

# Package ‘plasma’

April 28, 2024

**Title** Partial LeAst Squares for Multiomic Analysis

**Version** 1.1.3

**Date** 2024-04-26

**Description** Contains tools for supervised analyses of incomplete, overlapping multiomics datasets. Applies partial least squares in multiple steps to find models that predict survival outcomes. See Yamaguchi et al. (2023) <[doi:10.1101/2023.03.10.532096](https://doi.org/10.1101/2023.03.10.532096)>.

**Depends** R (>= 3.5.0)

**Imports** methods, stats, graphics, survival, pls, plsRcox, Polychrome (>= 1.5.0), viridisLite, beanplot, oompaBase

**Suggests** R.rsp, tidy, ClassDiscovery

**License** Apache License (== 2.0)

**LazyLoad** yes

**URL** <http://oompa.r-forge.r-project.org/>

**VignetteBuilder** R.rsp

**NeedsCompilation** no

**Author** Kevin R. Coombes [cre, aut],

CombinedWeights-class *Class "CombinedWeights"*

---

## Description

The CombinedWeights object class merges the weight matrices for all data sets in a plasma object.

## Usage

```
combineAllWeights(pl)
## S4 method for signature 'CombinedWeights'
summary(object, ...)
## S4 method for signature 'CombinedWeights'
image(x, ...)
stdize(object, type = c("standard", "robust"))
interpret(object, component, alpha = 0.05)
```

## Arguments

pl	An object of the plasma class.
object	An object of the CombinedWeightss class.
x	An object of the CombinedWeightss class.
type	A single character string indicating how to standardize the object. Legal value are "standard" or "robust".
component	A single character string; which componen should be interpreted.
alpha	A single numerical value between 0 and 1; what significance value should be used to select important features.
...	Ignored; potentially, extra arguments to the summary or image methods.

## Value

The combineAllWeights function returns a newly constructed object of the CombinedWeights class. The summary method returna list containing four matrices. Each matrix has one row for each omics data set and one column for each model component. Each amtric contains different summary statistics, including the Mean, SD, Median, and MAD.

## Objects from the Class

Objects are defined using the combineAllWeights functions. Simply supply an object of class plasma.

**Slots**

**combined:** a matrix of the original variables in dataset N as rows and the PLS components M as columns.

**featureSize:** a numeric (usually integer) vector that stores the number of features in each omics data set.

**dataSource:** a factor indicating which omics data set each feature came from.

**Methods**

**summary:** outputs summary statistics for the contributions of dataset N to components from all datasets in the case of `getAllWeights` or dataset M in the case of `getCompositeWeights`.

**Author(s)**

Kevin R. Coombes <krc@silicovore.com>, Kyoko Yamaguchi <kyoko.yamaguchi@osumc.edu>

**Examples**

```
f1s <- try(loadESCAdata())
if (inherits(f1s, "try-error")) {
  stop("Unable to load data from remote server.")
}
# restrict data set size
M0 <- with(plasmaEnv, prepareMultiOmics(
  assemble[c("ClinicalBin", "ClinicalCont", "RPPA")], Outcome))

splitVec <- with(plasmaEnv, rbinom(nrow(Outcome), 1, 0.6))
trainD <- M0[, splitVec == 1]
testD <- M0[, splitVec == 0]

firstPass <- fitCoxModels(trainD, "Days", "vital_status", "dead")
p1 <- plasma(object = trainD, multi = firstPass)

getCompositeWeights(object = p1, N = "ClinicalBin", M = "RPPA")

cbin <- getAllWeights(object = p1, N = "ClinicalBin")
summary(cbin)
image(cbin)
heat(cbin, cexCol = 0.5)

cbin01 <- pickSignificant(object = cbin, alpha = 0.01)
image(cbin01)
heat(cbin01, cexCol = 0.5)

getTop(object = cbin01, N = 3)
```

---

Contribution-class      *Class "Contribution"*

---

### Description

The Contribution object class contains the weight matrix between variables and the PLS components. The values in the weight matrix are a numeric representation of how much a variable from the omics datasets contributed to defining the final PLS components.

### Usage

```
getCompositeWeights(object, N, M)
getAllWeights(object, N)
getFinalWeights(object)
getTop(object, N = 1)
pickSignificant(object, alpha)
## S4 method for signature 'Contribution'
summary(object, ...)
## S4 method for signature 'Contribution'
image(x, col = viridis(64), mai = c(1.82, 1.52, 0.32, 0.32), ...)
## S4 method for signature 'Contribution'
heat(object, main = "Contributions", col = viridis(64),
      mai = c(1.52, 0.32, 0.82, 1.82), ...)
```

### Arguments

object	In the first four functions, an object of the plasma class. In the methods described here, an object of the Contributions class.
N	in the function <code>getCompositeWeights</code> , the name of the dataset being modeled. in the function <code>getTop</code> , the number of significant components you want to print.
M	name of the dataset being modeled pairwise with dataset N in the <code>getCompositeWeights</code> function.
alpha	level of significance used in the <code>pickSignificant</code> function.
...	other graphical parameters.
x	an object of the Contributions class.
main	A character vector of length one; the main plot title.
col	A vector of color descriptors.
mai	A vector of four nonnegative numbers.

### Value

The `plasma` function returns a newly constructed object of the plasma class.

## Objects from the Class

Objects are defined using the `getAllWeights`, `getCompositeWeights`, `getTop`, or `pickSignificant` functions. In the simplest scenario, one would enter an object of class `plasma` and any specific parameters associated with the function (see arguments section for more info).

## Slots

**contrib:** a matrix of the original variables in dataset N as rows and the PLS components M as columns.

**datasets:** a character vector that stores the names of the datasets that were specified for the function.

## Methods

**summary:** outputs summary statistics for the contributions of dataset N to components from all datasets in the case of `getAllWeights` or dataset M in the case of `getCompositeWeights`.

**image:** outputs a heatmap of the transposed `contrib` matrix.

**heat:** outputs a clustered heatmap of the `contrib` matrix.

## Author(s)

Kevin R. Coombes <krc@silicovore.com>, Kyoko Yamaguchi <kyoko.yamaguchi@osumc.edu>

## Examples

```
f1s <- try(loadESCAdata())
if (inherits(f1s, "try-error")) {
  stop("Unable to load data from remote server.")
}
# restrict data set size
M0 <- with(plasmaEnv, prepareMultiOmics(
  assemble[c("ClinicalBin", "ClinicalCont", "RPPA")], Outcome))

splitVec <- with(plasmaEnv, rbinom(nrow(Outcome), 1, 0.6))
trainD <- M0[, splitVec == 1]
testD <- M0[, splitVec == 0]

firstPass <- fitCoxModels(trainD, "Days", "vital_status", "dead")
p1 <- plasma(object = trainD, multi = firstPass)

getCompositeWeights(object = p1, N = "ClinicalBin", M = "RPPA")

cbin <- getAllWeights(object = p1, N = "ClinicalBin")
summary(cbin)
image(cbin)
heat(cbin, cexCol = 0.5)

cbin01 <- pickSignificant(object = cbin, alpha = 0.01)
image(cbin01)
heat(cbin01, cexCol = 0.5)
```

```
getTop(object = cbin01, N = 3)
```

---

esca-type-data	<i>ESCA type data</i>
----------------	-----------------------

---

## Description

The CombinedWeights object class merges the weight matrices for all data sets in a plasma object.

## Usage

```
data(tfESCA)
data(mirESCA)
```

## Format

Both tfData and mirESCA are data frames containing two columns. The first column is an ID column containing the TCGA sample barcode for an esophageal cancer sample. The second column, called Type identifies the sample as either "squamous" (for likely squamous cell carcinomas that cluster near head and neck cancers) or "adeno" (for likely adenocarcinomas that cluster near stomach cancers).

## Author(s)

Kevin R. Coombes <krc@silicovore.com>, Kyoko Yamaguchi <kyoko.yamaguchi@osumc.edu>

## Source

All data supplied here are based upon esophageal cancer data generated by the TCGA Research Network (<https://www.cancer.gov/tcga>).

The transcription factor classifications of 196 esophageal cancer into squamous cell carcinoma or adenocarcinoma are taken from work published by Abrams and colleagues in BMC Genomics.

The microRNA classifications of 195 esophageal cancer samples into squamous cell carcinoma or adenocarcinoma are taken from work published by Asiaee and colleagues in J Comput Biol.

Imputation

*Imputation*

---

## Description

Functions to impute missing data in omics data sets.

## Usage

```
meanModeImputer(X)
samplingImputer(X)
```

## Arguments

**X** A numeric matrix, where the columns represent independent observations (patients or samples) and the columns represent measured features (genes, proteins, clinical variables, etc).

## Details

We recommend imputing small amounts of missing data in the input data sets when using the `plasma` package. The underlying issue is that the PLS models we use for individual omics data sets will not be able to make predictions on a sample if even one data point is missing. As a result, if a sample is missing at least one data point in every omics data set, then it will be impossible to use that sample at all.

For a range of available imputation methods and R packages, consult the [CRAN Task View on Missing Data](#). We also recommend the [R-miss-tastic web site on missing data](#). Their simulations suggest that, for purposes of producing predictive models from omics data, the imputation method is not particularly important. Because of the latter finding, we have only implemented two simple imputation methods in the `plasma` package:

1. The `meanModeImputer` function will replace any missing data by the mean value of the observed data if there are more than five distinct values; otherwise, it will replace missing data by the mode. This approach works relatively well for both continuous data and for binary or small categorical data.
2. The `samplingImpute` function replaces missing values by sampling randomly from the observed data distribution.

## Value

Both functions return a numeric matrix of the same size and with the same row and column names as the input variable

## Author(s)

Kevin R. Coombes <krc@silicovore.com>, Kyoko Yamaguchi <kyoko.yamaguchi@osumc.edu>

**Examples**

```
loadESCAdata()
imputed <- with(plasmaEnv, lapply(assemble, samplingImputer) )
imputed <- with(plasmaEnv, lapply(assemble, meanModeImputer))
```

---

MultiOmics-class      *Class "MultiOmics"*

---

**Description**

The prepareMultiOmics function returns a new object of MultiOmics class for use in fitCoxModel.

**Usage**

```
prepareMultiOmics(datalist, outcome)
## S4 method for signature 'MultiOmics'
summary(object, ...)
## S4 method for signature 'MultiOmics,missing'
plot(x, y, ...)
```

**Arguments**

datalist	a list of dataframes formatted to have variables as rows (dimension D) and samples as columns (dimension N).
outcome	a dataframe of clinical outcomes formatted to have sample names as row indexes and variable names as column indexes
object	An object of the MultiOmics class.
x	An object of the MultiOmics class.
y	Nothing; ignored.
...	Extra graphical or other parameters.

**Value**

The prepareMultiOmics function returns a new object of the MultiOmics class.

**Objects from the Class**

Objects should be defined using the prepareMultiOmics constructor. In the simplest case, you enter two objects: a list of dataframes and a dataframe of clinical outcomes.

**Slots**

**data:** A list of dataframes with variables as rows or varying length and samples as columns of uniform length N, where N is the maximum value of non-missing samples in any given dataset. Note that NAs have been added to “pad” to make the column length uniform across data types.

**outcome:** A dataframe of clinical outcomes with variables as columns and samples as rows.

**Methods**

**plot:** Produces a visual representation of the dimensionalities of each dataframe in datalist. D corresponds to the number of variables in each omics dataframe, and N corresponds to samples (or members) whose variable is not entirely missing. Gray areas correspond to missing samples.

**summary:** Produces summary tables corresponding to datasets and outcomes.

**Author(s)**

Kevin R. Coombes <krc@silicovore.com>, Kyoko Yamaguchi <kyoko.yamaguchi@osumc.edu>

**Examples**

```
f1s <- try(loadESCAdata())
if (inherits(f1s, "try-error")) {
  stop("Unable to load data from remote server.")
}
MO <- with(plasmaEnv,
  prepareMultiOmics(datalist = assemble, outcome = Outcome))
plot(MO)
summary(MO)
```

---

MultiplePLSCoxModels-class

*Class "MultiplePLSCoxModels"*

---

**Description**

The MultiplePLSCoxModels object class ... The validMultipleCoxModels function checks if each data set contains the same set of samples. The fitCoxModels function fits many plsRcox-models and returns an S4 object of class MultiplePLSCoxModels. The getSizes function returns a matrix with the list of dataframes of the MultiOmics object as rownames and columns with NT, cNT, and p-values.

**Usage**

```
fitCoxModels(multi, timevar, eventvar, eventvalue, verbose)
## S4 method for signature 'MultiplePLSCoxModels'
summary(object, ...)
## S4 method for signature 'MultiplePLSCoxModels,missing'
plot(x, y, col = c("blue", "red"),
     lwd = 2, xlab = "", ylab = "Fraction Surviving",
     mark.time = TRUE, legloc = "topright", ...)
## S4 method for signature 'MultiplePLSCoxModels'
predict(object, newdata, type = c("components", "risk",
  "split", "survfit"), ...)
```

**Arguments**

<code>multi</code>	an object of class <code>MultiOmics</code> for fitting the model.
<code>timevar</code>	a column in the <code>MultiOmics</code> object in the outcome dataframe containing the time-to-event.
<code>eventvar</code>	a column in the <code>MultiOmics</code> object in the outcome dataframe containing the event.
<code>eventvalue</code>	a character string specifying the value of the event in <code>eventvar</code> .
<code>verbose</code>	logical; should the function report progress.
<code>object</code>	an object of class <code>MultiplePLSCoxModels</code> for outputting the summary.
<code>x</code>	an object of class <code>MultiplePLSCoxModels</code> for plotting the Kaplan-Meier curves.
<code>y</code>	An ignored argument for the plot method.
<code>col</code>	A vector of color specifications. Default is <code>c("blue", "red")</code> .
<code>lwd</code>	A vector specifying the line width. Default is <code>"2"</code> .
<code>xlab</code>	A character string to label the x-axis. Default is <code>""</code> .
<code>ylab</code>	A character string to label the y-axis. Default is <code>"Fraction Surviving"</code> .
<code>mark.time</code>	A logical value; should tickmarks indicate censored data? Default is <code>TRUE</code> .
<code>legloc</code>	A character string indicating where to put the legend. Default is <code>"topright"</code> .
<code>...</code>	Other graphical parameters.
<code>newdata</code>	A <code>MultiOmics</code> object with the same structure as the training data.
<code>type</code>	An enumerated character value.

**Value**

The `fitCoxModels` function returns a newly constructed object of the `MultiplePLSCoxModels` class. The `plot` method invisibly returns the object on which it was invoked. The `summary` method returns no value. The `predict` method returns a list of prediction results, each of which comes from the `predict` method for the [SingleModel-class](#).

**Slots**

`models`: A list of `SingleModel` objects, one for each assay.  
`timevar`: A character matching the name of the column containing the time-to-event.  
`eventvar`: A character matching the name of the column containing the event.  
`eventvalue`: A character specifying the event in `eventvar`.

**Methods**

**plot**: Plots Kaplan-Meier curves for each omics dataset split into Low Risk and High Risk groups.  
**summary**: Returns a description of the `MultiplePLSCoxModels` object and the names of the omics datasets used to build the model.  
**predict**: usually returns a list of numeric vectors of predicted risk per data type. When `type = "survfit"`, returns a list of `survfit` objects.

**Author(s)**

Kevin R. Coombes <krc@silicovore.com>, Kyoko Yamaguchi <kyoko.yamaguchi@osumc.edu>

**See Also**

fitSingleModel

**Examples**

```
f1s <- try(loadESCAdata())
if (inherits(f1s, "try-error")) {
  stop("Unable to load data from remote server.")
}
# restrict data set size
MO <- with(plasmaEnv, prepareMultiOmics(
  assemble[c("ClinicalBin", "ClinicalCont", "RPPA")], Outcome))

splitVec <- with(plasmaEnv, rbinom(nrow(Outcome), 1, 0.6))
trainD <- MO[, splitVec == 1]
testD <- MO[, splitVec == 0]

firstPass <- fitCoxModels(trainD, "Days", "vital_status", "dead")

summary(firstPass)
plot(firstPass)
getSizes(firstPass)
pre1 <- predict(firstPass, testD)
```

---

plasma-class

*Class "plasma"*

---

**Description**

The plasma object class is returned after running the plasma function. The plasma function uses the PLSRCox components from one dataset as the predictor variables and the PLSRCox components of another dataset as the response variables to fit a partial least squares regression (pls) model. Then, we take the mean of the predictions to create a final matrix of samples versus components.

The matrix of components described earlier is then used to fit a Cox Proportional Hazards (coxph) model with AIC stepwise variable selection to return a final object of class plasma which includes a coxph model with a reduced number of predictors.

**Usage**

```
plasma(object, multi)
## S4 method for signature 'plasma,missing'
plot(x, y, ...)
## S4 method for signature 'plasma'
barplot(height, source, n, direction = c("both", "up", "down"),
```

```

        lhcol = c("cyan", "red"), wt = c("raw", "std"), ...)
## S4 method for signature 'plasma'
predict(object, newdata = NULL, type = c("components", "risk",
    "split"), ...)

```

### Arguments

<code>multi</code>	an object of the <code>MultiplePLSCoxModels</code> class.
<code>object</code>	an object of the <code>plasma</code> class.
<code>height</code>	an object of the <code>plasma</code> class for the <code>barplot</code> method.
<code>x</code>	an object of class <code>plasma</code> for plotting the Kaplan-Meier curves.
<code>y</code>	An ignored argument for the plot method.
<code>source</code>	A length-one character vector; the name of a data set in a <code>plasma</code> object.
<code>n</code>	A length-one integer vector; the number of high-weight features to display.
<code>direction</code>	A length-one character vector; show features with positive weights (up), negative (down), or both.
<code>lhcol</code>	A character vector of length 2, indicating the preferred colors for low (negative) or high (positive) weights.
<code>wt</code>	A character string indicating whether to plot raw weights or standardized weights.
<code>newdata</code>	A <code>MultiOmics</code> object with the same structure as the training data.
<code>type</code>	An enumerated character value.
<code>...</code>	Additional graphical parameters.

### Value

The `plasma` function returns a newly constructed object of the `plasma` class. The `plot` method invisibly returns the object on which it was invoked. The `predict` method returns an object of the `plasmaPredictions` class.

### Objects from the Class

Objects should be defined using the `plasma` function.

### Slots

`traindata`: An object of class `MultiOmics` used for training the model.  
`compModels`: A list containing objects in the form of `plsr`.  
`fullModel`: A `coxph` object with variables (components) selected via AIC stepwise selection.

### Methods

**plot**: Plots a Kaplan-Meier curve of the final `coxph` model that has been categorized into “low risk” and “high risk” based whether it is higher or lower, respectively, than the median value of risk.

**predict**: creates an object of class `plasmaPredictions`.

**barplot**: Produces a barplot of the `n` largest weights assigned to features from the appropriate data source.

**Author(s)**

Kevin R. Coombes <krc@silicovore.com>, Kyoko Yamaguchi <kyoko.yamaguchi@osumc.edu>

**See Also**

plasmaPredictions, plsr

**Examples**

```
f1s <- try(loadESCAdata())
if (inherits(f1s, "try-error")) {
  stop("Unable to load data from remote server.")
}
# restrict data set size
MO <- with(plasmaEnv, prepareMultiOmics(
  assemble[c("ClinicalBin", "ClinicalCont", "RPPA")], Outcome) )

splitVec <- with(plasmaEnv, rbinom(nrow(Outcome), 1, 0.6))
trainD <- MO[, splitVec == 1]
testD <- MO[, splitVec == 0]

firstPass <- fitCoxModels(trainD, "Days", "vital_status", "dead")
p1 <- plasma(object = trainD, multi = firstPass)

plot(p1, legloc = "topright", main = "Training Data")
barplot(p1, "RPPA", 6)
barplot(p1, "RPPA", 10, "up")
```

---

plasmaPredictions-class

*Class "plasmaPredictions"*

---

**Description**

The plasmaPredictions object class is returned when running the predict method on an object of class plasma.

**Usage**

```
## S4 method for signature 'plasmaPredictions,missing'
plot(x, y, col = c("blue", "red"),
     lwd = 2, xlab = "", ylab = "Fraction Surviving",
     mark.time = TRUE, legloc = "topright", ...)
```

**Arguments**

<code>x</code>	An object of the <code>plasmaPredictions</code> class for plotting the Kaplan-Meier curves.
<code>y</code>	An ignored argument for the plot method.
<code>col</code>	A vector of color specifications. Default is <code>c("blue", "red")</code> .
<code>lwd</code>	A vector specifying the line width. Default is <code>"2"</code> .
<code>xlab</code>	A character string to label the x-axis. Default is <code>""</code> .
<code>ylab</code>	A character string to label the y-axis. Default is <code>"Fraction Surviving"</code> .
<code>mark.time</code>	A logical value; should tickmarks indicate censored data? Default is <code>TRUE</code> .
<code>legloc</code>	A character string indicating where to put the legend. Default is <code>"topright"</code> .
<code>...</code>	Other graphical parameters.

**Value**

The `predict` method on an object of the `plasma` class returns an object of the `plasmaPredictions` class. The `plot` method invisibly returns the value on which it was invoked.

**Objects from the Class**

Users should not create objects of this class directly. They will be automatically created when you apply the `predict` method to a fully worked out `plasma` model.

**Slots**

- meanPredictions:** A matrix with samples as rows and factors as columns that is a result of taking the mean of the PLS component predictions from each dataset.
- riskDF:** Object of type `data.frame` containing the original outcome dataframe and additional columns for "Risk", and "Split", corresponding to the risk of the event calculated by the model, and patient assignment to low versus high-risk groups, respectively.
- riskModel:** Object of type `coxph` that uses predicted Risk (continuous) as the predictor variable and survival as the response variable. See documentation for `link{coxph}`.
- splitModel:** Object of type `coxph` that uses predicted Split (predicted Risk categorized into "high" and "low" risk by the median predicted Risk) as the predictor variable and survival as the response variable. See documentation for `link{coxph}`.
- SF:** Object of type `survfit` which is used by the `plot` method to plot Kaplan-Meier curves grouped by predicted Split. See documentation for `link{survfit}`.

**Methods**

**plot:** Produces Kaplan-Meier curves for the low risk and high risk groups.

**Note**

An object of `plasmaPredictions` class contains many models that are similar to an object of `MultiplePLSCoxModels` class.

  assemble[c("ClinicalBin", "ClinicalCont", "RPPA")], Outcome))

splitVec <- with(plasmaEnv, rbinom(nrow(Outcome), 1, 0.6))
trainD <- MO[, splitVec == 1]
testD <- MO[, splitVec == 0]

firstPass <- fitCoxModels(trainD, "Days", "vital_status", "dead")
pl <- plasma(object = trainD, multi = firstPass)

testpred <- predict(pl, testD)
plot(testpred, main = "Testing", xlab = "Time (Days)")
```

---

SingleModel-class      *Class "SingleModel"*

---

**Description**

The `fitSingleModel` function takes in an object of `MultiOmics` class and returns a new object of `SingleModel` class.

**Usage**

```
fitSingleModel(multi, N, timevar, eventvar, eventvalue)
## S4 method for signature 'SingleModel'
summary(object, ...)
## S4 method for signature 'SingleModel,missing'
plot(x, y, col = c("blue", "red"),
     lwd = 2, xlab = "", ylab = "Fraction Surviving",
     mark.time = TRUE, legloc = "topright", ...)
## S4 method for signature 'SingleModel'
predict(object, newdata, type = c("components", "risk",
  "split", "survfit"), ...)
```

**Arguments**

<code>multi</code>	an object of class <code>MultiOmics</code> for fitting the model.
<code>N</code>	A character string identifying the data set being modeled.
<code>timevar</code>	a column in the <code>MultiOmics</code> object in the outcome dataframe containing the time-to-event.
<code>eventvar</code>	a column in the <code>MultiOmics</code> object in the outcome dataframe containing the event.
<code>eventvalue</code>	a character string specifying the value of the event.
<code>x</code>	an object of class <code>plsRcoxmodel</code> for plotting the Kaplan-Meier curves.
<code>y</code>	An ignored argument for the plot method.
<code>col</code>	A vector of color specifications.
<code>lwd</code>	A vector specifying the line width.
<code>xlab</code>	A character string to label the x-axis.
<code>ylab</code>	A character string to label the y-axis.
<code>mark.time</code>	A logical value; should tickmarks indicate censored data?
<code>legloc</code>	A character string indicating where to put the legend.
<code>object</code>	an object of class <code>SingleModel</code> .
<code>newdata</code>	A <code>MultiOmics</code> object with the same structure as the training data.
<code>type</code>	An enumerated character value.
<code>...</code>	other parameters used in graphing or prediction.

**Value**

The `fitSingleModel` function returns a newly constructed object of the `SingleModel` class. The `plot` method invisibly returns the value on which it was invoked. The `summary` method returns an object summarizing the final model produced by PLS R cox regression. The `predict` method returns either a vector or matrix depending on the type of predictions requested.

**Slots**

- `plsmo`: Object of class `plsRcoxmodel` containing the fitted model.
- `Xout`: Object of type `data.frame` containing the original outcome dataframe and additional columns for "Risk", and "Split", corresponding to the risk of the event calculated by the model, and patient assignment to low versus high-risk groups, respectively.
- `dsname`: A character vector of length one; the name of the data set being modeled from a `MultiOmics` object.
- `SF`: Object of type `survfit` which is used by the `plot` method to plot Kaplan-Meier curves grouped by predicted Split. See documentation for `link{survfit}`.
- `riskModel`: Object of type `coxph` that uses predicted Risk (continuous) as the predictor variable and survival as the response variable. See documentation for `link{coxph}`.
- `splitModel`: Object of type `coxph` that uses predicted Split (predicted Risk categorized into "high" and "low" risk by the median predicted Risk) as the predictor variable and survival as the response variable. See documentation for `link{coxph}`.

**Methods**

**plot:** Plots Kaplan-Meier curves for each omics dataset split into Low Risk and High Risk groups.

**summary:** Returns a description of the `MultiplePLSCoxModels` object and the names of the omics datasets used to build the model.

**predict:** Usually, a numeric vector containing the predicted risk values. However, when using `type = "survfit"`, the return value is a `survfit` object from the `survival` package.

TCGA-ESCA

*Esophageal carcinoma (ESCA) data or lung squamous cell carcinoma (LUSC) data from The Cancer Genome Atlas (TCGA).*

---

**Description**

The TCGA-ESCA dataset contains the objects `assemble`, `Outcome`, and `m450info` for building the `MultiOmics` object. Because its size exceeds the CRAN limits, the data is stored on a remote server and must be loaded using the function `loadESCAdata`.

The TCGA-LUSC1 dataset is a parallel object for lung squamous cell carcinoma (LUSC) data, which must be loaded using the `loadLUSCdata` function.

**Usage**

```
loadESCAdata(env = plasmaEnv)
loadLUSCdata(env = plasmaEnv)
```

**Arguments**

`env` an environment in which to load the data. The default value is a private environment in the package, accessible as `plasmaEnv`. To make access easier, you can use `globalenv()` or `.GlobalEnv`.

**Format**

The “TCGA-ESCA” dataset contains the following:

`assemble` A list of 7 different omics dataframes with varying numbers of features as rows (D) and varying number of patients as columns (N). Note that some of these omics dataframes had been manipulated to contain NAs, where these may be complete on the GDC Data Portal from which these data originally came. This was done to illustrate the capability of the `plasma` package on working with missing data.

`ClinicalBin` a dataframe (53x185) of clinical binary values.

`ClinicalCont` a dataframe (6x185) of clinical continuous values.

`MAF` a dataframe (566x184) of minor allele frequencies (MAF) that have been converted to binary based on whether they had a MAF greater than 0.03 (1) or not (0).

`Meth450` a dataframe (1454x185) of continuous beta values from the Illumina Infinium HumanMethylation450 arrays. The features in this dataframe have been filtered on mean greater than 0.15 and a standard deviation greater than 0.3.

`miRSeq` a dataframe (926x166) of continuous counts values from microRNA (miRNA) sequencing. The features in this dataframe have been filtered on a standard deviation of 0.05.

`mRNASeq` a dataframe (2520x157) of continuous counts values from mRNA sequencing data. The features in this dataframe have been filtered on a mean greater than 4 and a standard deviation greater than 0.7.

`RPPA` a dataframe (192x126) of continuous protein expression values from reverse phase protein array (RPPA) assays.

`Outcome` a dataframe (185x5) containing the survival outcomes for the patients in `assemble`.

`m450info` a dataframe (1454x3) containing gene symbol, chromosome number, and genomic coordinate IDs corresponding to the features (or “probes”) in `Meth450`.
