrap, the simpler correction of Salibian-Barrera & Van Aelst (2008) is used rather than the originally proposed correction of Salibian-Barrera & Zamar (2002).

The default method takes a data frame its first argument so that it can easily be used with the pipe operator (R's built-in |> or magrittr's %>%).

Since version 1.1.0, bias-corrected and accelerated (BCa) bootstrap confidence intervals are no longer recommended, and the option type = "bca" may disappear in the future.

62 weights.cov\_Huber

weights.cov\_Huber

Robustness weights of Huber M-estimation of location and scatter

## **Description**

Extract (relative) robustness weights of a Huber M-estimate of location and scatter.

## Usage

```
## S3 method for class 'cov_Huber'
weights(object, type = c("consistent", "relative"), ...)
```

## **Arguments**

object an object inheriting from class "cov\_Huber" containing Huber M-estimates of

location and scatter.

type a character string specifying the type of robustness weights to be extracted. Pos-

sible values are "consistent" and "relative". The former can be used for a robust transformation of the data such that the covariance matrix of the transformed data is Fisher consistent. Observations that are not downweighted in general receive a weight larger than 1. The latter are useful for interpretation, as

observations that are not downweighted receive a relative weight of 1.

... additional arguments are currently ignored.

#### Value

A numeric vetor containing the requested robustness weights.

# Author(s)

Andreas Alfons

weight\_plot 63

# **Examples**

```
data("BSG2014")

# define variables
x <- "ValueDiversity"
y <- "TeamCommitment"
m <- "TaskConflict"

# compute Huber M-estimator
S <- cov_Huber(BSG2014[, c(x, y, m)])
weights(S, type = "relative")</pre>
```

weight\_plot

Diagnostic plot of robust regression weights

# Description

Produce a diagnostic plot of the regression weights from robust mediation analysis. This plot allows to easily detect deviations from normality assumptions such as skewness or heavy tails.

#### Usage

```
weight_plot(object, ...)
## Default S3 method:
weight_plot(object, outcome = NULL, npoints = 1000, ...)
## S3 method for class 'setup_weight_plot'
weight_plot(object, ...)
```

## **Arguments**

object an object inheriting from class "fit\_mediation" or "test\_mediation" containing results from robust mediation analysis. Only mediation analysis objects fitted with the robust MM-estimator are supported.

. . . additional arguments to be passed down.

64 weight\_plot

outcome a character vector specifying the outcome variables of the regressions to be in-

cluded in the plot. This must be a subset of the hypothesized mediators and the dependent variable, or NULL (the default) to include all regressions of the

mediation model.

npoints the number of grid points used to evaluate and draw the expected percentages.

The default is to use 1000 grid points.

#### **Details**

The horizontal axis contains different weight thresholds, and the vertical axis displays the percentage of observations that have a weight below this threshold. For comparison, a reference line is drawn for the expected percentages under normally distributed errors. Observations with negative and positive residuals are shown separately to make it possible to distinguish between symmetric and asymmetric deviations from normality.

If the plot reveals more downweighted observations than expected, but roughly the same amounts in both tails, the residual distribution is symmetric but with heavy tails. If the plot shows that observations in one tail are downweighted more heavily than those in the other tail, the residual distribution is skewed.

## Value

An object inheriting from class "ggplot".

#### Note

The current implementation is a slight hack of **ggplot2** and the **grid** graphics system in order to revert the horizontal axis only in the panels for observations with postive residuals. It is therefore not possible to change the horizontal axis with scale\_x\_continuous().

The implementation may change in the future if the required functionality becomes available in **ggplot2**.
