# Package 'MazamaRollUtils'

January 20, 2025

```
Type Package
Title Efficient Rolling Functions
Version 0.1.3
Date 2021-09-15
Author Jonathan Callahan [aut, cre],
     Hans Martin [aut]
Maintainer Jonathan Callahan < jonathan.s.callahan@gmail.com>
Description A suite of compiled functions calculating rolling mins, means,
     maxes and other statistics. This package is designed to meet the needs of
     data processing systems for environmental time series.

MazamaRollUtils-package

Mazama Science Rolling Utilities

# Description

A suite of utility functions for calculating rolling mins, means, maxes and other functions written with an efficient Rcpp/C++ backend.

## Author(s)

Jonathan Callahan, Hans Martin

example\_pm25

Example timeseries dataset

# Description

The example\_pm25\_data dataset provides example timeseries data for practicing and code examples. This data represents hourly air quality measurements.

This dataset was was generated on 2021-09-22 by running:

```
library(AirSensor)
example_pm25 <- example_sensor$data
names(example_pm25) <- c("datetime", "pm25")
save(example_pm25, file = "data/example_pm25.rda")</pre>
```

findOutliers 3

#### Usage

```
example_pm25
```

#### **Format**

A dataframe with columns "datetime" and "pm25".

findOutliers

Outlier Detection with a Rolling Hampel Filter

## **Description**

A wrapper for the roll\_hampel() function that counts outliers using either a user specified threshold value or a threshold value based on the statistics of the incoming data.

#### Usage

```
findOutliers(
   x,
   width = 25,
   thresholdMin = 7,
   selectivity = NA,
   fixedThreshold = TRUE
)
```

#### **Arguments**

x Numeric vector.

width Integer width of the rolling window.
thresholdMin Numeric threshold for outlier detection

selectivity Value between [0-1] used in determining outliers, or NA if fixedThreshold=TRUE.

fixedThreshold Logical specifying whether outlier detection uses selectivity (see Details).

## **Details**

The thresholdMin level is similar to a sigma value for normally distributed data. Hampel filter values above 6 indicate a data value that is extremely unlikely to be part of a normal distribution (~ 1/500 million) and therefore very likely to be an outlier. By choosing a relatively large value for thresholdMin we make it less likely that we will generate false positives. False positives can include high frequency environmental noise.

With the default setting of fixedThreshold = TRUE any value above the threshold is considered an outlier and the selectivity is ignored.

The selectivity is a value between 0 and 1 and is used to generate an appropriate threshold for outlier detection based on the statistics of the incoming data. A lower value for selectivity will

4 roll\_hampel

result in more outliers while a value closer to 1.0 will result in fewer. If fixedThreshold=TRUE, selectivity may have a value of NA.

When the user specifies fixedThreshold=FALSE, the thresholdMin and selectivity parameters work like squelch and volume on a CB radio: thresholdMin sets a noise threshold below which you don't want anything returned while selectivity adjusts the number of points defined as outliers by setting a new threshold defined by the maximum value of roll\_hampel multiplied by selectivity.

width, the window width, is a parameter that is passed to roll\_hampel().

#### Value

A vector of indices associated with outliers in the incoming data x.

#### Note

This function is copied from the **seismicRoll** package.

## See Also

```
roll_hampel
```

## **Examples**

```
# Noisy sinusoid with outliers
a <- jitter(sin(0.1*seq(1e4)),amount=0.2)
indices <- sample(seq(1e4),20)
a[indices] <- a[indices]*10

# Outlier detection should identify many of these altered indices
sort(indices)
o_indices <- findOutliers(a)
o_indices

plot(a)
points(o_indices, a[o_indices], pch = 16, cex = 0.8, col = 'red')
title("Outlier detection using a Hampel filter")</pre>
```

roll\_hampel

Roll Hampel

## **Description**

Apply a moving-window Hampel function to a numeric vector.

roll\_hampel 5

#### Usage

```
roll_hampel(
    x,
    width = 1L,
    by = 1L,
    align = c("center", "left", "right"),
    na.rm = FALSE
)
```

#### **Arguments**

X	Numeric vector.
width	Integer width of the rolling window.
by	Integer shift to use when sliding the window to the next location
align	Character position of the return value within the window. One of: "left"   "center"   "right".
na.rm	Logical specifying whether NA values should be removed before the calculations within each window.

#### **Details**

The Hampel filter is a robust outlier detector using Median Absolute Deviation (MAD).

For every index in the incoming vector x, a value is returned that is the Hampel funcion of all values in x that fall within a window of width width.

The align parameter determines the alignment of the return value within the window. Thus:

- align = -1 [\*----] will cause the returned vector to have width-1 NA values at the right end.
- align = 0 [---\*--] will cause the returned vector to have width/2 NA values at either end.
- align = 1 [----\*] will cause the returned vector to have width-1 NA values at the left end.

For large vectors, theby parameter can be used to force the window to jump ahead by indices for the next calculation. Indices that are skipped over will be assigned NA values so that the return vector still has the same length as the incoming vector. This can dramatically speed up calculations for high resolution time series data.

#### Value

Numeric vector of the same length as x.

```
library(MazamaRollUtils)  x <- c(0, 0, 0, 1, 1, 2, 2, 4, 6, 9, 0, 0, 0) \\ roll_hampel(x, 3)
```

6 roll\_MAD

roll\_MAD

## **Description**

Apply a moving-window Median Absolute Deviation function to a numeric vector.

Roll MAD

# Usage

```
roll_MAD(
    x,
    width = 1L,
    by = 1L,
    align = c("center", "left", "right"),
    na.rm = FALSE
)
```

#### **Arguments**

x	Numeric vector.
width	Integer width of the rolling window.
by	Integer shift to use when sliding the window to the next location
align	Character position of the return value within the window. One of: "left"   "center"   "right".
na.rm	Logical specifying whether NA values should be removed before the calculations within each window.

## **Details**

For every index in the incoming vector x, a value is returned that is the Median Absolute Deviation (MAD) of all values in x that fall within a window of width width.

The align parameter determines the alignment of the return value within the window. Thus:

- align = -1 [\*----] will cause the returned vector to have width-1 NA values at the right
- align = 0 [---\*--] will cause the returned vector to have width/2 NA values at either end.
- align = 1 [----\*] will cause the returned vector to have width-1 NA values at the left end.

For large vectors, theby parameter can be used to force the window to jump ahead by indices for the next calculation. Indices that are skipped over will be assigned NA values so that the return vector still has the same length as the incoming vector. This can dramatically speed up calculations for high resolution time series data.

#### Value

Numeric vector of the same length as x.

roll\_max 7

#### **Examples**

```
library(MazamaRollUtils)

# Wikipedia example
x <- c(0, 0, 0, 1, 1, 2, 2, 4, 6, 9, 0, 0, 0)
roll_MAD(x, 3)
roll_MAD(x, 5)
roll_MAD(x, 7)</pre>
```

roll\_max

Roll Max

# Description

Apply a moving-window maximum function to a numeric vector.

## Usage

```
roll_max(
    x,
    width = 1L,
    by = 1L,
    align = c("center", "left", "right"),
    na.rm = FALSE
)
```

# Arguments

X	Numeric vector.
width	Integer width of the rolling window.
by	Integer shift to use when sliding the window to the next location
align	Character position of the return value within the window. One of: "left"   "center"   "right".
na.rm	Logical specifying whether NA values should be removed before the calculations within each window.

#### **Details**

For every index in the incoming vector x, a value is returned that is the maximum of all values in x that fall within a window of width width.

The align parameter determines the alignment of the return value within the window. Thus:

- align = -1 [\*----] will cause the returned vector to have width-1 NA values at the right end.
- align = 0 [---\*--] will cause the returned vector to have width/2 NA values at either end.

8 roll\_mean

• align = 1 [-----\*] will cause the returned vector to have width-1 NA values at the left end.

For large vectors, theby parameter can be used to force the window to jump ahead by indices for the next calculation. Indices that are skipped over will be assigned NA values so that the return vector still has the same length as the incoming vector. This can dramatically speed up calculations for high resolution time series data.

#### Value

Numeric vector of the same length as x.

#### **Examples**

```
library(MazamaRollUtils)
# Example air quality time series
t <- example_pm25$datetime
x <- example_pm25$pm25
plot(t, x, pch = 16, cex = 0.5)
lines(t, roll_max(x, width = 12), col = 'red')
lines(t, roll_min(x, width = 12), col = 'deepskyblue')
title("12-hr Rolling Max and Min")
plot(t, x, pch = 16, cex = 0.5)
points(t, roll_max(x, width = 12, na.rm = TRUE),
       pch = 16, col = 'red')
points(t, roll_max(x, width = 12, na.rm = FALSE),
       pch = 16, col = adjustcolor('black', 0.4))
legend("topright", pch = c(1, 16),
       col = c("red", adjustcolor("black", 0.4)),
       legend = c("na.rm = TRUE", "na.rm = FALSE"))
title("12-hr Rolling max with/out na.rm")
```

roll\_mean

Roll Mean

# Description

Apply a moving-window mean function to a numeric vector.

# Usage

```
roll_mean(
    x,
    width = 1L,
    by = 1L,
    align = c("center", "left", "right"),
```

roll\_mean 9

```
na.rm = FALSE,
weights = NULL
)
```

#### **Arguments**

X	Numeric vector.
width	Integer width of the rolling window.
by	Integer shift by which the window is moved each iteration.
align	Character position of the return value within the window. One of: "left"   "center"   "right".
na.rm	Logical specifying whether NA values should be removed before the calculations within each window.
weights	Numeric vector of size width specifying each window index weight. If NULL, unit weights are used.

#### **Details**

For every index in the incoming vector x, a value is returned that is the mean of all values in x that fall within a window of width width.

The align parameter determines the alignment of the return value within the window. Thus:

- align = -1 [\*----] will cause the returned vector to have width-1 NA values at the right end.
- align = 0 [---\*--] will cause the returned vector to have width/2 NA values at either end.
- align = 1 [----\*] will cause the returned vector to have width-1 NA values at the left end.

For large vectors, theby parameter can be used to force the window to jump ahead by indices for the next calculation. Indices that are skipped over will be assigned NA values so that the return vector still has the same length as the incoming vector. This can dramatically speed up calculations for high resolution time series data.

The roll\_mean() function supports an additional weights argument that can be used to calculate a "weighted moving average" – a convolution of the incoming data with the *kernel* (weighting function) provided in weights.

#### Value

Numeric vector of the same length as x.

```
library(MazamaRollUtils)
# Example air quality time series
t <- example_pm25$datetime
x <- example_pm25$pm25
plot(t, x, pch = 16, cex = 0.5)</pre>
```

10 roll\_median

roll\_median

Roll Median

## **Description**

Apply a moving-window median function to a numeric vector.

## Usage

```
roll_median(
    x,
    width = 1L,
    by = 1L,
    align = c("center", "left", "right"),
    na.rm = FALSE
)
```

#### **Arguments**

Χ	Numeric vector.
width	Integer width of the rolling window.
by	Integer shift by which the window is moved each iteration.
align	Character position of the return value within the window. One of: "left"   "center"   "right".
na.rm	Logical specifying whether NA values should be removed before the calculations within each window.

#### **Details**

For every index in the incoming vector x, a value is returned that is the median of all values in x that fall within a window of width width.

The align parameter determines the alignment of the return value within the window. Thus:

- align = -1 [\*----] will cause the returned vector to have width-1 NA values at the right end.
- align = 0 [---\*--] will cause the returned vector to have width/2 NA values at either end.
- align = 1 [----\*] will cause the returned vector to have width-1 NA values at the left end.

For large vectors, theby parameter can be used to force the window to jump ahead by indices for the next calculation. Indices that are skipped over will be assigned NA values so that the return vector still has the same length as the incoming vector. This can dramatically speed up calculations for high resolution time series data.

roll\_min 11

## Value

Numeric vector of the same length as x.

## **Examples**

roll\_min

Roll Min

# Description

Apply a moving-window minimum function to a numeric vector.

# Usage

```
roll_min(
    x,
    width = 1L,
    by = 1L,
    align = c("center", "left", "right"),
    na.rm = FALSE
)
```

#### **Arguments**

X	Numeric vector.
width	Integer width of the rolling window.
by	Integer shift by which the window is moved each iteration.
align	Character position of the return value within the window. One of: "left"   "center"   "right".
na.rm	Logical specifying whether NA values should be removed before the calculations within each window.

12 roll\_prod

#### **Details**

For every index in the incoming vector x, a value is returned that is the minimum of all values in x that fall within a window of width width.

The align parameter determines the alignment of the return value within the window. Thus:

- align = -1 [\*----] will cause the returned vector to have width-1 NA values at the right end.
- align = 0 [---\*--] will cause the returned vector to have width/2 NA values at either end.
- align = 1 [-----\*] will cause the returned vector to have width-1 NA values at the left end.

For large vectors, theby parameter can be used to force the window to jump ahead by indices for the next calculation. Indices that are skipped over will be assigned NA values so that the return vector still has the same length as the incoming vector. This can dramatically speed up calculations for high resolution time series data.

#### Value

Numeric vector of the same length as x.

#### **Examples**

```
library(MazamaRollUtils)
# Example air quality time series
t <- example_pm25$datetime
x <- example_pm25$pm25
plot(t, x, pch = 16, cex = 0.5)
lines(t, roll_max(x, width = 12), col = 'red')
lines(t, roll_min(x, width = 12), col = 'deepskyblue')
title("12-hr Rolling Max and Min")
plot(t, x, pch = 16, cex = 0.5)
points(t, roll_min(x, width = 12, na.rm = TRUE),
       pch = 16, col = 'deepskyblue')
points(t, roll_min(x, width = 12, na.rm = FALSE),
       pch = 16, col = adjustcolor('black', 0.4))
legend("topright", pch = c(16, 16),
       col = c("deepskyblue", adjustcolor("black", 0.4)),
       legend = c("na.rm = TRUE", "na.rm = FALSE"))
title("12-hr Rolling min with/out na.rm")
```

roll\_prod

Roll Product

#### **Description**

Apply a moving-window product function to a numeric vector.

roll\_prod

#### Usage

```
roll_prod(
   x,
   width = 1L,
   by = 1L,
   align = c("center", "left", "right"),
   na.rm = FALSE
)
```

#### **Arguments**

X	Numeric vector.
width	Integer width of the rolling window.
by	Integer shift by which the window is moved each iteration.
align	Character position of the return value within the window. One of: "left"   "center"   "right".
na.rm	Logical specifying whether NA values should be removed before the calculations within each window.

#### **Details**

For every index in the incoming vector x, a value is returned that is the product of all values in x that fall within a window of width width.

The align parameter determines the alignment of the return value within the window. Thus:

- align = -1 [\*----] will cause the returned vector to have width-1 NA values at the right end.
- align = 0 [---\*--] will cause the returned vector to have width/2 NA values at either end.
- align = 1 [----\*] will cause the returned vector to have width-1 NA values at the left end.

For large vectors, theby parameter can be used to force the window to jump ahead by indices for the next calculation. Indices that are skipped over will be assigned NA values so that the return vector still has the same length as the incoming vector. This can dramatically speed up calculations for high resolution time series data.

#### Value

Numeric vector of the same length as x.

```
library(MazamaRollUtils)
# Example air quality time series
t <- example_pm25$datetime
x <- example_pm25$pm25
x[1:10]
roll_prod(x, width = 5)[1:10]</pre>
```

roll\_sd

ral	1	$\sim 4$
1 0 1	Τ_	_sa

Roll Standard Deviation

#### **Description**

Apply a moving-window standard deviation function to a numeric vector.

## Usage

```
roll_sd(x, width = 1L, by = 1L, align = c("center", "left", "right"))
```

## **Arguments**

X	Numeric vector.
width	Integer width of the rolling window.
by	Integer shift by which the window is moved each iteration.
align	Character position of the return value within the window. One of: "left"   "center"   "right".

#### **Details**

For every index in the incoming vector x, a value is returned that is the standard deviation of all values in x that fall within a window of width width.

The align parameter determines the alignment of the return value within the window. Thus:

- align = -1 [\*----] will cause the returned vector to have width-1 NA values at the right end.
- align = 0 [---\*--] will cause the returned vector to have width/2 NA values at either end.
- align = 1 [----\*] will cause the returned vector to have width-1 NA values at the left end.

For large vectors, theby parameter can be used to force the window to jump ahead by indices for the next calculation. Indices that are skipped over will be assigned NA values so that the return vector still has the same length as the incoming vector. This can dramatically speed up calculations for high resolution time series data.

#### Value

Numeric vector of the same length as x.

#### Note

No na.rm argument is provided as interpretation of the results is not at all clear.

roll\_sum

#### **Examples**

```
library(MazamaRollUtils)

# Example air quality time series
t <- example_pm25$datetime
x <- example_pm25$pm25

x[1:10]
roll_sd(x, width = 5)[1:10]</pre>
```

roll\_sum

Roll Sum

## **Description**

Apply a moving-window sum to a numeric vector.

# Usage

```
roll_sum(
    x,
    width = 1L,
    by = 1L,
    align = c("center", "left", "right"),
    na.rm = FALSE
)
```

#### **Arguments**

Х	Numeric vector.
width	Integer width of the rolling window.
by	Integer shift by which the window is moved each iteration.
align	Character position of the return value within the window. One of: "left"   "center"   "right".
na.rm	Logical specifying whether NA values should be removed before the calculations within each window.

#### **Details**

For every index in the incoming vector x, a value is returned that is the sum of all values in x that fall within a window of width width.

The align parameter determines the alignment of the return value within the window. Thus:

- align = -1 [\*----] will cause the returned vector to have width-1 NA values at the right end.
- align = 0 [---\*--] will cause the returned vector to have width/2 NA values at either end.

16 roll\_var

• align = 1 [-----\*] will cause the returned vector to have width-1 NA values at the left end.

For large vectors, theby parameter can be used to force the window to jump ahead by indices for the next calculation. Indices that are skipped over will be assigned NA values so that the return vector still has the same length as the incoming vector. This can dramatically speed up calculations for high resolution time series data.

## Value

Numeric vector of the same length as x.

# **Examples**

```
library(MazamaRollUtils)
# Example air quality time series
t <- example_pm25$datetime
x <- example_pm25$pm25
x[1:10]
roll_sum(x, width = 5)[1:10]</pre>
```

roll\_var

Roll Variance

## **Description**

Apply a moving-window variance function to a numeric vector.

## Usage

```
roll_var(x, width = 1L, by = 1L, align = c("center", "left", "right"))
```

## **Arguments**

x	Numeric vector.
width	Integer width of the rolling window.
by	Integer shift by which the window is moved each iteration.
align	Character position of the return value within the window. One of: "left"   "center"   "right".

roll\_var

#### **Details**

For every index in the incoming vector x, a value is returned that is the variance of all values in x that fall within a window of width width.

The align parameter determines the alignment of the return value within the window. Thus:

- align = -1 [\*----] will cause the returned vector to have width-1 NA values at the right end.
- align = 0 [---\*--] will cause the returned vector to have width/2 NA values at either end.
- align = 1 [-----\*] will cause the returned vector to have width-1 NA values at the left end.

For large vectors, theby parameter can be used to force the window to jump ahead by indices for the next calculation. Indices that are skipped over will be assigned NA values so that the return vector still has the same length as the incoming vector. This can dramatically speed up calculations for high resolution time series data.

#### Value

Numeric vector of the same length as x.

#### Note

No na.rm argument is provided as interpretation of the results is not at all clear.

```
library(MazamaRollUtils)

# Example air quality time series
t <- example_pm25$datetime
x <- example_pm25$pm25

x[1:10]
roll_var(x, width = 5)[1:10]</pre>
