

Package ‘libr’

November 6, 2024

Type Package

Title Libraries, Data Dictionaries, and a Data Step for R

Version 1.3.7

Maintainer David Bosak <dbosak01@gmail.com>

Description Contains a set of functions to create data libraries, generate data dictionaries, and simulate a data step. The libname() function will load a directory of data into a library in one line of code. The dictionary() function will generate data dictionaries for individual data frames or an entire library. And the datestep() function will perform row-by-row data processing.

datastep	<i>Step through data row-by-row</i>
----------	-------------------------------------

Description

The `datastep` function allows you to perform row-wise conditional processing on a data frame, data table, or tibble. The function contains parameters to drop, keep, or rename variables, perform by-group processing, and perform row-wise or column-wise calculations.

Usage

```
datastep(  
  data,  
  steps,  
  keep = NULL,  
  drop = NULL,  
  rename = NULL,  
  by = NULL,  
  calculate = NULL,  
  retain = NULL,  
  attrib = NULL,  
  arrays = NULL,  
  sort_check = TRUE,  
  format = NULL,  
  label = NULL,  
  where = NULL,  
  set = NULL,  
  merge = NULL,  
  merge_by = NULL,  
  merge_in = NULL,  
  log = TRUE,  
  subset = NULL  
)
```

Arguments

data	The data to step through. This parameter is required. Valid values are a data frame or a NULL. In the case of a NULL, you must include at least one output() function in the steps.
steps	The operations to perform on the data. This parameter is specified as a set of R statements contained within curly braces. If no steps are desired, pass empty curly braces.
keep	A vector of quoted variable names to keep in the output data set. By default, all variables are kept.
drop	A vector of quoted variable names to drop from the output data set. By default, no variables are dropped.
rename	A named vector of quoted variables to rename. The current variable name should be on the left hand side of the name/value pair, and the new variable name should be on the right. The rename operation is performed after the data step, the keep, and the drop. Therefore, the data steps should use the input variable name. By default, all variables retain their original names.
by	A vector of quoted variable names to use for by-group processing. This parameter will activate the first. and last. automatic variables, that indicate the first or last rows in a group. These automatic variables are useful for conditional processing on groups. The function will also create first and last automatic variables for each variable specified in the by group.

calculate	Steps to set up calculated variables. Calculated variables are commonly generated with summary functions such as mean, median, min, max, etc. It is more efficient to set up calculated variables with the calculate parameter and then use those variables in the data step, rather than perform the summary function inside the data step. The calculate block will be executed immediately before the data step.
retain	A list of variable names and initial values to retain. Retained variables will begin the data step with the initial value. Then for each iteration of the data step, the variable will be populated with the ending value from the previous step. The retain functionality allows you to perform cumulative operations or decisions based on the value of the previous iteration of the data step. Initial values should be of the expected data type for the column. For example, for a numeric column set the initial value to a zero, and for a character column, set the initial value to an empty string, i.e. <code>retain = list(col1 = 0, col2 = "")</code> . There is no default initial value for a variable. You must supply an initial value for each retained variable.
attrib	A named list of attributes. The list can be either <code>dsattr</code> objects or single default values. The <code>dsattr</code> object allows you to set more attributes on each column. The single default value is convenient if you simply want to create a variable. By default, variables will be created on the fly with no attributes.
arrays	A named list of <code>dsarray</code> objects. The <code>dsarray</code> is a list of columns which you can iterate over inside the data step. You can iterate over a <code>dsarray</code> either with a for loop, or with a vectorized function. The default value of the arrays parameter is NULL, meaning no arrays are defined.
sort_check	Checks to see if the input data is sorted according to the by variable parameter. The sort check will give an error if the input data is not sorted according to the by variable. The check is turned on if the value of <code>sort_check</code> is TRUE, and turned off if FALSE. The default value is TRUE. Turn the sort check off if you want to perform by-group processing on unsorted data, or data that is not sorted according to the by-group.
format	A named list of formats to assign to the data frame. Formats will be assigned both before and after the datastep.
label	A named list of labels to assign to the output data frame.
where	An expression to filter the output dataset. The where clause will be applied prior to any drop, keep, or rename statement. Use the <code>expression</code> function to assign the where clause.
set	A dataset or list of datasets to append to the input data frame. The set operation will occur at the beginning of the datastep, prior to the execution of any steps. The columns in the set datasets do not have to match. Where there are no matching columns, the missing values will be filled with NA.
merge	A dataset or list of datasets to merge with the input data. The merge operation will occur at the beginning of the datastep, prior to the execution of any steps. When the merge operation is requested, the <code>merge_by</code> parameter will be used to indicate which variable(s) to merge by. If no <code>merge_by</code> is specified, the merge dataset columns will simply be appended to the right of the input dataset.

merge_by	If the merge parameter is set, the merge_by parameter will be used to identify the variable(s) to merge by. If merge variables are the same on both datasets, the names may be passed as a simple quoted vector. If the variable names are different, pass the variables to merge on as a named vector. For example, c("ITEMID" = "ITEMCODE") would specify that the join should occur on the "ITEMID" from the dataset specified in the data parameter, and the "ITEMCODE" variable from the dataset specified on the merge parameter.
merge_in	A vector of column names to be used to hold the merge flags. The number of names should correspond to the number of datasets being merged. The merge flags will be populated with 0 or 1 values to indicate whether the record came from the corresponding table. Use the where parameter, delete function, or output function to filter desired results.
log	Whether or not to log the datastep. Default is TRUE. This parameter is used internally.
subset	The subset parameter accepts an expression object that will be used to subset the data. The subset expression will be executed before the datastep executes. In this regard, the subset parameter on the R datastep is similar to the where clause on the SAS datastep.

Details

Two parameters on the datastep function are required: **data** and **steps**. The **data** parameter is the input data to the data step. The **steps** parameter contains the code statements you want to apply to the data. The **steps** should be wrapped in curly braces. When running, the data step will loop through the input data row-by-row, and execute the steps for each row. Variables inside the data step can be accessed using non-standard evaluation (meaning they do not have to be quoted).

Note that the data step is pipe-friendly. It can be used within a **dplyr** pipeline. The data step allows you to perform deeply nested and complex conditionals within the pipeline. The data step is also very readable compared to other pipeline conditionals.

Value

The processed data frame, tibble, or data table.

Automatic Variables

The datastep function provides five automatic variables. These variables are generated for every data step, and can be accessed at any point within the data step:

- **data**: Represents the entire input data frame.
- **rw**: Represents the current row.
- **n.**: Contains the row number.
- **first.**: Indicates the beginning of a by-group.
- **last.**: Indicates the end of a by-group.

Automatic variables will be dropped from the data frame at the end of the data step. If you wish to keep the automatic variable values, assign the automatic variable to a new variable and keep that variable.

If there are multiple by group variables, the `first.` and `last.` automatic variables indicates a either/or combination of all by variables. In addition, `first.X` and `last.X` automatic variables will be created for each variable, where "X" represents the name of the specified variable. As always, these names are case-sensitive.

Column Attributes

To set attributes for a column on your data, use the `attrib` parameter. Example attributes include `'label'`, `'description'`, and `'format'`. These types of attributes are set using a named list and a `dsattr` object. The name of the list item is the column name you want to set attributes on. The value of the list item is the `dsattr` object. For a complete list of available attributes, see the `dsattr` documentation.

It should be mentioned that the `dsattr` object is not required. You can also set attributes with a name and a default value. The default value can be any valid data value, such as a number or string.

The `label` and `format` attributes may also be set with the `'label'` and `'format'` parameters. These parameters accept a named list with the labels or formats, and will be assigned to the output data frame.

Optional Parameters

Optional parameters on the `datastep` allow you to shape the output dataset or enhance the operation of the `datastep`. Some parameters are classified as input parameters, and others as output parameters. Input parameters modify the data before the data step operations takes place. Output parameters operate on the data after the data step.

The `keep`, `drop`, and `rename` parameters are output parameters. These parameters will be applied after the data step statements are executed. Therefore, within the data step, refer to variables using the input variable name. New variables may be created on the fly, just by assigning a value to the new variable name.

The `keep`, `drop`, and `rename` parameters require quoted variable names, as the variables may not yet exist at the time they are passed into the function. Within a data step or `calculate` block, however, variable names do not need to be quoted.

The `calculate` parameter is used to perform vectorized functions on the data prior to executing the data step. For example, you may want to determine a mean for a variable in the `calculate` block, and then make decisions on that mean in the data step block.

The `retain` parameter allows you to access the prior row value. At the start of the data step, the retained variable is seeded with the initial value. For each subsequent step, the variable is seeded with the value of the prior step/row. This functionality allows you to increment values or perform cumulative operations.

`calculate` and `retain` are both input parameters.

The `subset` and `where` parameters can both be used to filter the `datastep` data. The difference is that `subset` is an input parameter, and `where` is an output parameter.

Set and Merge Operations

The `datastep` function allows you to join one or more input datasets into a single output dataset. There are two operations in this regard: `"set"` and `"merge"`. A `set` operation stacks the datasets vertically, one on top of another. The `merge` operation joins the datasets horizontally, left and right.

The `datastep` set and merge operations are unusually flexible compared to other join functions in R. The set operation does not require the same number of columns in each dataset. Likewise, the merge operation does not require the same number of rows. In both cases, where there is no corresponding column or row, the function will fill in with NA values.

The merge operation can perform both inner and outer joins. By default, the merge performs a full outer join. If you wish to limit the operation to an inner join, use the "merge_in" parameter to set up variables with which you can filter the desired rows. The "merge_in" variables will be populated with 1 or 0 values, which indicate whether or not the dataset contained that row. Once these variables are populated, you can easily limit the results using a where expression, or the `delete` or `output` functions from inside the `datastep`.

Data Step Arrays

There are times you may want to iterate over columns in your data step. Such iteration is particularly useful when you have a wide dataset, and wish to perform the same operation on several columns. For instance, you may want to calculate the mean for 10 different variables on your dataset.

The `arrays` parameter allows you to iterate across columns. This parameter accepts a named list of `dsarray` objects. The `dsarray` is essentially a list of columns. You can use a for loop to iterate over the `dsarray`, and also send it into a vectorized function. Data step arrays allow you to perform row-wise calculations. For instance, you can calculate a sum or mean by row for the variables in your array.

Output Column Order

By default, the data step will retain the column order of any variables that already exist on the input data set. New variables created in a data step will be appended to the right of existing variables. Yet these new variables can sometimes appear in an order that is unexpected or undesirable.

There are two ways to control the order of output columns: the `keep` parameter and the `attrib` parameter.

Columns names included on the `keep` parameter will appear in the order indicated on the `keep` vector. This ordering mechanism is appropriate when you have a small number of columns and can easily pass the entire `keep` list.

To control the order of new variables only, use the `attrib` parameter. New variables for which attributes are defined will appear in the order indicated on the `attrib` list. The `attrib` list is useful when you are adding a relatively small number of columns to an existing data set, and don't want to pass all the column names.

Remember that you can supply an attribute list with default values only, such as `attrib = list(column1 = 0, column2 = "")`. This style of attribute definition is convenient if you are only trying to control the order of columns.

If the above two mechanisms to control column order are not sufficient, use the data frame subset operators or column ordering functions provided by other packages.

Datastep Performance

The `datastep` is intended to be used on small and medium-sized datasets. It is not recommended for large datasets. If your dataset is greater than one million rows, you should consider other techniques

for processing your data. While there is no built-in restriction on the number of rows, performance of the datastep can become unacceptable with a large number of rows.

Examples

```
# Example #1: Simple Data Step
df <- datastep(mtcars[1:10,],
              keep = c("mpg", "cyl", "disp", "mpgcat", "recdt", "is8cyl"), {

  if (mpg >= 20)
    mpgcat <- "High"
  else
    mpgcat <- "Low"

  recdt <- as.Date("1974-06-10")

  if (cyl == 8)
    is8cyl <- TRUE
  else
    is8cyl <- FALSE

})

df
#           mpg cyl  disp mpgcat   recdt
# Mazda RX4      21.0  6 160.0   High 1974-06-10
# Mazda RX4 Wag  21.0  6 160.0   High 1974-06-10
# Datsun 710     22.8  4 108.0   High 1974-06-10
# Hornet 4 Drive  21.4  6 258.0   High 1974-06-10
# Hornet Sportabout 18.7  8 360.0   Low 1974-06-10
# Valiant        18.1  6 225.0   Low 1974-06-10
# Duster 360     14.3  8 360.0   Low 1974-06-10
# Merc 240D      24.4  4 146.7   High 1974-06-10
# Merc 230       22.8  4 140.8   High 1974-06-10
# Merc 280       19.2  6 167.6   Low 1974-06-10

# Example #2: By-group Processing
df <- datastep(mtcars[1:10,],
              keep = c("mpg", "cyl", "gear", "grp"),
              by = c("gear"), sort_check = FALSE, {

  if (first.)
    grp <- "Start"
  else if (last.)
    grp <- "End"
  else
    grp <- "-"

```

```

})

df
#           mpg cyl gear  grp
# Mazda RX4      21.0  6   4 Start
# Mazda RX4 Wag  21.0  6   4   -
# Datsun 710     22.8  4   4 End
# Hornet 4 Drive  21.4  6   3 Start
# Hornet Sportabout 18.7  8   3   -
# Valiant        18.1  6   3   -
# Duster 360     14.3  8   3 End
# Merc 240D      24.4  4   4 Start
# Merc 230       22.8  4   4   -
# Merc 280       19.2  6   4 End

# Example #3: Calculate Block
df <- datastep(mtcars,
               keep = c("mpg", "cyl", "mean_mpg", "mpgcat"),
               calculate = { mean_mpg = mean(mpg) }, {

  if (mpg >= mean_mpg)
    mpgcat <- "High"
  else
    mpgcat <- "Low"

})

df[1:10,]
#           mpg cyl mean_mpg mpgcat
# Mazda RX4      21.0  6 20.09062 High
# Mazda RX4 Wag  21.0  6 20.09062 High
# Datsun 710     22.8  4 20.09062 High
# Hornet 4 Drive  21.4  6 20.09062 High
# Hornet Sportabout 18.7  8 20.09062 Low
# Valiant        18.1  6 20.09062 Low
# Duster 360     14.3  8 20.09062 Low
# Merc 240D      24.4  4 20.09062 High
# Merc 230       22.8  4 20.09062 High
# Merc 280       19.2  6 20.09062 Low

# Example #4: Data pipeline
library(dplyr)
library(magrittr)

# Add datastep to dplyr pipeline
df <- mtcars %>%
  select(mpg, cyl, gear) %>%
  mutate(mean_mpg = mean(mpg)) %>%
  datastep({

    if (mpg >= mean_mpg)
      mpgcat <- "High"
  })

```

```

else
  mpgcat <- "Low"

}) %>%
filter(row_number() <= 10)

df
#   mpg cyl gear mean_mpg mpgcat
# 1  21.0  6   4 20.09062   High
# 2  21.0  6   4 20.09062   High
# 3  22.8  4   4 20.09062   High
# 4  21.4  6   3 20.09062   High
# 5  18.7  8   3 20.09062   Low
# 6  18.1  6   3 20.09062   Low
# 7  14.3  8   3 20.09062   Low
# 8  24.4  4   4 20.09062   High
# 9  22.8  4   4 20.09062   High
# 10 19.2  6   4 20.09062   Low

# Example #5: Drop, Retain and Rename
df <- datastep(mtcars[1:10, ],
  drop = c("disp", "hp", "drat", "qsec",
           "vs", "am", "gear", "carb"),
  retain = list(cumwt = 0 ),
  rename = c(mpg = "MPG", cyl = "Cylinders", wt = "Wgt",
             cumwt = "Cumulative Wgt"), {

  cumwt <- cumwt + wt

})

df
#           MPG Cylinders  Wgt Cumulative Wgt
# Mazda RX4      21.0         6 2.620         2.620
# Mazda RX4 Wag  21.0         6 2.875         5.495
# Datsun 710     22.8         4 2.320         7.815
# Hornet 4 Drive 21.4         6 3.215        11.030
# Hornet Sportabout 18.7         8 3.440        14.470
# Valiant        18.1         6 3.460        17.930
# Duster 360     14.3         8 3.570        21.500
# Merc 240D      24.4         4 3.190        24.690
# Merc 230       22.8         4 3.150        27.840
# Merc 280       19.2         6 3.440        31.280

# Example #6: Attributes and Arrays

# Create sample data
dat <- read.table(header = TRUE, text = '
Year Q1  Q2  Q3  Q4
2000 125 137 152 140
2001 132 145 138  87
2002 101 104 115 121')
```

```
# Use attrib list to control column order and add labels
# Use array to calculate row sums and means, and get best quarter
df <- datastep(dat,
  attrib = list(Tot = dsattr(0, label = "Year Total"),
               Avg = dsattr(0, label = "Year Average"),
               Best = dsattr(0, label = "Best Quarter")),
  arrays = list(qtrs = dsarray("Q1", "Q2", "Q3", "Q4")),
  drop = "q",
  steps = {

    # Empty brackets return all array values
    Tot <- sum(qtrs[])
    Avg <- mean(qtrs[])

    # Iterate to find best quarter
    for (q in qtrs) {
      if (qtrs[q] == max(qtrs[]))
        Best <- q
    }
  })
```

```
df
#   Year Q1 Q2 Q3 Q4 Tot   Avg Best
# 1 2000 125 137 152 140 554 138.50 Q3
# 2 2001 132 145 138  87 502 125.50 Q2
# 3 2002 101 104 115 121 441 110.25 Q4
```

```
dictionary(df)
# A tibble: 8 x 10
#   Name Column Class Label Description Format Width Justify Rows NAs
#   <chr> <chr> <chr> <chr> <chr> <lg1> <int> <chr> <int> <int>
# 1 df Year integer NA NA NA NA NA NA 3 0
# 2 df Q1 integer NA NA NA NA NA NA 3 0
# 3 df Q2 integer NA NA NA NA NA NA 3 0
# 4 df Q3 integer NA NA NA NA NA NA 3 0
# 5 df Q4 integer NA NA NA NA NA NA 3 0
# 6 df Tot integer Year Total NA NA NA NA 3 0
# 7 df Avg numeric Year Average NA NA NA NA 3 0
# 8 df Best character Best Quarter NA NA 2 NA 3 0
```

Example #7: Set and Merge Operations

```
# Create sample data
grp1 <- read.table(header = TRUE, text = '
GROUP NAME
G01 Group1
G02 Group2
', stringsAsFactors = FALSE)

grp2 <- read.table(header = TRUE, text = '
GROUP NAME
G03 Group3
G04 Group4
```

```

', stringsAsFactors = FALSE)

dat <- read.table(header = TRUE, text = '
  ID AGE SEX GROUP
  A01 58 F   G01
  A02 20 M   G02
  A03 47 F   G05
  A04 11 M   G03
  A05 23 F   G01
', stringsAsFactors = FALSE)

# Set operation
grps <- datastep(grp1, set = grp2, {})
grps
#   GROUP  NAME
# 1   G01 Group1
# 2   G02 Group2
# 3   G03 Group3
# 4   G04 Group4

# Merge operation - Outer Join
res <- datastep(dat, merge = grps,
                merge_by = "GROUP",
                merge_in = c("inA", "inB"), {})

# View results
res
#   ID AGE  SEX GROUP  NAME inA inB
# 1  A01 58   F   G01 Group1  1  1
# 2  A05 23   F   G01 Group1  1  1
# 3  A02 20   M   G02 Group2  1  1
# 4  A04 11   M   G03 Group3  1  1
# 5  A03 47   F   G05 <NA>  1  0
# 6 <NA> NA <NA> G04 Group4  0  1

# Merge operation - Inner Join
res <- datastep(dat, merge = grps,
                merge_by = "GROUP",
                merge_in = c("inA", "inB"),
                where = expression(inA & inB), {})

# View results
res
#   ID AGE  SEX GROUP  NAME inA inB
# 1  A01 58   F   G01 Group1  1  1
# 2  A05 23   F   G01 Group1  1  1
# 3  A02 20   M   G02 Group2  1  1
# 4  A04 11   M   G03 Group3  1  1

# Example #8: Data NULL

# Create new dataset using output() functions.
res <- datastep(NULL,

```

```
    {
      ID <- 10
      Item <- "Pencil"
      output()

      ID <- 20
      Item <- "Scissors"
      output()
    })

# View results
res
#   ID   Item
# 1  10 Pencil
# 2  20 Scissors
```

delete	<i>Removes an observation from a datastep</i>
--------	---

Description

The delete function will remove an observation from the output of a datastep. The function takes no parameters. To use the function, simply call it on the rows you want to delete. Typically it is called within a conditional.

Usage

```
delete()
```

Value

Observation is marked with a delete flag. No return value.

See Also

Other datastep: [[.dsarray\(\)](#), [datastep\(\)](#), [dsarray\(\)](#), [dsattr\(\)](#), [length.dsarray\(\)](#), [output\(\)](#)]

Examples

```
#' # Remove all cars that are not 4 cylinder
df <- datastep(mtcars,
               keep = c("mpg", "cyl", "disp"), {

  if (cyl != 4)
    delete()

})

df
#   mpg cyl  disp
```

```
# 1 22.8 4 108.0
# 2 24.4 4 146.7
# 3 22.8 4 140.8
# 4 32.4 4 78.7
# 5 30.4 4 75.7
# 6 33.9 4 71.1
# 7 21.5 4 120.1
# 8 27.3 4 79.0
# 9 26.0 4 120.3
# 10 30.4 4 95.1
# 11 21.4 4 121.0
```

dictionary

Create a Data Dictionary

Description

A function to create a data dictionary for a data frame, a tibble, or a data library. The function will generate a tibble of information about the data. The tibble will contain the following columns:

- **Name:** The name of the data object.
- **Column:** The name of the column.
- **Class:** The class of the column.
- **Label:** The value of the label attribute.
- **Description:** A description applied to this column.
- **Format:** The value of the format attribute.
- **Width:** The value of the width attribute if any have been assigned.
- **Justify:** The justification or alignment attribute value.
- **Rows:** The number of data rows.
- **NAs:** The number of NA values in this column.
- **MaxChar:** The maximum character length of the values in this column with no padding.

Usage

```
dictionary(x)
```

Arguments

x The input library, data frame, or tibble.

See Also

[libname](#) to create a data library. Also see the [dsattr](#) function to set attributes for your dataset from within a [datasteq](#). To render attributes, see the [fmtr](#) package.

Examples

```

# Create temp directory
tmp <- tempdir()

# Create library
libname(dat, tmp)

# Add data to the library
lib_add(dat, beaver1)
lib_add(dat, iris)

# Examine the dictionary for the library
dictionary(dat)
# A tibble: 9 x 10
#   Name      Column      Class  Label Description Format Width Justify Rows  NAs MaxChar
#   <chr>   <chr>      <chr>  <lgl> <lgl>      <lgl> <lgl> <lgl> <int> <int> <int>
# 1 beaver1 day          numeric NA    NA          NA    NA    NA    114    0     3
# 2 beaver1 time          numeric NA    NA          NA    NA    NA    114    0     4
# 3 beaver1 temp          numeric NA    NA          NA    NA    NA    114    0     5
# 4 beaver1 activ          numeric NA    NA          NA    NA    NA    114    0     1
# 5 iris    Sepal.Length numeric NA    NA          NA    NA    NA    150    0     3
# 6 iris    Sepal.Width  numeric NA    NA          NA    NA    NA    150    0     3
# 7 iris    Petal.Length numeric NA    NA          NA    NA    NA    150    0     3
# 8 iris    Petal.Width  numeric NA    NA          NA    NA    NA    150    0     3
# 9 iris    Species      factor  NA    NA          NA    NA    NA    150    0    10

# Clean up
lib_delete(dat)

```

dsarray*Create a Data Step Array*

Description

A data step array is an object that allows you to iterate across a set of columns inside a [datastep](#). This structure is useful when you need to perform the same or similar operations on many columns.

Usage

```
dsarray(...)
```

Arguments

... Column names to include as part of the datastep array. The names can be provided as quoted strings or a vector of strings. If names are provided as quoted strings, separate the strings with commas (i.e. `dsarray("col1", "col2", "col3")`).

Details

The `dat` array has an indexer that allows you to access a particular column value. The indexer can be used within a `for` loop to iterate over the array. In this manner, you can place a set of conditions inside the `for` loop and run the same conditional logic on all the columns in the array.

You can also use the `dat` array with an empty indexer in vectorized functions like `sum`, `mean`, and `max`. The empty indexer will return all the values in the array for the current row.

Value

The `dat` array object.

See Also

`libname` to create a data library, and `dictionary` for generating a data dictionary

Other `dat` step: `[.dsarray()`, `datstep()`, `delete()`, `dsattr()`, `length.dsarray()`, `output()`

Examples

```
library(libr)

# Create AirPassengers Data Frame
df <- as.data.frame(t(matrix(AirPassengers, 12,
                             dimnames = list(month.abb, seq(1949, 1960)))),
                    stringsAsFactors = FALSE)

# Use dat array to get year tot, mean, and top month
dat <- datstep(df,
               arrays = list(months = dsarray(names(df))),
               attrib = list(Tot = 0, Mean = 0, Top = ""),
               drop = "mth",
               {

                 Tot <- sum(months[])
                 Mean <- mean(months[])

                 for (mth in months) {
                   if (months[mth] == max(months[])) {
                     Top <- mth
                   }
                 }
               })

dsattr

*Assign Datasheet Variable Attributes***Description**

An object to assign attributes to a column in a [datasheet](#). The parameters allow you to set the following attributes: 'class', 'label', 'description', 'width', 'justify', and 'format'. Any other desired attributes can be set with . . .

The attributes available in the `dsattr` class are closely aligned with those available on the [dictionary](#) object.

Usage

```
dsattr(
  default = NA,
  label = NULL,
  description = NULL,
  width = NULL,
  format = NULL,
  justify = NULL,
  ...
)
```

Arguments

default	The default value of the column. The default value can be any valid data value. Typical default values might be an empty string ("") or a zero (0). If no default value is specified, the column will be defaulted to NA.
label	The label to associate with this column. Accepts any string value. The label will appear as a column header on some data viewers and reporting packages.
description	A description for this column. Accepts any string value. The description is intended to be a longer explanation of the purpose or source of the variable.
width	The desired width for the column in number of characters.
format	The format associated with this column. See the fmtr package for more information about formatting.
justify	The desired justification for the column. This parameter is normally used only for fixed-width, character columns. Valid values are 'left', 'right', 'center', and 'centre'.
. . .	Any other attributes you wish to assign to this column. Pass these additional attributes as a name/value pair.

Value

The data step attributes object.

See Also

[dictionary](#) function to observe the attributes associated with a dataset. Also see the `fdata` function in the **fmtr** package for more information on formatting and rendering data frames.

Other `datastep`: [\[.dsarray\(\)\]](#), [datastep\(\)](#), [delete\(\)](#), [dsarray\(\)](#), [length.dsarray\(\)](#), [output\(\)](#)

Examples

```
library(libr)

# Create small sample dataframe
dat <- mtcars[1:10, c("mpg", "cyl")]

# Perform datastep and assign attributes
dat1 <- datastep(dat,
  attrib = list(mpg = dsattr(label = "Miles Per Gallon"),
               cyl = dsattr(label = "Cylinders"),
               mpgcat = dsattr(label = "Fuel Efficiency")),
  {
    if (mpg >= 20)
      mpgcat = "High"
    else
      mpgcat = "Low"
  })

# Print results
dat1
#           mpg cyl mpgcat
# Mazda RX4      21.0   6   High
# Mazda RX4 Wag  21.0   6   High
# Datsun 710     22.8   4   High
# Hornet 4 Drive  21.4   6   High
# Hornet Sportabout 18.7   8   Low
# Valiant        18.1   6   Low
# Duster 360     14.3   8   Low
# Merc 240D      24.4   4   High
# Merc 230       22.8   4   High
# Merc 280       19.2   6   Low

# Examine label attributes
attr(dat1$mpg, "label")
# [1] "Miles Per Gallon"

attr(dat1$cyl, "label")
# [1] "Cylinders"
```

```
attr(dat1$mpgcat, "label")
# [1] "Fuel Efficiency"

# See labels in viewer
# View(dat1)
```

import_spec

Create an Import Specification

Description

A function to create the import specifications for a particular data file. This information can be used on the [libname](#) function to correctly assign the data types for columns on imported data. The import specifications are defined as name/value pairs, where the name is the column name and the value is the data type indicator. Available data type indicators are 'guess', 'logical', 'character', 'integer', 'numeric', 'date', 'datetime', and 'time'. See the [specs](#) function for an example of using import specs.

Usage

```
import_spec(..., na = NULL, trim_ws = NULL)
```

Arguments

...	Named pairs of column names and column data types. Available types are: 'guess', 'logical', 'character', 'integer', 'numeric', 'date', 'datetime', and 'time'. The date/time data types accept an optional input format. To supply the input format, append it after the data type following an equals sign, e.g.: 'date=%d%B%Y' or 'datetime=%d%m%Y %H:%M:%S'. Default is NULL, meaning no column types are specified, and the function should make its best guess for each column.
na	A vector of values to be treated as NA. For example, the vector c(' ', ' ') will cause empty strings and single blanks to be converted to NA values. Default is NULL, meaning the value of the na parameter will be taken from the specs function. Any value supplied on the import_spec function will override the value from the specs function.
trim_ws	Whether or not to trim white space from the input data values. The default is NULL, meaning the value of the trim_ws parameter will be taken from the specs function. Any value supplied on the import_spec function will override the value from the specs function.

Value

The import specification object.

See Also

[libname](#) to create a data library, and [specs](#) for an example using import specs.

Other specs: [print.specs\(\)](#), [read.specs\(\)](#), [specs\(\)](#), [write.specs\(\)](#)

is.lib	<i>Class test for a data library</i>
--------	--------------------------------------

Description

This function tests whether an object is a data library. The data library has a class of "lib".

Usage

```
is.lib(x)
```

Arguments

x The object to test.

Value

TRUE or FALSE, depending on whether or not the object is a data library.

See Also

Other lib: [lib_add\(\)](#), [lib_copy\(\)](#), [lib_delete\(\)](#), [lib_export\(\)](#), [lib_info\(\)](#), [lib_load\(\)](#), [lib_path\(\)](#), [lib_remove\(\)](#), [lib_replace\(\)](#), [lib_size\(\)](#), [lib_sync\(\)](#), [lib_unload\(\)](#), [lib_write\(\)](#), [libname\(\)](#), [print.lib\(\)](#)

Examples

```
# Create format catalog
libname(dat, tempdir())

# Test for "lib" class
is.lib(dat)
# [1] TRUE

is.lib(list())
# [1] FALSE

# Clean up
lib_delete(dat)
```

length.dsarray	<i>Length function for dsarray class</i>
----------------	--

Description

A length function for the data step array [dsarray](#). The length function can be used either inside or outside the data step.

Usage

```
## S3 method for class 'dsarray'
length(x)
```

Arguments

x The [dsarray](#) object.

Value

The number of items in the specified [dsarray](#).

See Also

Other [datastep](#): [\[.dsarray\(\)](#), [datastep\(\)](#), [delete\(\)](#), [dsarray\(\)](#), [dsattr\(\)](#), [output\(\)](#)

Examples

```
# Define datastep array
carr <- dsarray(names(mtcars))

length(carr)
# 11
```

libname	<i>Create a data library</i>
---------	------------------------------

Description

A data library is a collection of data sets. The purpose of the data library is to combine related data sets, and provides the opportunity to manipulate all of them as a single object. A data library is created using the `libname` function. The `libname` function allows you to load an entire directory of data into memory in one step. The **libr** package contains additional functions to add and remove data from the library, copy the library, and write any changed data to the file system.

Usage

```
libname(
  name,
  directory_path,
  engine = "rds",
  read_only = FALSE,
  env = parent.frame(),
  import_specs = NULL,
  filter = NULL,
  standard_eval = FALSE,
  quiet = FALSE,
  log = TRUE,
  where = NULL
)
```

Arguments

name	The unquoted name of the library to create. The library name will be created as a variable in the environment specified on the <code>env</code> parameter. The default environment is the parent frame. If you want to pass the library name as a quoted string or a variable, set the <code>standard_eval</code> parameter to <code>TRUE</code> to turn off the non-standard evaluation.
directory_path	A directory path to associate with the library. If the directory contains data files of the type specified on the <code>engine</code> parameter, they will be imported into the library list. If the directory does not contain data sets of the appropriate type, it will be created as an empty library. If the directory does not exist, it will be created by the <code>libname</code> function.
engine	The engine to associate with the library. The specified engine will be used to import and export data. The engine name corresponds to the standard file extension of the data file type. The default engine is <code>'rds'</code> . Valid values are <code>'rds'</code> , <code>'Rdata'</code> , <code>'rda'</code> , <code>'sas7bdat'</code> , <code>'xpt'</code> , <code>'xls'</code> , <code>'xlsx'</code> , <code>'dbf'</code> , <code>'csv'</code> , <code>'parquet'</code> .
read_only	Whether the library should be created as read-only. Default is <code>FALSE</code> . If <code>TRUE</code> , the user will be restricted from appending, removing, or writing any data from memory to the file system.
env	The environment to use for the <code>libname</code> . Default is <code>parent.frame()</code> . When working inside a function, the <code>parent.frame()</code> will refer to the local function scope. When working outside a function, the <code>parent.frame()</code> will be the global environment. If the <code>env</code> parameter is set to a custom environment, the custom environment will be used for all subsequent operations with that library name.
import_specs	A collection of import specifications, defined using the specs function. The import specs should be named according to the file names in the library directory. See the specs function for additional information.
filter	One or more quoted strings to use as filters for the incoming file names. For more than one filter string, pass them as a vector of strings. The filter string can be a full or partial file name, without extension. If using a partial file name,

	use a wild-card character (*) to identify the missing portion. The match will be case-insensitive.
standard_eval	A TRUE or FALSE value which indicates whether to use standard (quoted) or non-standard (unquoted) evaluation on the library name parameter. Use standard evaluation when you want to pass the library name with a variable. Default is FALSE.
quiet	When TRUE, minimizes output to the console when loading files. Default is FALSE.
log	Whether to log the libname operation. Default is TRUE. This parameter is used internally.
where	An expression used to subset all datasets in the library. The where clause will be executed when the library is created. Use the Base R expression function to define the subset. If a where clause is supplied, the library will be opened read-only.

Details

For most projects, a data file does not exist in isolation. There are sets of related files of the same file type. The aim of the `libname` function is to take advantage of this fact, and give you an easy way to manage the entire set.

The `libname` function points to a directory of data files, and associates a name with that set of data. The name refers to an object of class `'lib'`, which at its heart is a named list. When the `libname` function executes, it will load all the data in the directory into the list, and assign the file name (without extension) as the list item name. Data can be accessed using list syntax, or loaded directly into the local environment using the `lib_load` function.

The `libname` function provides several data engines to read data of different types. For example, there is an engine for Excel files, and another engine for SAS@ datasets. The engines are identified by the extension of the file type they handle. The available engines are `'rds'`, `'RData'`, `'rda'`, `'csv'`, `'xlsx'`, `'xls'`, `'sas7bdat'`, `'xpt'`, `'dbf'`, and `'parquet'`. Once an engine has been assigned to a library, all other read/write operations will be performed by that engine.

The data engines largely hide file import details from you. The purpose of the `libname` function is to make it easy to import a set of related data files that follow standard conventions. The function assumes that the data has file extensions that match the file type, and then makes further assumptions based on each type of file. As a result, there are very few import options on the `libname` function. If your data does not follow standard conventions, it is recommended that you import your data using a package that gives you more control over import options.

Value

The library object, with all data files loaded into the library list. Items in the list will be named according to the file name, minus the file extension.

Data Engines

The `libname` function currently provides seven different engines for seven different types of data files. Here is a complete list of available engines and some commentary about each:

- **rds**: For R data sets. This engine is the default. Because detailed data type and attribute information can be stored inside the rds file, the rds engine is the most reliable and easiest to use.
- **Rdata** and **rda**: Older R data storage formats. Like the 'rds' engine, these storage types retain column attributes and data types.
- **csv**: For comma separated value files. This engine assumes that the first row has column names, and that strings containing commas are quoted. Blank values and the string 'NA' will be interpreted as NA. Because data type information is not stored in csv files, the csv engine will attempt to guess the data types based on the available data. For most columns, the csv engine is able to guess accurately. Where it fails most commonly is with date and time columns. For csv date and time columns, it is therefore recommended to assign an import spec that tells the engine how to read the date or time. See the [specs](#) documentation for additional details.
- **xlsx**: For Excel files produced with the current version of Excel. Excel provides more data type information than csv, but it is not as accurate as rds. Therefore, you may also need to provide import specifications with Excel files. Also note that currently the xlsx import engine will only import the first sheet of an Excel workbook. If you need to import a sheet that is not the first sheet, use a different package to import the data.
- **xls**: An Excel file format used between 1997 and 2003, and still used in some organizations. As with xlsx, this file format provides more information than csv, but is not entirely reliable. Therefore, you may need to provide import specifications to the xls engine. Also note that the xls engine can read, but not write xls files. Any xls files read with the xls engine will be written as an xlsx file. Like the xlsx engine, the xls engine can only read the first sheet of a workbook.
- **sas7bdat**: Handles SAS® datasets. SAS® datasets provide better type information than either csv or Excel. In most cases, you will not need to define import specifications for SAS® datasets. The sas7bdat engine interprets empty strings, single blanks, and a single dot (".") as missing values. While the import of SAS® datasets is fairly reliable, sas7bdat files cannot be written or exported with the sas7bdat engine. In these cases, it is recommended to export to another file format, such as csv, dbf, or parquet, and then import into SAS®.
- **xpt**: The SAS® transport file engine. Transport format is a platform independent file format. Similar to SAS® datasets, it provides data type information. In most cases, you will not need to define import specifications. The xpt engine also interprets empty strings, single blanks, and a single dot (".") as missing values.
- **dbf**: The DBASE file format engine. The DBASE engine was added to the **libr** package because many types of software can read and write in DBASE format reliably. Therefore it is a useful file format for interchange between software systems. The DBASE file format contains type information.
- **parquet**: The parquet file format is an open source format supported by many languages and software. The format is strongly typed, and offers fast data storage and retrieval. The **libr** package can both read from and write to parquet files.

File Filters

If you wish to import only a portion of your data files into a library, you may accomplish it with the `filter` parameter. The filter parameter allows you to pass a vector of strings corresponding to the

names of the files you want to import. The function allows a wild-card (*) for partial matching. For example, "te*" means any file name that begins with a "te", and "*st" means any file name that ends with an "st".

Import Specifications

In most cases, it is not necessary to specify the data types for incoming columns in your data. Either the file format will preserve the appropriate data type information, or the assigned engine will guess correctly.

However, in some cases it will be necessary to control the column data types. For these cases, use the `import_specs` parameter. The `import_specs` parameter allows you to specify the data types by data set and column name. All the data type specifications are contained within a specs collection, and the specifications for a particular data set are defined by an `import_spec` function. See the [specs](#) and [import_spec](#) documentation for further information and examples of defining an import spec.

#Unload from workspace
lib_unload(dat)

# Clean up
lib_delete(dat)

```

lib_add

Add Data to a Data Library

Description

The `lib_add` function adds a data frame or tibble to an existing data library. The function will both add the data to the library list, and immediately write the data to the library directory location. The data will be written to disk in the file format associated with the library engine. If the library is loaded, the function will also add the data to the workspace environment.

Usage

```
lib_add(x, ..., name = NULL)
```

Arguments

<code>x</code>	The library to add data to.
<code>...</code>	The data frame(s) to add to the library. If more than one, separate with commas.
<code>name</code>	The reference name to use for the data. By default, the name will be the variable name. To assign a name different from the variable name, assign a quoted name to this parameter. If more than one data set is being appended, assign a vector of quoted names.

# Clean up
lib_delete(dat)
```

lib_copy

Copy a Data Library

Description

The `lib_copy` function copies a data library. The function accepts a library and a destination path. If the destination path does not exist, the function will attempt to create it.

Note that the copy will result in the current data in memory written to the new destination directory. If the library is loaded into the workspace, the workspace version will be considered the most current version, and that is the version that will be copied.

Usage

```
lib_copy(x, nm, directory_path, standard_eval = FALSE)
```

Arguments

x	The library to copy.
nm	The variable name to hold the new library. The parameter will assume non-standard (unquoted) evaluation unless the standard_eval parameter is set to TRUE.
directory_path	The path to copy the library to.
standard_eval	A TRUE or FALSE value which indicates whether to use standard (quoted) or non-standard (unquoted) evaluation on the nm parameter. Default is FALSE. Use this parameter if you want to pass the target library name in a variable.

Value

The new library.

See Also

Other lib: [is.lib\(\)](#), [lib_add\(\)](#), [lib_delete\(\)](#), [lib_export\(\)](#), [lib_info\(\)](#), [lib_load\(\)](#), [lib_path\(\)](#), [lib_remove\(\)](#), [lib_replace\(\)](#), [lib_size\(\)](#), [lib_sync\(\)](#), [lib_unload\(\)](#), [lib_write\(\)](#), [libname\(\)](#), [print.lib\(\)](#)

Examples

```
# Create temp directory
tmp <- tempdir()

# Create library
libname(dat1, tmp)

# Add dat to library
lib_add(dat1, mtcars, iris)

# Copy dat1 to dat2
lib_copy(dat1, dat2, file.path(tmp, "copy"))
# library 'dat2': 2 items
# - attributes: not loaded
# - path: C:\Users\User\AppData\Local\Temp\RtmpCSJ6Gc/copy
# - items:
#   Name Extension Rows Cols Size LastModified
# 1 mtcars rds 32 11 7.5 Kb 2020-11-05 21:14:54
# 2 iris rds 150 5 7.5 Kb 2020-11-05 21:14:54

# Clean up
lib_delete(dat1)
lib_delete(dat2)
```

lib_delete	<i>Delete a Data Library</i>
------------	------------------------------

Description

The `lib_delete` function deletes a data library from the file system and from memory. All data files associated with the library and the specified engine will be deleted. If other files exist in the library directory, they will not be affected by the delete operation.

The directory that contains the data will also not be affected by the delete operation. To delete the data directory, use the [unlink](#) function or other packaged functions.

Usage

```
lib_delete(x)
```

Arguments

`x` The data library to delete.

See Also

Other lib: [is.lib\(\)](#), [lib_add\(\)](#), [lib_copy\(\)](#), [lib_export\(\)](#), [lib_info\(\)](#), [lib_load\(\)](#), [lib_path\(\)](#), [lib_remove\(\)](#), [lib_replace\(\)](#), [lib_size\(\)](#), [lib_sync\(\)](#), [lib_unload\(\)](#), [lib_write\(\)](#), [libname\(\)](#), [print.lib\(\)](#)

Examples

```
# Create temp directory
tmp <- tempdir()

# Create library
libname(dat, tmp)

# Add data to library
lib_add(dat, mtcars)
lib_add(dat, iris)

# Load library
lib_load(dat)

# Examine workspace
ls()
# [1] "dat" "dat.iris" "dat.mtcars" "tmp"

# Examine library
dat
# library 'dat': 2 items
# - attributes: not loaded
# - path: C:\Users\User\AppData\Local\Temp\RtmpCSJ6Gc
```

```
# - items:
#   Name Extension Rows Cols   Size      LastModified
# 1 mtcars      rds   32   11 7.5 Kb 2020-11-05 21:18:17
# 2 iris       rds  150    5 7.5 Kb 2020-11-05 21:18:17

# Delete library
lib_delete(dat)

#' # Examine workspace again
ls()
# [1] "tmp"
```

lib_export

Export a Data Library

Description

The `lib_export` function exports a data library to another library with a different directory and file format. The function accepts a library to export, the new library name, a destination path, and an engine name. If the destination path does not exist, the function will attempt to create it.

Note that the export will result in the current data in memory written to the new destination directory. If the library is loaded into the workspace, the workspace version will be considered the most current version, and that is the version that will be exported.

Usage

```
lib_export(x, nm, directory_path, engine, filter = NULL, standard_eval = FALSE)
```

Arguments

<code>x</code>	The library to export.
<code>nm</code>	The variable name to hold the new library. The parameter will assume non-standard (unquoted) evaluation unless the <code>standard_eval</code> parameter is set to <code>TRUE</code> .
<code>directory_path</code>	The path to export the library to.
<code>engine</code>	The name of the engine to use for the exported data. The engine name corresponds to the standard file extension of the data file type. Valid values are <code>'rds'</code> , <code>'Rdata'</code> , <code>'rda'</code> , <code>'sas7bdat'</code> , <code>'xpt'</code> , <code>'xls'</code> , <code>'xlsx'</code> , <code>'dbf'</code> , <code>'csv'</code> , and <code>'parquet'</code> .
<code>filter</code>	A filter string to limit which datasets are exported. The filter parameter accepts wildcards.
<code>standard_eval</code>	A <code>TRUE</code> or <code>FALSE</code> value which indicates whether to use standard (quoted) or non-standard (unquoted) evaluation on the <code>nm</code> parameter. Default is <code>FALSE</code> . Use this parameter if you want to pass the target library name in a variable.

Value

The newly exported library.

See Also

Other lib: `is.lib()`, `lib_add()`, `lib_copy()`, `lib_delete()`, `lib_info()`, `lib_load()`, `lib_path()`, `lib_remove()`, `lib_replace()`, `lib_size()`, `lib_sync()`, `lib_unload()`, `lib_write()`, `libname()`, `print.lib()`

Examples

```
# Create temp directory
tmp <- tempdir()

# Create library
libname(dat1, tmp)

# Add dat to library
lib_add(dat1, mtcars, iris)

# Export dat1 to dat2
lib_export(dat1, dat2, file.path(tmp, "export"), "rdata")
# library 'dat2': 2 items
# - attributes: rdata not loaded
# - path: C:\Users\User\AppData\Local\Temp\Rtmp0Sq3kt/export
# - items:
#   Name Extension Rows Cols  Size      LastModified
# 1 mtcars      rdata   32   11 8.1 Kb 2022-06-23 00:10:52
# 2  iris       rdata  150    5 8.1 Kb 2022-06-23 00:10:52

# Clean up
lib_delete(dat1)
lib_delete(dat2)
```

`lib_info`*Get Information about a Data Library*

Description

The `lib_info` function returns a data frame of information about each item in the data library. That information includes the item name, file extension, number of rows, number of columns, size in bytes, and the last modified date.

Usage

```
lib_info(x)
```

Arguments

`x` The data library.

Value

A data frame of information about the library.

See Also

Other lib: `is.lib()`, `lib_add()`, `lib_copy()`, `lib_delete()`, `lib_export()`, `lib_load()`, `lib_path()`, `lib_remove()`, `lib_replace()`, `lib_size()`, `lib_sync()`, `lib_unload()`, `lib_write()`, `libname()`, `print.lib()`

Examples

```
# Create temp directory
tmp <- tempdir()

# Create data library
libname(dat, tmp)

# Add data to library
lib_add(dat, trees, rock, beaver1)

# Get library information
info <- lib_info(dat)

# Examine info
info
#      Name Extension Rows Cols  Size      LastModified
# 1 beaver1      rds  114   4 5.3 Kb 2020-11-05 21:27:57
# 2  rocks      rds   48   4 3.1 Kb 2020-11-05 21:27:56
# 3  trees      rds   31   3 2.4 Kb 2020-11-05 21:27:56

# Clean up
lib_delete(dat)
```

lib_load

Load a Library into the Workspace

Description

The `lib_load` function loads a data library into an environment. The environment used is associated with the library at the time it is created with the `libname` function. When the `lib_load` function is called, the data frames/tibbles will be loaded with `<library>.<data set>` syntax. Loading the data frames into the environment makes them easy to access and use in your program.

Note that the `lib_load` function is optional, and calling the function is not needed to access data in the `libname`. You may also access data directly from the `libname` using the dollar sign (`$`) syntax.

Usage

```
lib_load(x, filter = NULL)
```

Arguments

x	The data library to load.
filter	One or more quoted strings to use as filters for the data names to load into the workspace. For more than one filter string, pass them as a vector of strings. The filter string can be a full or partial name. If using a partial name, use a wild-card character (*) to identify the missing portion. The match will be case-insensitive.

Value

The loaded data library.

See Also

[lib_unload](#) to unload the library.

Other lib: [is.lib\(\)](#), [lib_add\(\)](#), [lib_copy\(\)](#), [lib_delete\(\)](#), [lib_export\(\)](#), [lib_info\(\)](#), [lib_path\(\)](#), [lib_remove\(\)](#), [lib_replace\(\)](#), [lib_size\(\)](#), [lib_sync\(\)](#), [lib_unload\(\)](#), [lib_write\(\)](#), [libname\(\)](#), [print.lib\(\)](#)

Examples

```
# Create temp directory
tmp <- tempdir()

# Save some data to temp directory for illustration purposes
saveRDS(iris, file.path(tmp, "iris.rds"))
saveRDS(ToothGrowth, file.path(tmp, "ToothGrowth.rds"))
saveRDS(PlantGrowth, file.path(tmp, "PlantGrowth.rds"))

# Create library
libname(dat, tmp)

# Load library into workspace
lib_load(dat)

# Examine workspace
ls()
# [1] "dat" "dat.iris" "dat.PlantGrowth" "dat.ToothGrowth" "tmp"

# Use some data
summary(dat.PlantGrowth)
summary(dat.ToothGrowth)

# Unload library
lib_unload(dat)

# Examine workspace again
ls()
# [1] "dat" "tmp"

# Clean up
lib_delete(dat)
```

lib_path	<i>Get the Path for a Data Library</i>
----------	--

Description

The `lib_path` function returns the current path of the the library as a string.

Usage

```
lib_path(x)
```

Arguments

`x` The data library.

Value

The path of the data library as a single string.

See Also

Other lib: [is.lib\(\)](#), [lib_add\(\)](#), [lib_copy\(\)](#), [lib_delete\(\)](#), [lib_export\(\)](#), [lib_info\(\)](#), [lib_load\(\)](#), [lib_remove\(\)](#), [lib_replace\(\)](#), [lib_size\(\)](#), [lib_sync\(\)](#), [lib_unload\(\)](#), [lib_write\(\)](#), [libname\(\)](#), [print.lib\(\)](#)

Examples

```
# Create temp directory
tmp <- tempdir()

# Create library
libname(dat, tmp)

# Examine library path
lib_path(dat)
# [1] "C:\Users\User\AppData\Local\Temp\RtmpCSJ6Gc"

# Clean up
lib_delete(dat)
```

lib_remove	<i>Remove Data from a Data Library</i>
------------	--

Description

The `lib_remove` function removes an item from the data library, and deletes the source file for that data. If the library is loaded, it will also remove that item from the workspace environment.

Usage

```
lib_remove(x, name)
```

Arguments

x	The data library.
name	The quoted name of the item to remove from the data library. For more than one name, pass a vector of quoted names.

Value

The library with the requested item removed.

See Also

Other lib: [is.lib\(\)](#), [lib_add\(\)](#), [lib_copy\(\)](#), [lib_delete\(\)](#), [lib_export\(\)](#), [lib_info\(\)](#), [lib_load\(\)](#), [lib_path\(\)](#), [lib_replace\(\)](#), [lib_size\(\)](#), [lib_sync\(\)](#), [lib_unload\(\)](#), [lib_write\(\)](#), [libname\(\)](#), [print.lib\(\)](#)

Examples

```
# Create temp directory
tmp <- tempdir()

# Create library
libname(dat, tmp)

# Add data to the library
lib_add(dat, mtcars, beaver1, iris)
# library 'dat': 3 items
# - attributes: not loaded
# - path: C:\Users\User\AppData\Local\Temp\RtmpCSJ6Gc
# - items:
#   Name Extension Rows Cols Size LastModified
# 1 mtcars rds 32 11 7.5 Kb 2020-11-05 19:32:00
# 2 beaver1 rds 114 4 5.1 Kb 2020-11-05 19:32:04
# 3 iris rds 150 5 7.5 Kb 2020-11-05 19:32:08

# Remove items from the library
lib_remove(dat, c("beaver1", "iris"))
```

```
# library 'dat': 1 items
# - attributes: not loaded
# - path: C:\Users\User\AppData\Local\Temp\RtmpCSJ6Gc
# - items:
#   Name Extension Rows Cols  Size      LastModified
# 1 mtcars      rds   32   11 7.5 Kb 2020-11-05 19:32:40

# Clean up
lib_delete(dat)
```

lib_replace

Replace Data in a Data Library

Description

The `lib_replace` function replaces a data frame in an existing data library. The function will replace the data in the library list, the data in the workspace (if loaded), and immediately write the new data to the library directory location. The data will be written in the file format associated with the library engine.

Usage

```
lib_replace(x, ..., name = NULL)
```

Arguments

<code>x</code>	The library to replace data in.
<code>...</code>	The data frame(s) to replace. If you wish to replace more than one data set, separate with commas.
<code>name</code>	The reference name to use for the data. By default, the name will be the variable name. To assign a name different from the variable name, assign a quoted name to this parameter. If more than one data set is being replaced, assign a vector of quoted names.

See Also

Other lib: `is.lib()`, `lib_add()`, `lib_copy()`, `lib_delete()`, `lib_export()`, `lib_info()`, `lib_load()`, `lib_path()`, `lib_remove()`, `lib_size()`, `lib_sync()`, `lib_unload()`, `lib_write()`, `libname()`, `print.lib()`

Examples

```
#' # Create temp directory
tmp <- tempdir()

# Create library
libname(dat, tmp)
```

```
# Add data to the library
lib_add(dat, mtcars)
# library 'dat': 3 items
# - attributes: not loaded
# - path: C:\Users\User\AppData\Local\Temp\RtmpCSJ6Gc
# - items:
#   Name Extension Rows Cols  Size      LastModified
# 1 mtcars      rds   32   11 7.5 Kb 2020-11-05 19:32:00

# Replace data with a subset
lib_replace(dat, mtcars[1:10, 1:5], name = "mtcars")
# library 'dat': 3 items
# - attributes: not loaded
# - path: C:\Users\User\AppData\Local\Temp\RtmpCSJ6Gc
# - items:
#   Name Extension Rows Cols  Size      LastModified
# 1 mtcars      rds   10   5 7.5 Kb 2020-11-05 19:33:00

# Clean up
lib_delete(dat)
```

lib_size

Get the Size of a Data Library

Description

The `lib_size` function returns the number of bytes used by the data library, as stored on disk.

Usage

```
lib_size(x)
```

Arguments

`x` The data library.

Value

The size of the data library in bytes as stored on the file system.

See Also

Other lib: [is.lib\(\)](#), [lib_add\(\)](#), [lib_copy\(\)](#), [lib_delete\(\)](#), [lib_export\(\)](#), [lib_info\(\)](#), [lib_load\(\)](#), [lib_path\(\)](#), [lib_remove\(\)](#), [lib_replace\(\)](#), [lib_sync\(\)](#), [lib_unload\(\)](#), [lib_write\(\)](#), [libname\(\)](#), [print.lib\(\)](#)

Examples

```
# Create temp directory
tmp <- tempdir()

# Create library
libname(dat, tmp)

# Add some data to library
lib_add(dat, mtcars)
lib_add(dat, iris)

# Check size of library
lib_size(dat)
# [1] 9757

# Clean up
lib_delete(dat)
```

lib_sync

Synchronize Loaded Library

Description

The `lib_sync` function synchronizes the data loaded into the working environment with the data stored in the library list. Synchronization is necessary only for libraries that have been loaded into the working environment. The function copies data from the working environment to the library list, overwriting any data in the list. The function is useful when you want to update the library list, but are not yet ready to unload the data from working memory.

Note that the `lib_sync` function does not write any data to disk. Also note that the `lib_sync` function will not automatically remove any variables from the library list that have been removed from the workspace. To remove items from the library list, use the `lib_remove` function. To write data to disk, use the `lib_write` function.

Usage

```
lib_sync(x, name = NULL)
```

Arguments

`x` The data library to synchronize.

`name` The name of the library to sync if not the variable name. Used internally.

Value

The synchronized data library.

See Also

Other lib: [is.lib\(\)](#), [lib_add\(\)](#), [lib_copy\(\)](#), [lib_delete\(\)](#), [lib_export\(\)](#), [lib_info\(\)](#), [lib_load\(\)](#), [lib_path\(\)](#), [lib_remove\(\)](#), [lib_replace\(\)](#), [lib_size\(\)](#), [lib_unload\(\)](#), [lib_write\(\)](#), [libname\(\)](#), [print.lib\(\)](#)

Examples

```
# Create temp directory
tmp <- tempdir()

# Create library
libname(dat, tmp)
# library 'dat': 0 items
# - attributes: not loaded
# - path: C:\Users\User\AppData\Local\Temp\RtmpCSJ6Gc
# NULL

# Load the library
lib_load(dat)

# Add data to the workspace
dat.mtcars <- mtcars
dat.beaver1 <- beaver1
dat.iris <- iris

# Sync the library
lib_sync(dat)
# library 'dat': 3 items
# - attributes: loaded
# - path: C:\Users\User\AppData\Local\Temp\RtmpCSJ6Gc
# - items:
#   Name Extension Rows Cols Size LastModified
# 1 beaver1      NA  114   4 4.6 Kb      <NA>
# 2 iris         NA  150   5 7.1 Kb      <NA>
# 3 mtcars       NA   32  11  7 Kb      <NA>

# Clean up
lib_delete(dat)
```

lib_unload*Unload a Library from the Workspace*

Description

The `lib_unload` function unloads a data library from the workspace environment. The unload function does not delete the data or remove the library. It simply removes the data frames from working memory. By default, the `lib_unload` function will also synchronize the data in working memory with the data stored in the library list, as these two instances can become out of sync if you change the data in working memory.

Usage

```
lib_unload(x, sync = TRUE, name = NULL)
```

Arguments

x	The data library to unload.
sync	Whether to sync the workspace with the library list before it is unloaded. Default is TRUE. If you want to unload the workspace without saving the workspace data, set this parameter to FALSE.
name	The name of the library to unload, if the name is different than the variable name. Used internally.

Value

The unloaded data library.

See Also

[lib_load](#) to load the library.

Other lib: [is.lib\(\)](#), [lib_add\(\)](#), [lib_copy\(\)](#), [lib_delete\(\)](#), [lib_export\(\)](#), [lib_info\(\)](#), [lib_load\(\)](#), [lib_path\(\)](#), [lib_remove\(\)](#), [lib_replace\(\)](#), [lib_size\(\)](#), [lib_sync\(\)](#), [lib_write\(\)](#), [libname\(\)](#), [print.lib\(\)](#)

Examples

```
# Create temp directory
tmp <- tempdir()

# Create library
libname(dat, tmp)

# Add data to library
lib_add(dat, iris, ToothGrowth, PlantGrowth)

# Load library into workspace
lib_load(dat)

# Examine workspace
ls()
# [1] "dat" "dat.iris" "dat.PlantGrowth" "dat.ToothGrowth" "tmp"

# Use some data
summary(dat.PlantGrowth)
summary(dat.ToothGrowth)

# Unload library
lib_unload(dat)

# Examine workspace again
ls()
```

```
# [1] "dat" "tmp"

# Clean up

lib_write*Write a Data Library to the File System*

Description

The `lib_write` function writes the data library to the file system. The library will be written to the directory for which it was defined, and each data frame will be written in the format associated with the library data engine. See the [libname](#) function for further elaboration on the types of engines available, and the assumptions/limitations of each.

By default, the `lib_write` function will not write data that has not changed. Prior to writing a file, `lib_write` will compare the data in memory to the data on disk. If there are differences in the data, the function will overwrite the version on disk. To override the default behavior, use the `force` option to force `lib_write` to write every data file to disk.

Note that writing `sas7bdat` files to disk is not supported.

Usage

```
lib_write(x, force = FALSE)
```

Arguments

<code>x</code>	The data library to write.
<code>force</code>	Force writing each data file to disk, even if it has not changed.

Value

The saved data library.

See Also

Other lib: [is.lib\(\)](#), [lib_add\(\)](#), [lib_copy\(\)](#), [lib_delete\(\)](#), [lib_export\(\)](#), [lib_info\(\)](#), [lib_load\(\)](#), [lib_path\(\)](#), [lib_remove\(\)](#), [lib_replace\(\)](#), [lib_size\(\)](#), [lib_sync\(\)](#), [lib_unload\(\)](#), [libname\(\)](#), [print.lib\(\)](#)

Examples

```
# Create temp directory
tmp <- tempdir()

# Create library
libname(dat, tmp)
## library 'dat': 0 items
# - attributes: rds not loaded
```

```

# - path: C:\Users\User\AppData\Local\Temp\RtmpCSJ6Gc
# NULL

# Load the empty library
lib_load(dat)

# Add data to the library
dat.mtcars <- mtcars
dat.beaver1 <- beaver1
dat.iris <- iris

# Unload the library
lib_unload(dat)
# library 'dat': 3 items
# - attributes: rds not loaded
# - path: C:\Users\User\AppData\Local\Temp\RtmpCSJ6Gc
# - items:
#      Name Extension Rows Cols  Size LastModified
# 1 beaver1      NA  114   4 4.6 Kb      <NA>

# Clean up
lib_delete(dat)

```

output

Outputs an observation from a datastep

Description

The output function will output an observation from a datastep. The function takes no parameters. To use the function, simply call it on the rows you want to output. Typically it is called within a conditional. The output function is interesting in that you can output multiple rows for the same input observation.

Usage

```
output()
```

Value

Observation is marked with a output flag. No return value.

See Also

Other datastep: [\[.dsarray\(\)\]](#), [datastep\(\)](#), [delete\(\)](#), [dsarray\(\)](#), [dsattr\(\)](#), [length.dsarray\(\)](#)

Examples

```
#' # Example 1: Output all cars that are 4 cylinder
df <- datastep(mtcars,
               keep = c("mpg", "cyl", "disp"), {

  if (cyl == 4)
    output()

})

df
#   mpg cyl  disp
# 1  22.8  4 108.0
# 2  24.4  4 146.7
# 3  22.8  4 140.8
# 4  32.4  4  78.7
# 5  30.4  4  75.7
# 6  33.9  4  71.1
# 7  21.5  4 120.1
# 8  27.3  4  79.0
# 9  26.0  4 120.3
# 10 30.4  4  95.1
# 11 21.4  4 121.0

# Example 2: Output two rows for each 6 cylinder car

# Prepare sample data
dat <- data.frame(name = rownames(mtcars), mtcars, stringsAsFactors = FALSE)

# Perform datastep
df <- datastep(dat,
               keep = c("name", "mpg", "cyl", "disp", "seq"), {

  if (cyl == 6) {
    seq <- 1
    output()
    seq <- 2
    output()
  }

})

df
#           name  mpg cyl  disp seq
```

```

```
print.lib
```

```
Print a data library
```

Description

A class-specific instance of the `print` function for data libraries. The function prints the library in a summary manner. Use `verbose = TRUE` to print the library as a list.

Usage

```
## S3 method for class 'lib'
print(x, ..., verbose = FALSE)
```

Arguments

x	The library to print.
...	Any follow-on parameters.
verbose	Whether or not to print the library in verbose style. By default, the parameter is FALSE, meaning to print in summary style.

Value

The object, invisibly.

See Also

print.specs

Print import specifications

Description

A function to print the import specification collection.

Usage

```
## S3 method for class 'specs'
print(x, ..., verbose = FALSE)
```

Arguments

`x` The specifications to print.

`...` Any follow-on parameters to the print function.

`verbose` Whether or not to print the specifications in verbose style. By default, the parameter is `FALSE`, meaning to print in summary style.

Value

The specification object, invisibly.

See Also

Other specs: [import_spec\(\)](#), [read.specs\(\)](#), [specs\(\)](#), [write.specs\(\)](#)

read.specs	<i>Read import specs from the file system</i>
------------	---

Description

A function to read import specifications from the file system. The function accepts a full or relative path to the spec file, and returns the specs as an object. If the `file_path` parameter is passed as a directory name, the function will search for a file with a `'.specs'` extension and read it.

Usage

```
read.specs(file_path = getwd())
```

Arguments

`file_path` The full or relative path to the file system. Default is the current working directory. If the `file_path` is a file name that does not contain the `'.specs'` file extension, the function will add the extension. If the `file_path` contains a directory name, the function will search the directory for a file with an extension of `'.specs'`. If more than one file with an extension of `'.specs'` is found, the function will generate an error.

Value

The specifications object.

See Also

Other specs: [import_spec\(\)](#), [print.specs\(\)](#), [specs\(\)](#), [write.specs\(\)](#)

Description

A function to capture a set of import specifications for a directory of data files. These specs can be used on the [libname](#) function to correctly assign the data types for imported data files. The import engines will guess at the data types for any columns that are not explicitly defined in the import specifications. Import specifications are defined with the [import_spec](#) function. The import spec syntax is the same for all data engines.

Note that the `na` and `trim_ws` parameters on the `specs` function will be applied globally to all files in the library. These global settings can be overridden on the [import_spec](#) for any particular data file.

Also note that the `specs` collection is defined as an object so it can be stored and reused. See the [write.specs](#) and [read.specs](#) functions for additional information on saving specs.

Usage

```
specs(..., na = c("", "NA"), trim_ws = TRUE)
```

Arguments

<code>...</code>	Named input specs. The name should correspond to the file name, without the file extension. The spec is defined as an import_spec object. See the import_spec function for additional information on parameters for that object.
<code>na</code>	A vector of values to be treated as NA. For example, the vector <code>c(' ', ' ')</code> will cause empty strings and single blanks to be converted to NA values. For most file types, empty strings and the string 'NA' (<code>' ', 'NA'</code>) are considered NA. For SAS® datasets and transport files, a single blank and a single dot <code>c(" ", ".")</code> are considered NA. The value of the <code>na</code> parameter on the <code>specs</code> function can be overridden by the <code>na</code> parameter on the import_spec function.
<code>trim_ws</code>	Whether or not to trim white space from the input data values. Valid values are TRUE, and FALSE. Default is TRUE. The value of the <code>trim_ws</code> parameter on the <code>specs</code> function can be overridden by the <code>trim_ws</code> parameter on the import_spec function.

Value

The import specifications object.

See Also

[libname](#) to create a data library, [dictionary](#) for generating a data dictionary, and [import_spec](#) for additional information on defining an import spec.

write.specs

Write import specs to the file system

Description

A function to write import specifications to the file system. The function accepts a specifications object and a full or relative path. The function returns the full file path. This function is useful so that you can define import specifications once, and reuse them in multiple programs or across multiple teams.

Usage

```
write.specs(x, dir_path = getwd(), file_name = NULL)
```

Arguments

x	A specifications object of class 'specs'.
dir_path	A full or relative path to save the specs. Default is the current working directory.
file_name	The file name to save to specs, without a file extension. The file extension will be added automatically. If no file name is supplied, the function will use the variable name as the file name.

Value

The full file path.

See Also

Other specs: [import_spec\(\)](#), [print.specs\(\)](#), [read.specs\(\)](#), [specs\(\)](#)

[.dsarray

Indexer for Data Step Array

Description

A custom indexer for the Datasstep Array. The indexer will return a value for all columns or a specified column. To access all columns, leave the indexer empty. Otherwise, specify the the column name(s) or number(s) to return data for. The indexer will always act upon the current row in the datasstep. For additional details, see the [dsarray](#) function.

Usage

```
## S3 method for class 'dsarray'
x[i = NULL]
```

Arguments

x	The dsarray object.
i	The index of the datasstep array item to return a value for. This index can be a column name or position in the array. It can also be a vector of column names or positions. If no index is supplied, a vector of all array values will be returned.

Value

The value of the specified column for the current row in the datasstep. If no index is supplied, a vector of all column values will be returned.

See Also
