Package 'DescToolsAddIns'

January 20, 2025

Type Package					
itle Interactive Functions to be Used as Shortcuts in 'RStudio'					
Version 1.12					
Date 2024-10-30					
Description 'RStudio' as of recently offers the option to define addins and assign shortcuts to them. This package contains addins for a few most frequently used functions in a data scentist's (at least mine) daily work (like str(), example(), plot(), head(), view(), Desc()). Most of these functions will use the current selection in the editor window and send the specific command to the console while instantly executing it. Assigning shortcuts to these addins will save you quite a few keystrokes.					
Depends base, stats, R ($>= 3.5.0$)					
Imports DescTools (>= 0.99.30), rstudioapi (>= 0.1), manipulate, writexl, foreign					
<pre>URL https://github.com/AndriSignorell/DescToolsAddIns/</pre>

Arrow

Insert an Arrow Into a Plot

Description

Places an arrow into a plot. Two additional arrow heads are implemented.

Usage

```
Arrow(x0, y0, x1, y1, col = par("bg"), border = par("fg"), head = 1, cex = 1, lwd = 1, lty = 1)
```

Arguments

x0, y0	coordinates of points from which to draw.
x1, y1	coordinates of points to which to draw. At least one must the supplied.
col	the color of the line and background color of the arrow head.
border	color of the arrow head.
head	type of head, can be one out of 1:3.
cex	extension factor for the arrow head.
lwd	line width
lty	line type

Value

Nothing returned

ColorDlg 3

Examples

```
library(DescTools)
Canvas()
Arrow(1, 1, 0, 0)
```

ColorDlg

Display Color Dialog to Choose a Color

Description

Choose a color by means of the system's color dialog. Nice for looking up RGB-values of any color.

Usage

ColorDlg()

Value

RGB value of the selected color

Author(s)

Andri Signorell <andri@signorell.net>

See Also

ColPicker

ColPicker

Plot All Named R Colors

Description

ColPicker() plots the R-colors in a dense manner and allows to collect colors by using a locator. This can be helpful when some colors should be put together to a palette.

Usage

4 dir.choose

Arguments

locator	logical, defines if the colors can be selected by mouseclick. Default is TRUE.
ord	the order of the colors, can be either defined by hsv-value or by the R internal color-number. Default is the latter.
label	label for the colors, can be the colorname (text), the hex-code ($\#RRGGBB$) or the decimal RGB-number
mdim	the dimension of the color matrix. Default is 38 rows and 12 columns.
newwin	logical, defining if a new graphic device should be used. Default is FALSE.

Details

The function plots all the colors but leaves out the grey scales grey() and gray().

Author(s)

Andri Signorell <andri@signorell.net>

See Also

```
par, colors, PlotPch
```

Examples

```
ColPicker(locator=FALSE, ord="hsv")
ColPicker(locator=FALSE, label="hex")
```

dir.choose

Choose a Folder Interactively

Description

Choose a directory interactively.

Usage

```
dir.choose(default = "", caption = "Select directory")
```

Arguments

default which directory to show initially.
caption the caption on the selection dialog

Value

A length-one character vector, character NA if 'Cancel' was selected.

FileImportDlg 5

Author(s)

Andri Signorell <andri@signorell.net>

See Also

```
file.choose
```

Examples

```
## Not run:
dir.choose(getwd(), "Choose a suitable folder")
## End(Not run)
```

FileImportDlg

Import File In Foreign Format

Description

Import a file in SPSS, Stata, SAS, Minitab or Systat format interactively.

Usage

```
FileImportDlg(auto_type = TRUE, env = .GlobalEnv)
```

Arguments

auto_type determines if the type dialog should be displayed. Default is FALSE, so that if the file extensions are ".sav", "dta" the appropriate dialog will be called directly.

env environment in which the dataset should be created.

Details

The imported file will be assigned to the given variablename.

Author(s)

Andri Signorell <andri@signorell.net>

See Also

```
read.dta(), read.spss(), read.systat(), read.ssd()
```

6 FileOpenDlg

FileOpenDlg

Get the Path of a Data File to Be Opened

Description

Handling of pathnames is tedious in Windows because of the backslashes, that prevent simple pasting of a copied path into the source code. FileOpenDlg() displays the FileOpen-Dialog for picking a file interactively. When done, backslashes in the returned path will be replaced by simple slashes as used in R path definitions. The edited path is returned.

Usage

```
FileOpenDlg(fmt = NULL)
```

Arguments

fmt

the format, in which the filename parts should be returned. This can be defined quite flexible containing the elements path, filename and ext (file extension) enclosed by %.

Default is path/filename.ext and coded as "%path%%filename%.%ext%". See examples for additional alternative definitions.

Details

There are 2 predefined formats that can be addressed with fmt = 1 resp. fmt = 2. 1 will return the path enclosed by a typical read.table(...) command, 2 will do the same with load(...).

Value

character string containing the path (also present in the clipboard)

Author(s)

Andri Signorell <andri@signorell.net>

See Also

```
file.choose
```

Examples

```
## Not run:
# choose a file
fn <- FileOpenDlg()
print(gettextf("You chose the file: %s ", fn))

# the path and filename can as well be nested in a command,
# done here to build a read.table command that can be well inserted into the code:
FileOpenDlg(fmt="d.%fname% <- read.table(file = \"%path%\%fname%.%fxt%\",</pre>
```

ModelDlg 7

```
header = TRUE, sep = \";\", na.strings = c(\"NA\",\"NULL\"), strip.white = TRUE)")
# go to your editor and paste...
## End(Not run)
```

ModelDlg

Compose Model Formula

Description

ModelDlg() allows to compose model formulas based on the variablenames of a data.frame. The available variables can be filtered and sorted, which is helpful to keep the overview. Additional orientation is provided by the comments with which variables can be assigned. (See Label()). The labels will be displayed below the variable list.

The model dialog can also be used to edit an already existing formula. Simply select the model formula (including the data argument) and start the dialog.

Usage

```
ModelDlg(x, ...)
```

Arguments

x the data frame containing the variables for the model.

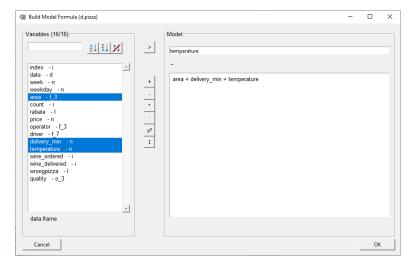

... further arguments to be passed to the default function.

Details

In the model dialog, the variablenames (extended with their class) of the selected data.frame are listed on the right, from where they can be inserted in the model box by clicking on a button between the two boxes. Clicking on the + button will use + to concatenate the variablenames. The same applies analogously to * and :. x^2 inserts the chunk poly(<varname>, 2), the grade of the polynom can easily be changed in the formula edit field afterwards.

Any criteria for the variablename can be entered in the filterbox. The filter will be dynamically applied to the list. In order to get rid of the filter just empty the filterbox.

8 Operating MS Word

After clicking on ok, the formula temperature ~ area + driver + delivery_min, data=d.pizza will be inserted on the cursor position.

An already constructed formula can also be provided to the function. The model dialog will separate the single parts and populate the according textboxes.

Value

the model formula

Author(s)

Andri Signorell <andri@signorell.net>

See Also

formula

Examples

```
## Not run:
ModelDlg(d.pizza)
## End(Not run)
```

Operating MS Word

Operating MS Word

Description

Controlling MS Word with RStudio has many convenient advantages. We can quickly create some reports on the fly and also use bookmarks to create dynamically updatable report chunks such as tables or graphics. Here we implement a set of functions to handle bookmarks in MS Word.

Operating MS Word 9

Usage

```
ToWrd()
ToWrdWithBookmark()
WrdBookmarks()
CreateBookmark()
SelectBookmark()
UpdateBookmark()
DeleteBookmark()
RenameBookmark(name, newname, wrd = DescToolsOptions("lastWord"))
RecreateBookmarkChunk()
```

Arguments

name the name of the bookmark.

newname the new name of the bookmark.

wrd the pointer to a word instance. Can be a new one, created by GetNewWrd() or

an existing one, created by GetCurrWrd(). Default is the last created pointer

stored in DescToolsOptions("lastWord").

Details

WrdBookmarks() returns a data frame with all bookmarks in the current document (given by a handle created with GetCurrWrd() or GetNewWrd() and stored in DescToolsOptions("lastWord")), containing the bookmark's name, its id and type ("text", "plot", "other"), as well as the page number in the document where it starts.

ToWrd() directly sends the evaluation of the selected object in the source panel to the current Word instance. The function is generic and acts in dependency on the selected object. So far there are interfaces for characters, tables, models. Note that the inserted text is no longer updateable; as soon as it is inserted in the Word document the connection to it is lost.

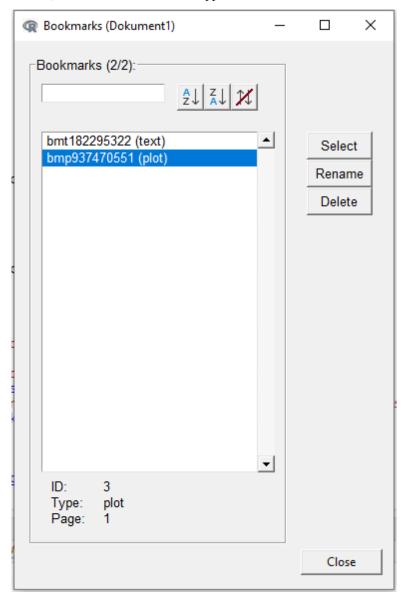

ToWrdWithBookmark() inserts the object in the Word document and defines a bookmark that covers the whole range of the inserted object (including tables or graphics). Then the selected command chunk in the Rstudio source pane is enclosed in brackets and the name of the new defined bookmark is therein inserted as meta tag. If the R-code is later changed, the output in Word can simply be refreshed by selecting the code chunk in RStudio (including the meta tag) and click on the menu UpdateBookmark() (of course it's convenient to have a shortcut defined for that).

CreateBookmark() creates a bookmark at the current cursor position in a in an open Word document, using the currently selected text in RStudio as name. SelectBookmark(), DeleteBookmark() behave analogously.

10 Operating MS Word

RecreateBookmarkChunk() recreates the selected chunks in RStudio by inserting a bookmark if not existing and updating it with the result.

With the BookmarkDlg() there's an interactive support for handling bookmarks. Found bookmarks are presented in a sortable and filterable listbox. Selecting, deleting and renaming (not yet implemented) the selected bookmark is supported.

PlotPch 11

Description

The function PlotPar() plots the typically used parameters and their values.

Usage

```
PlotPar()
PlotPch(col = NULL, bg = NULL, newwin = FALSE)
PlotMar()
```

Arguments

col the default plotting color for PlotPch. Defaults to hred.

bg The color to be used for the background of the plot symbols. Default is hecru.

newwin logical, defining if a new graphic device should be used. Default is FALSE.

Details

```
PlotPch() will display the plot characters as defined by pch in all plots in a dialog. PlotMar() plots the margins.
```

Author(s)

Andri Signorell <andri@signorell.net>

See Also

```
par, colors
```

Examples

```
PlotPar()
PlotPch()
```

RStudio AddIns

Some Functions to be Used as Shortcuts in 'RStudio'

Description

A simply great new feature in RStudio is the option to define add-ins and bind shortcuts to them. This package includes add-ins for some of the most frequently used functions in a data scientist's (at least mine) daily work (like str(), example(), plot(), head(), view(), Desc()).

Most of these functions use the current selection in RStudios source panel and send the specific command to the console where it is executed immediately. Assigning shortcuts to these add-ins saves you tons of keystrokes and brings a breeze of liberating and brake-releasing GUI-interaction into your R-life.

Usage

```
NewObject()
FileOpen()
FileBrowserOpen()
FileSaveAs()
GetExcelRange(env = .GlobalEnv, header = FALSE, echo = TRUE)
GetExcelRangeH(env = .GlobalEnv)
GetExcelTable(env = .GlobalEnv)
XLView()
IntView()
Edit()
FlushToSource()
Select()
Str()
Str1()
Abstract()
Head()
Some()
Summary()
Cat()
Desc()
Example()
Info()
Unclass()
Plot()
PlotD()
SetArrow()
InspectPnt()
Enquote()
```

EnquoteS()
RemoveDuplicates()
SortAsc()
SortDesc()
Shuffle()
EvalEnquote()
FlipBackSlash()

Arguments

env Environment for GetExcelRange to write the data. GlobalEnv is default. header logical determining if the import from XL should use a header or not

echo should the function return an echo

Details

The following add-ins are available:

• NewObject:

starts the good old internal editor and allows to enter values. In dependence of the initial selection in the code panel different objects will be returned. If the selection was m the code for a matrix will be created, if the selection is d then the code for a data.frame will be returned and a c will be interpreted as vector. Default is m. Note that column names can be defined within the editor, but not rownames (don't ask me why ...).

• FileOpen:

get the path of a file to open and insert in code. (See also: Select())

FileBrowserOpen:

get a selected path and opens the systems filebrowser with the according directory.

• FileImport:

display the import file dialog for importing SAS, SPSS, Stata, Systat and MiniTab files. (See FileImportDlg())

• FileSaveAs:

display a file dialog, get the desired path and filename and save the selected object in the given place. Several file types are supported csv/xlsx for data.frames, text/binary for other objects.

Get XI Range

run DescTools command XLGetRange() by taking the current selection as name for the imported data and replace the current selection by the used code.

• GetXLTable:

run DescTools command XLGetRange() by taking the current 3-fold selection as data matrix, rownames and columnnames and replace the current selection by the structure code.

• XI View

view selected object in MS-Excel, which makes sense for data.frames.

• IntView:

view selected object with internal viewer (here again: only data.frames)

• Edit

run R-command fix() on the current selection. This is nice for editing data frames interactively.

• FlushToSource:

run dput on the current selection and replace the selection with the result.

• Select:

select or pick things interactively. This function as well evaluates the current selection. If the selection corresponds to pch a dialog for selecting point characters will be displayed. If it's col the ColPicker() dialog will be displayed. If it's any of path, fn, file the FileOpen() dialog will be displayed. In all other case the SelectVarDlg() on the current selection will be run. This can be used to select variablenames of a data. frame by mouse click or the levels of a factor (all depending on the class of the selected object). The variable names will be returned as string, enquoted and separated by a comma.

• Str. Str1:

run DescTools command Str() on the current selection, Str1() shows only the first level;

• Abstract:

run DescTools command Abstract() (a less technical description than str(), meant for using with data.frames) on the current selection

• Head:

run R-command head() on the current selection

Some

run DescTools command Some() on the current selection

• Summary:

run R-command summary() on the current selection

• Cat:

run R-command $cat(..., sep="\n")$ on the current selection

Desc

run DescTools command Desc() on the current selection

• Example:

run R-command example() on the current selection

• Info

print object properties of the currently selected object

• Unclass:

run R-command unclass() on the current selection

• Plot:

run plot() on the current selection

• PlotD:

run plot(Desc()) on the current selection

• SetArrow:

place an arrow in a plot and insert code into source file

• InspectPnt:

Lauch IdentifyA(\dots , poly=TRUE) with the current selection as argument and returns the selected points on the plot.

• BuildModel:

display dialog for building up a model formula interactively by point and click. (See ModelDlg())

• Enquote, EnquoteS:

split the selected text in the source panel using line breaks as separators, enquote the sections using either double or single quotation marks, and paste them separated by comma.

• RemoveDuplicates:

remove all the duplicates (by row) of the selected text.

• SortAsc, SortDesc, Shuffle: sorts the selected text by row in ascending, descending, resp. random order.

• EvalEnquote:

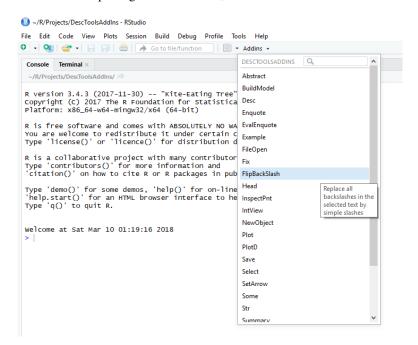

evaluates the selection before enquoting the parts and paste them separated by comma. This can be used to enquote factors.

• FlipBackSlash:

Handling backslashes in pathnames can be really annoying on Windows. This function replaces all backslashes in the selected text by simple slashes. In the first step all backlashes are replaced by slashes, in further applications of the function, flipflops are performed between slashes and backslashes. The option ReplaceDoubleSlash controls whether double slashes should be replaced by simple ones.

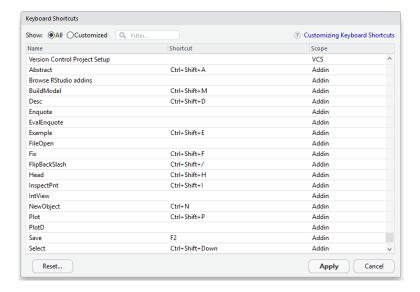

It's cool to set this command to the keyboard shortcut: Ctrl+Shift+/

As soon as the package is loaded once, the AddIns will be listed in RStudios AddIns listbox:

The keyboard shortcuts can then be assigned by clicking on the menu Tools | Modify Keyboard Shortcuts... and scroll down to the Addin scope:

SelectVarDlg

Author(s)

Andri Signorell <andri@signorell.net>

Examples

```
if (interactive()){
  Str()
}
```

SelectVarDlg

Select Elements of a Set by Click

Description

SelectVarDlg() is a GUI utility, which brings up a dialog and lets the user select elements (either variables of a data.frame or levels of a factor) by point and click in a listbox. The list of selected items is written to the clipboard so that the code can afterwards easily be pasted in the source file. This function is best used together with the package DescToolsAddIns, with which the functions can be assigned to a keystroke in RStudio.

Usage

```
SelectVarDlg(x, ...)
## Default S3 method:
SelectVarDlg(x, useIndex = FALSE, ...)
## S3 method for class 'factor'
```

SelectVarDlg 17

```
SelectVarDlg(x, ...)
## S3 method for class 'data.frame'
SelectVarDlg(x, ...)
```

Arguments

x the object containing the elements to be selected. x can be a data.frame, a factor

or any other vector.

useIndex defines, if the enquoted variablenames (default) or the index values should be

returned.

... further arguments to be passed to the default function.

Details

When working with big data.frames with many variables it is often tedious to build subsets by typing the columnnames. Here is where the function comes in offering a "point and click" approach for selecting the interesting columns. When x is a data.frame the columnnames are listed, when x is a factor the according levels are listed and in all other cases the list is filled with the unique elements of x.

SelectVarDlg() checks for an option "selkey" for defining the selection keywords, defined as a list of this structure:

```
file the keywords to be interpreted as a filename, defaults to c("fn", "file", "filename") the keywords to be interpreted as a directory name, defaults to c("path", "dir") col the keywords to be interpreted as a color, defaults to c("col", "color") pch the keywords to be interpreted as a point character, defaults to c("pch")
```

It can be set with

Value

A comma separated list with the selected values enquoted is returned invisibly as well as written to clipboard for easy inserting the text in an editor afterwards.

Author(s)

select.list
```

Xplore Xplore

Examples

```
## Not run:
SelectVarDlg(x = d.pizza$driver)
SelectVarDlg(x = d.pizza, useIndex=TRUE)

SelectVarDlg(d.pizza$driver)

x <- replicate(10, paste(sample(LETTERS, 5, replace = TRUE), collapse="""))
SelectVarDlg(x)

## End(Not run)</pre>
```

Xplore

Interactive Graphical Data Explorer

Description

Use RStudio's manipulator to explore a data.frame by dynamically creating xy-scatterplots, boxplots and others. Numerical descriptions can as well be produced on the fly.

Usage

```
Xplore(x)
```

Arguments

Х

the data.frame to be explored.

Details

This function helps to get rid of the afterwards superfluous R-code created while exploring a dataset.

Author(s)

Andri Signorell <andri@signorell.net>

Examples

```
## Not run:
Xplore(d.pizza)
## End(Not run)
