New Foreword

On October 1, 2001 Axiom was withdrawn from the market and ended life as a commercial product. On September 3, 2002 Axiom was released under the Modified BSD license, including this document. On August 27, 2003 Axiom was released as free and open source software available for download from the Free Software Foundation's website, Savannah.

Work on Axiom has had the generous support of the Center for Algorithms and Interactive Scientific Computation (CAISS) at City College of New York. Special thanks go to Dr. Gilbert Baumslag for his support of the long term goal.

The online version of this documentation is roughly 1000 pages. In order to make printed versions we've broken it up into three volumes. The first volume is tutorial in nature. The second volume is for programmers. The third volume is reference material. We've also added a fourth volume for developers. All of these changes represent an experiment in print-on-demand delivery of documentation. Time will tell whether the experiment succeeded.

Axiom has been in existence for over thirty years. It is estimated to contain about three hundred man-years of research and has, as of September 3, 2003, 143 people listed in the credits. All of these people have contributed directly or indirectly to making Axiom available. Axiom is being passed to the next generation. I'm looking forward to future milestones.

With that in mind I've introduced the theme of the "30 year horizon". We must invent the tools that support the Computational Mathematician working 30 years from now. How will research be done when every bit of mathematical knowledge is online and instantly available? What happens when we scale Axiom by a factor of 100, giving us 1.1 million domains? How can we integrate theory with code? How will we integrate theorems and proofs of the mathematics with space-time complexity proofs and running code? What visualization tools are needed? How do we support the conceptual structures and semantics of mathematics in effective ways? How do we support results from the sciences? How do we teach the next generation to be effective Computational Mathematicians?

The "30 year horizon" is much nearer than it appears.

Tim Daly
CAISS, City College of New York
November 10, 2003 ((iHy))

Chapter 1

Chapter Overview

This book contains the domains in Axiom, in alphabetical order.

Each domain has an associated 'dotpic' chunk which only lists the domains, categories, and packages that are in the layer immediately below in the build order. For the full list see the algebra Makefile where this information is maintained.

Each domain is preceded by a picture. The picture indicates several things. The colors indicate whether the name refers to a category, domain, or package. An ellipse means that the name refers to something in the bootstrap set. Thus,

minPoly operator rootOf ***?

<package AF AlgebraicFunction>≡

)abbrev package AF AlgebraicFunction

++ Author: Manuel Bronstein

++ Date Created: 21 March 1988

++ Date Last Updated: 11 November 1993

++ Description:

++ This package provides algebraic functions over an integral domain.

++ Keywords: algebraic, function.

AlgebraicFunction(R, F): Exports == Implementation where

R: Join(OrderedSet, IntegralDomain)

F: FunctionSpace R

```
SE ==> Symbol
Z  ==> Integer
Q  ==> Fraction Z
OP ==> BasicOperator
K  ==> Kernel F
P  ==> SparseMultivariatePolynomial(R, K)
UP ==> SparseUnivariatePolynomial F
UPR ==> SparseUnivariatePolynomial R
ALGOP ==> "%alg"
SPECIALDISP ==> "%specialDisp"
SPECIALDIFF ==> "%specialDiff"
```

Exports ==> with

```
rootOf : (UP, SE) -> F
++ rootOf(p, y) returns y such that \spad{p(y) = 0}.
++ The object returned displays as \spad{'y}.
operator: OP -> OP
++ operator(op) returns a copy of \spad{op} with the domain-dependent
++ properties appropriate for \spad{F}.
++ Error: if op is not an algebraic operator, that is,
++ an nth root or implicit algebraic operator.
belong? : OP -> Boolean
++ belong?(op) is true if \spad{op} is an algebraic operator, that is,
++ an nth root or implicit algebraic operator.
inrootof: (UP, F) -> F
++ inrootof(p, x) should be a non-exported function.
-- un-export when the compiler accepts conditional local functions!
droot : List F -> OutputForm
++ droot(l) should be a non-exported function.
-- un-export when the compiler accepts conditional local functions!
if R has RetractableTo Integer then
"*)" : (F, Q) -> F
++ x ** q is \spad{x} raised to the rational power \spad{q}.
minPoly: K -> UP
++ minPoly(k) returns the defining polynomial of \spad{k}.
definingPolynomial: F -> F
++ definingPolynomial(f) returns the defining polynomial of \spad{f}
++ as an element of \spad{F}.
++ Error: if f is not a kernel.
iroot : (R, Z) -> F
++ iroot(p, n) should be a non-exported function.
-- un-export when the compiler accepts conditional local functions!
```

Implementation ==> add

```

Exports ==> with
  rootSplit: F -> F
    ++ rootSplit(f) transforms every radical of the form
    ++ \spad{(a/b)**(1/n)} appearing in f into \spad{a**(1/n) / b**(1/n)}.
    ++ This transformation is not in general valid for all
    ++ complex numbers \spad{a} and b.
  ratDenom : F -> F
    ++ ratDenom(f) rationalizes the denominators appearing in f
    ++ by moving all the algebraic quantities into the numerators.
  ratDenom : (F, F) -> F
    ++ ratDenom(f, a) removes \spad{a} from the denominators in f
    ++ if \spad{a} is an algebraic kernel.
  ratDenom : (F, List F) -> F
    ++ ratDenom(f, [a1,...,an]) removes the ai's which are
    ++ algebraic kernels from the denominators in f.
  ratDenom : (F, List K) -> F
    ++ ratDenom(f, [a1,...,an]) removes the ai's which are
    ++ algebraic from the denominators in f.
  ratPoly : F -> SparseUnivariatePolynomial F
    ++ ratPoly(f) returns a polynomial p such that p has no
    ++ algebraic coefficients, and \spad{p(f) = 0}.
  if R has Join(OrderedSet, GcdDomain, RetractableTo Integer)
  and F has FunctionSpace(R) then
    rootPower : F -> F
      ++ rootPower(f) transforms every radical power of the form
      ++ \spad{(a**(1/n))**m} into a simpler form if \spad{m} and
      ++ \spad{n} have a common factor.
    rootProduct: F -> F
      ++ rootProduct(f) combines every product of the form
      ++ \spad{(a**(1/n))**m * (a**(1/s))**t} into a single power
      ++ of a root of \spad{a}, and transforms every radical power
      ++ of the form \spad{(a**(1/n))**m} into a simpler form.
    rootSimp : F -> F
      ++ rootSimp(f) transforms every radical of the form
      ++ \spad{(a * b**(q*n+r))**(1/n)} appearing in f into
      ++ \spad{b**q * (a * b**r)**(1/n)}.
      ++ This transformation is not in general valid for all
      ++ complex numbers b.
    rootKerSimp: (OP, F, N) -> F
      ++ rootKerSimp(op,f,n) should be local but conditional.

AnnaNumericalOptimizationPackage(): with
  measure:NumericalOptimizationProblem -> Measure
    ++ measure(prob) is a top level ANNA function for identifying the most
    ++ appropriate numerical routine from those in the routines table
    ++ provided for solving the numerical optimization problem defined by
    ++ \axiom{prob} by checking various attributes of the functions and
    ++ calculating a measure of compatibility of each routine to these
    ++ attributes.
    ++
    ++ It calls each \axiom{domain} of \axiom{category}
    ++ \axiomType{NumericalOptimizationCategory} in turn to calculate all
    ++ measures and returns the best i.e. the name of the most
    ++ appropriate domain and any other relevant information.

  measure:(NumericalOptimizationProblem,RT) -> Measure
    ++ measure(prob,R) is a top level ANNA function for identifying the most
    ++ appropriate numerical routine from those in the routines table
    ++ provided for solving the numerical optimization problem defined by
    ++ \axiom{prob} by checking various attributes of the functions and
    ++ calculating a measure of compatibility of each routine to these
    ++ attributes.
    ++
    ++ It calls each \axiom{domain} listed in \axiom{R} of \axiom{category}
    ++ \axiomType{NumericalOptimizationCategory} in turn to calculate all
    ++ measures and returns the best i.e. the name of the most
    ++ appropriate domain and any other relevant information.

  optimize:(NumericalOptimizationProblem,RT) -> Result
    ++ optimize(prob,routines) is a top level ANNA function to
    ++ minimize a function or a set of functions with any constraints
    ++ as defined within \axiom{prob}.
    ++
    ++ It iterates over the \axiom{domains} listed in \axiom{routines} of
    ++ \axiomType{NumericalOptimizationCategory}
    ++ to get the name and other relevant information of the best
    ++ \axiom{measure} and then optimize the function on that \axiom{domain}.

```

```

optimize:NumericalOptimizationProblem -> Result
++ optimize(prob) is a top level ANNA function to
++ minimize a function or a set of functions with any constraints
++ as defined within \axiom{prob}.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \axiom{measure} and then optimize the function on that \axiom{domain}.

goodnessOfFit:NumericalOptimizationProblem -> Result
++ goodnessOfFit(prob) is a top level ANNA function to
++ check to goodness of fit of a least squares model
++ as defined within \axiom{prob}.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \axiom{measure} and then optimize the function on that \axiom{domain}.
++ It then calls the numerical routine \axiomType{E04YCF} to get estimates
++ of the variance-covariance matrix of the regression coefficients of
++ the least-squares problem.
++
++ It thus returns both the results of the optimization and the
++ variance-covariance calculation.

optimize:(EF,LF,LOCF,LEF,LOCF) -> Result
++ optimize(f,start,lower,cons,upper) is a top level ANNA function to
++ minimize a function, \axiom{f}, of one or more variables with the
++ given constraints.
++
++ These constraints may be simple constraints on the variables
++ in which case \axiom{cons} would be an empty list and the bounds on
++ those variables defined in \axiom{lower} and \axiom{upper}, or a
++ mixture of simple, linear and non-linear constraints, where
++ \axiom{cons} contains the linear and non-linear constraints and
++ the bounds on these are added to \axiom{upper} and \axiom{lower}.
++
++ The parameter \axiom{start} is a list of the initial guesses of the
++ values of the variables.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \axiom{measure} and then optimize the function on that \axiom{domain}.

```

```

optimize:(EF,LF,LOCF,LOCF) -> Result
++ optimize(f,start,lower,upper) is a top level ANNA function to
++ minimize a function, \axiom{f}, of one or more variables with
++ simple constraints. The bounds on
++ the variables are defined in \axiom{lower} and \axiom{upper}.
++
++ The parameter \axiom{start} is a list of the initial guesses of the
++ values of the variables.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \axiom{measure} and then optimize the function on that \axiom{domain}.

optimize:(EF,LF) -> Result
++ optimize(f,start) is a top level ANNA function to
++ minimize a function, \axiom{f}, of one or more variables without
++ constraints.
++
++ The parameter \axiom{start} is a list of the initial guesses of the
++ values of the variables.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \axiom{measure} and then optimize the function on that \axiom{domain}.

optimize:(LEF,LF) -> Result
++ optimize(lf,start) is a top level ANNA function to
++ minimize a set of functions, \axiom{lf}, of one or more variables
++ without constraints i.e. a least-squares problem.
++
++ The parameter \axiom{start} is a list of the initial guesses of the
++ values of the variables.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \axiom{measure} and then optimize the function on that \axiom{domain}.

goodnessOfFit:(LEF,LF) -> Result
++ goodnessOfFit(lf,start) is a top level ANNA function to
++ check to goodness of fit of a least squares model i.e. the minimization
++ of a set of functions, \axiom{lf}, of one or more variables without
++ constraints.
++

```

```

++ The parameter \axiom{start} is a list of the initial guesses of the
++ values of the variables.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \axiom{measure} and then optimize the function on that \axiom{domain}.
++ It then calls the numerical routine \axiomType{E04YCF} to get estimates
++ of the variance-covariance matrix of the regression coefficients of
++ the least-squares problem.
++
++ It thus returns both the results of the optimization and the
++ variance-covariance calculation.

++ goodnessOfFit(lf,start) is a top level function to iterate over
++ the \axiom{domains} of \axiomType{NumericalOptimizationCategory}
++ to get the name and other relevant information of the best
++ \axiom{measure} and then optimize the function on that \axiom{domain}.
++ It then checks the goodness of fit of the least squares model.

AnnaOrdinaryDifferentialEquationPackage(): with
solve:(NumericalODEProblem) -> Result
++ solve(odeProblem) is a top level ANNA function to solve numerically a
++ system of ordinary differential equations i.e. equations for the
++ derivatives y[1]'.y[n]' defined in terms of x,y[1]..y[n], together
++ with starting values for x and y[1]..y[n] (called the initial
++ conditions), a final value of x, an accuracy requirement and any
++ intermediate points at which the result is required.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{OrdinaryDifferentialEquationsSolverCategory}
++ to get the name and other
++ relevant information of the the (domain of the) numerical
++ routine likely to be the most appropriate,
++ i.e. have the best \axiom{measure}.
++
++ The method used to perform the numerical
++ process will be one of the routines contained in the NAG numerical
++ Library. The function predicts the likely most effective routine
++ by checking various attributes of the system of ODE's and calculating
++ a measure of compatibility of each routine to these attributes.
++
++ It then calls the resulting 'best' routine.
solve:(NumericalODEProblem,RT) -> Result
++ solve(odeProblem,R) is a top level ANNA function to solve numerically a
++ system of ordinary differential equations i.e. equations for the
++ derivatives y[1]'.y[n]' defined in terms of x,y[1]..y[n], together
++ with starting values for x and y[1]..y[n] (called the initial
++ conditions), a final value of x, an accuracy requirement and any
++ intermediate points at which the result is required.
++
++ It iterates over the \axiom{domains} of
++ \axiomType{OrdinaryDifferentialEquationsSolverCategory} contained in
++ the table of routines \axiom{R} to get the name and other
++ relevant information of the the (domain of the) numerical

AnnaPartialDifferentialEquationPackage(): with
solve:(NumericalPDEProblem) -> Result
++ solve(PDEProblem) is a top level ANNA function to solve numerically a syst
++ of partial differential equations.
++
++ The method used to perform the numerical
++ process will be one of the routines contained in the NAG numerical
++ Library. The function predicts the likely most effective routine
++ by checking various attributes of the system of PDE's and calculating
++ a measure of compatibility of each routine to these attributes.
++
++ It then calls the resulting 'best' routine.
++
++ ** At the moment, only Second Order Elliptic Partial Differential
++ Equations are solved **
solve:(NumericalPDEProblem,RT) -> Result
++ solve(PDEProblem,routines) is a top level ANNA function to solve numerical
++ of partial differential equations.
++
++ The method used to perform the numerical
++ process will be one of the routines contained in the NAG numerical
++ Library. The function predicts the likely most effective routine
++ by checking various attributes of the system of PDE's and calculating
++ a measure of compatibility of each routine to these attributes.
++
++ It then calls the resulting 'best' routine.
++
++ ** At the moment, only Second Order Elliptic Partial Differential
++ Equations are solved **
solve:(F,F,F,F,NNI,NNI,LEF,List LEF,ST,DF) -> Result
++ solve(xmin,ymin,xmax,ymax,ngx,ngy,pde,bounds,st,tol) is a top level
++ ANNA function to solve numerically a system of partial differential
++ equations. This is defined as a list of coefficients (\axiom{pde}),
++ a grid (\axiom{xmin}, \axiom{ymin}, \axiom{xmax}, \axiom{ymax},
++ \axiom{ngx}, \axiom{ngy}), the boundary values (\axiom{bounds}) and a
++ tolerance requirement (\axiom{tol}). There is also a parameter
++ (\axiom{st}) which should contain the value "elliptic" if the PDE is
++ known to be elliptic, or "unknown" if it is uncertain. This causes the

```

```

++ routine to check whether the PDE is elliptic.
++
++ The method used to perform the numerical
++ process will be one of the routines contained in the NAG numerical
++ Library. The function predicts the likely most effective routine
++ by checking various attributes of the system of PDE's and calculating
++ a measure of compatibility of each routine to these attributes.
++
++ It then calls the resulting 'best' routine.
++
++ ** At the moment, only Second Order Elliptic Partial Differential
++ Equations are solved **
solve:(F,F,F,F,NNI,NNI,LEF,List LEF,ST) -> Result
++ solve(xmin,ymin,xmax,ymax,ngx,ngy,pde,bounds,st) is a top level
++ ANNA function to solve numerically a system of partial differential
++ equations. This is defined as a list of coefficients (\axiom{pde}),
++ a grid (\axiom{xmin}, \axiom{ymin}, \axiom{xmax}, \axiom{ymax},
++ \axiom{ngx}, \axiom{ngy}) and the boundary values (\axiom{bounds}).
++ A default value for tolerance is used. There is also a parameter
++ (\axiom{st}) which should contain the value "elliptic" if the PDE is
++ known to be elliptic, or "unknown" if it is uncertain. This causes the
++ routine to check whether the PDE is elliptic.
++
++ The method used to perform the numerical

++
++ It then calls the resulting 'best' routine.
++
++ ** At the moment, only Second Order Elliptic Partial Differential
++ Equations are solved **
measure:(NumericalPDEProblem) -> Measure
++ measure(prob) is a top level ANNA function for identifying the most
++ appropriate numerical routine from those in the routines table
++ provided for solving the numerical PDE
++ problem defined by \axiom{prob}.
++
++ It calls each \axiom{domain} of \axiom{category}
++ \axiomType{PartialDifferentialEquationsSolverCategory} in turn to
++ calculate all measures and returns the best i.e. the name of
++ the most appropriate domain and any other relevant information.
++ It predicts the likely most effective NAG numerical
++ Library routine to solve the input set of PDEs
++ by checking various attributes of the system of PDEs and calculating

```

```

    ++ a measure of compatibility of each routine to these attributes.
measure:(NumericalPDEProblem,RT) -> Measure
    ++ measure(prob,R) is a top level ANNA function for identifying the most
    ++ appropriate numerical routine from those in the routines table
    ++ provided for solving the numerical PDE
    ++ problem defined by \axiom{prob}.
    ++
    ++ It calls each \axiom{domain} listed in \axiom{R} of \axiom{category}
    ++ \axiomType{PartialDifferentialEquationsSolverCategory} in turn to
    ++ calculate all measures and returns the best i.e. the name of
    ++ the most appropriate domain and any other relevant information.
    ++ It predicts the likely most effective NAG numerical
    ++ Library routine to solve the input set of PDEs
    ++ by checking various attributes of the system of PDEs and calculating
    ++ a measure of compatibility of each routine to these attributes.

++ AMS Classification:

++ Keywords:

++ Description:

++ \spadtype{AnyFunctions1} implements several utility functions for
 ++ working with \spadtype{Any}. These functions are used to go back
 ++ and forth between objects of \spadtype{Any} and objects of other
 ++ types.

AnyFunctions1(S:Type): with

coerce : S -> Any

++ coerce(s) creates an object of \spadtype{Any} from the
 ++ object \spad{s} of type \spad{S}.

retractIfCan: Any -> Union(S, "failed")

++ retractIfCan(a) tries change \spad{a} into an object
 ++ of type \spad{S}. If it can, then such an object is
 ++ returned. Otherwise, "failed" is returned.

retractable?: Any -> Boolean

++ retractable?(a) tests if \spad{a} can be converted
 ++ into an object of type \spad{S}.

retract : Any -> S

```

++ retract(a) tries to convert \spad{a} into an object of
++ type \spad{S}. If possible, it returns the object.
++ Error: if no such retraction is possible.

```
=====
ApplicationProgramInterface examples
=====
```

The `ApplicationProgramInterface` exposes Axiom internal functions which might be useful for understanding, debugging, or creating tools.

The `getDomains` function takes the name of a category and returns a set of domains which inherit from that category:

```
getDomains 'Collection
```

```
{AssociationList, Bits, CharacterClass, DataList, EqTable, FlexibleArray,
GeneralPolynomialSet, GeneralSparseTable, GeneralTriangularSet, HashTable,
IndexedBits, IndexedFlexibleArray, IndexedList, IndexedOneDimensionalArray,
IndexedString, IndexedVector, InnerTable, KeyedAccessFile, Library, List,
ListMultiDictionary, Multiset, OneDimensionalArray, Point, PrimitiveArray,
RegularChain, RegularTriangularSet, Result, RoutinesTable, Set,
SparseTable, SquareFreeRegularTriangularSet, Stream, String, StringTable,
Table, Vector, WuWenTsunTriangularSet}
```

Type: Set Symbol

This can be used to form the set-difference of two categories:

```
difference(getDomains 'IndexedAggregate, getDomains 'Collection)
```

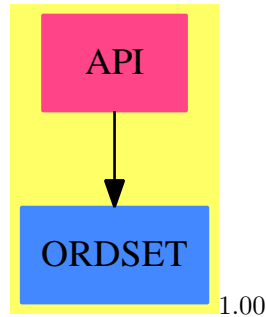

```
{DirectProduct, DirectProductMatrixModule, DirectProductModule,
HomogeneousDirectProduct, OrderedDirectProduct,
SplitHomogeneousDirectProduct}
```

Type: Set Symbol

The `credits` function prints a list of the people who have contributed to the development of Axiom. This is equivalent to the `)credits` command.

The `summary` function prints a short list of useful console commands.

```

The axServer function handles the socket connection on the given port. When it gets a input on the socket it calls the server function on the socket input.

```

⟨package AXSERV AxiomServer⟩+=
  axServer(port:Integer,serverfunc:SExpression->Void):Void ==
    WriteLine$Lisp "listening on port 8085"
    s := SiSock(port,serverfunc)$Lisp
    -- To listen for just one connection and then close the socket
    -- uncomment i := 0.
    i:Integer := 1
    while (i > 0) repeat
      if not null?(SiListen(s)$Lisp)$SExpression then
        w := SiAccept(s)$Lisp
        serverfunc(w)
--      i := 0

```

The multiServ function parses the socket input. It expects either a GET or POST request.

A GET request fetches a new page, calling “getFile”. A POST request starts with

- “command=” which expects axiom interpreter commands. When this is recognized we call the “getCommand” function.
- “lispcall=” which expects lisp interpreter input. When this is recognized we call the “getLisp” function.

```

getDescription

We need to fish around in the data structure to return the piece of documentation for the domain. We have to call the lisp version of GETDATABASE because the version above returns a string object. The string object is missing quotes and cannot be properly read. So we need to get the lisp object and work with it in native form first.

The doc string also contains spad markup which we need to replace with html.

```

```

readTheFile

We have `q` which is a stream which contains the file. We read the file into a string-stream to get it all into one string. We return the string.

```
(package AXSERV AxiomServer)+≡
  readTheFile(q:SExpression):String ==
--    WriteLine("begin reading file")$Lisp
    r := MAKE_-STRING_-OUTPUT_-STREAM()$Lisp
    SiCopyStream(q,r)$Lisp
    filestream:String := GET_-OUTPUT_-STREAM_-STRING(r)$Lisp
    CLOSE(r)$Lisp
    CLOSE(q)$Lisp
--    WriteLine("end reading file")$Lisp
    filestream
```

outputToSocket

We have “`s`” which is the socket, “`filestream`” which is the text of the file to output, and “`contentType`” which is the HTML Content-Type. We construct the HTML header information according to the standard and prepend it to the file. The resulting string is output to the socket.

```
(package AXSERV AxiomServer)+≡
  outputToSocket(s:SExpression,filestream:String,contentType:String):Void ==
    filelength:String := string(#filestream)
    file:String := ""
    nl:String:=STRING(NewLine$Lisp)$Lisp
    file := concat ["Content-Length: ",filelength,nl,nl,file]
    file := concat ["Connection: close",nl,file]
    file := concat ["Content-Type: ",contentType,nl,file]
    file := concat ["HTTP/1.1 200 OK",nl,file]
    file := concat [file,filestream]
--    WriteLine(file)$Lisp
    f:=MAKE_-STRING_-INPUT_-STREAM(file)$Lisp
    SiCopyStream(f,s)$Lisp
    CLOSE(f)$Lisp
    CLOSE(s)$Lisp
```

getCommand

The `getCommand` function is invoked when the HTTP request is a POST and contains the string "command". Essentially the game here is to rebind the various output streams used by Axiom so we can capture the normal output. This function returns a set of HTML 5 div blocks:

1. `stepnum`, the value of `lastStep()`
2. `command`, the value of the command variable
3. `algebra`, the value of the algebra variable
4. `mathml`, the value of the `mathml` variable
5. `type`, the value of `lastType()`

The HTML functions in the hyperdoc browser depend on the order of these variables so do not change this without changing the corresponding functions in the browser HTML.

```
(package AXSERV AxiomServer)+≡
getCommand(s:SExpression,command:String):Void ==
  WriteLine$Lisp concat ["getCommand: ",command]
  SETQ(tmpmathml$Lisp, MAKE_-STRING_-OUTPUT_-STREAM()$Lisp)$Lisp
  SETQ(tmpalgebra$Lisp, MAKE_-STRING_-OUTPUT_-STREAM()$Lisp)$Lisp

```

getInterp

The `getInterp` function is invoked when the HTTP request is a POST and contains the string "command". Essentially the game here is to rebind the various output streams used by Axiom so we can capture the normal output. This function returns a set of HTML 5 div blocks:

1. `stepnum`, the value of `lastStep()`
2. `command`, the value of the command variable
3. `algebra`, the value of the algebra variable
4. `mathml`, the value of the `mathml` variable
5. `type`, the value of `lastType()`

The HTML functions in the hyperdoc browser depend on the order of these variables so do not change this without changing the corresponding functions in the browser HTML.

```
(package AXSERV AxiomServer)+≡
  getInterp(s:SExpression,command:String):Void ==
    WriteLine$Lisp concat ["getInterp: ",command]

      CLOSE(q)$Lisp
      CLOSE(s)$Lisp
```

lastType

To examine the \$internalHistoryTable use the following line

```
)lisp |$internalHistoryTable|
```

We need to pick out first member of internalHistoryTable and then pick out the element with % as first element. Here is an example showing just the first element of the list, which corresponds to the last command.

Note that the last command does not necessarily correspond to the last element of the first element of \$internalHistoryTable as it is in this example.

```
(
  (4 NIL
    (x (value (BasicOperator) WRAPPED . #<vector 09a93bd0>))
    (y (value (BasicOperator) WRAPPED . #<vector 09a93bb4>))
    (% (value (Matrix (Polynomial (Integer))) WRAPPED . #<vector 0982e0e0>))
  )
  ...
)
```

We also need to check for input error in which case the \$internalHistoryTable is not changed and the type retrieved would be that for the last correct input.

```
(package AXSERV AxiomServer)+≡
```

```
lastType():String ==
  SETQ(first$Lisp,FIRST(_$internalHistoryTable$Lisp)$Lisp)$Lisp
  count:Integer := 0
  hisLength:Integer := LIST_-LENGTH(_$internalHistoryTable$Lisp)$Lisp
  length:Integer := LIST_-LENGTH(first$Lisp)$Lisp
  -- This initializes stepSav. The test is a bit of a hack, maybe I'll
  -- figure out the right way to do it later.
  if string stepSav$Lisp = "#<OBJNULL>" then SETQ(stepSav$Lisp, 0$Lisp)$Lisp
  -- If hisLength = 0 then the history table has been reset to NIL
  -- and we're starting numbering over
  if hisLength = 0 then SETQ(stepSav$Lisp, 0$Lisp)$Lisp
  if hisLength > 0 and

)abbrev package BOP1 BasicOperatorFunctions1

++ Tools to set/get common properties of operators

++ Author: Manuel Bronstein

++ Date Created: 28 Mar 1988

++ Date Last Updated: 15 May 1990

++ Description:

++ This package exports functions to set some commonly used properties
++ of operators, including properties which contain functions.

++ Keywords: operator.

BasicOperatorFunctions1(A:SetCategory): Exports == Implementation where

OP ==> BasicOperator

EVAL ==> "%eval"

CONST ==> "%constant"

DIFF ==> "%diff"

OUT ==> OutputForm

IN ==> InputForm

Exports ==> with

evaluate : (OP, List A) -> Union(A, "failed")

++ evaluate(op, [a1,...,an]) checks if op has an "%eval"

++ property f. If it has, then \spad{f(a1,...,an)} is returned, and

++ "failed" otherwise.

evaluate : (OP, List A -> A) -> OP

++ evaluate(op, foo) attaches foo as the "%eval" property

++ of op. If op has an "%eval" property f, then applying op

++ to \spad{f(a1,...,an)} returns the result of \spad{f(a1,...,an)}.

evaluate : (OP, A -> A) -> OP

```

    ++ evaluate(op, foo) attaches foo as the "%eval" property
    ++ of op. If op has an "%eval" property f, then applying op
    ++ to a returns the result of \spad{f(a)}. Argument op must be unary.
evaluate      : OP          -> Union(List A -> A, "failed")
    ++ evaluate(op) returns the value of the "%eval" property of
    ++ op if it has one, and "failed" otherwise.
derivative    : (OP, List (List A -> A)) -> OP
    ++ derivative(op, [foo1,...,foon]) attaches [foo1,...,foon] as
    ++ the "%diff" property of op. If op has an "%diff" property
    ++ \spad{[f1,...,fn]} then applying a derivation D
    ++ to \spad{op(a1,...,an)}
    ++ returns \spad{f1(a1,...,an) * D(a1) + ... + fn(a1,...,an) * D(an)}.
derivative    : (OP, A -> A) -> OP
    ++ derivative(op, foo) attaches foo as the "%diff" property
    ++ of op. If op has an "%diff" property f, then applying a
    ++ derivation D to op(a) returns \spad{f(a) * D(a)}.
    ++ Argument op must be unary.
derivative    : OP -> Union(List(List A -> A), "failed")
    ++ derivative(op) returns the value of the "%diff" property of
    ++ op if it has one, and "failed" otherwise.
if A has OrderedSet then
    constantOperator: A -> OP
        ++ constantOperator(a) returns a nullary operator op
        ++ such that \spad{op()} always evaluate to \spad{a}.
    constantOpIfCan : OP -> Union(A, "failed")
        ++ constantOpIfCan(op) returns \spad{a} if op is the constant
        ++ nullary operator always returning \spad{a}, "failed" otherwise.

=====
Bezier Curve examples
=====
```

A linear Bezier curve is a simple interpolation between the starting point and the ending point based on a parameter t .

Given a start point $a=[x_1,y_1]$ and an endpoint $b=[x_2,y_2]$
 $f(t) == [(1-t)*x_1 + t*x_2, (1-t)*y_1 + t*y_2]$

```
n:=linearBezier([2.0,2.0],[4.0,4.0])
  theMap(BEZIER;linearBezier;2LM;1!0,707)
```

```
[n(t/10.0) for t in 0..10 by 1]
[[2.0,2.0], [2.2,2.2], [2.4,2.4], [2.6,2.6], [2.8,2.8], [3.0,3.0],
 [3.2,3.2], [3.4,3.4], [3.6,3.6], [3.8,3.8], [4.0,4.0]]
```

A quadratic Bezier curve is a simple interpolation between the starting point, a middle point, and the ending point based on a parameter t .

Given a start point $a=[x_1,y_1]$, a middle point $b=[x_2,y_2]$,
 and an endpoint $c=[x_3,y_3]$

$$f(t) == [(1-t)^2 x_1 + 2t(1-t) x_2 + t^2 x_3, \\ (1-t)^2 y_1 + 2t(1-t) y_2 + t^2 y_3]$$

```

n:=quadraticBezier([2.0,2.0],[4.0,4.0],[6.0,2.0])
  theMap(BEZIER;quadraticBezier;3LM;2!0,291)

[n(t/10.0) for t in 0..10 by 1]
  [[2.0,2.0], [2.4,2.36], [2.8,2.64], [3.2,2.84], [3.6,2.96], [4.0,3.0],
   [4.4,2.96], [4.8,2.84], [5.2,2.64], [5.6,2.36], [6.0,2.0]]

```

A cubic Bezier curve is a simple interpolation between the starting point, a left-middle point,, a right-middle point, and the ending point based on a parameter t .

Given a start point $a=[x_1,y_1]$, the left-middle point $b=[x_2,y_2]$, the right-middle point $c=[x_3,y_3]$ and an endpoint $d=[x_4,y_4]$

$$f(t) == [(1-t)^3 x_1 + 3t(1-t)^2 x_2 + 3t^2 (1-t) x_3 + t^3 x_4, \\ (1-t)^3 y_1 + 3t(1-t)^2 y_2 + 3t^2 (1-t) y_3 + t^3 y_4]$$

```

n:=cubicBezier([2.0,2.0],[2.0,4.0],[6.0,4.0],[6.0,2.0])
  theMap(BEZIER;cubicBezier;4LM;3!0,915)

```

```

[n(t/10.0) for t in 0..10 by 1]
  [[2.0,2.0], [2.112,2.54], [2.416,2.96], [2.864,3.26], [3.408,3.44],
   [4.0,3.5], [4.592,3.44], [5.136,3.26], [5.584,2.96], [5.888,2.54],
   [6.0,2.0]]

```

Bezier curves "move" based on moving their control points, which in the case of the three components of a quadratic Bezier curve are the three points given. To see this motion we can show what happens when you "drag" the middle control point along the line from $[-4,4]$ to $[4,4]$ by increments of 1.

First, we form the line as a list of Floats, 9 in all.

```
line:=[[i::Float,4.0] for i in -4..4 by 1]
```

Next, we form a list of functions, each with a different center control point. Notice that the endpoints remain fixed so we expect that the curve will begin and end at the same point but that the midpoint is pulled around.

```
functions:=[quadraticBezier([2.0,2.0],m,[6.0,2.0]) for m in line]
```

Then we form a list of the graphs by calling each function in the above list. Each function call happens 101 times (to include both endpoints). Thus we get a List of Lists of Points of DoubleFloats

```
graphs:= [ [ point( ( functions.i)(j/100.0) )::LIST(DFLOAT) ) _
```

```
for j in 0..100] for i in 1..9]
```

We draw the first graph to see if it looks reasonable:

```
d1:=draw(graphs.1)
```

Since it does we add the other 8 graphs. The 2D graphs can hold up to 9 simultaneous graphs.

```
others:=[graphs.i for i in 2..9]  
for i in 2..9 for graph in others repeat putGraph(d1,[graph],i)
```

and now we display them all on one graph.

```
vp:=makeViewport2D(d1)
```

`f := operator 'f`

(1) `f`

Type: BasicOperator

`D(product(f(i,x),i=1..m),x)`

```

      m      m      f (i,x)
  +-+---+   +-+   ,2
(2)  | |   f(i,x)> -----
      | |       +-+   f(i,x)
      i= 1      i= 1

```

Type: Expression Integer

The `binomial(n, r)` returns the number of subsets of r objects taken among n objects, i.e. $n!/(r! * (n-r)!)$

The binomial coefficients are the coefficients of the series expansion of a power of a binomial, that is

$$\sum_{k=0}^n \binom{n}{k} x^k = (1+x)^n$$

This leads to the famous pascal triangle. First we expose the `OutputForm` domain, which is normally hidden, so we can use it to format the lines.

```
)set expose add constructor OutputForm
```

Next we define a function that will output the list of binomial coefficients right justified with proper spacing:

```
pascalRow(n) == [right(binomial(n,i),4) for i in 0..n]
```

and now we format the whole line so that it looks centered:

```
displayRow(n)==output center blankSeparate pascalRow(n)
```

and we compute the triangle

```
for i in 0..7 repeat displayRow i
```

giving the pretty result:

```
Compiling function pascalRow with type NonNegativeInteger -> List
  OutputForm
Compiling function displayRow with type NonNegativeInteger -> Void
```

```

      1
     1 1
    1 2 1
   1 3 3 1
  1 4 6 4 1
 1 5 10 10 5 1
1 6 15 20 15 6 1
1 7 21 35 35 21 7 1
```

binomial

We currently simplify binomial coefficients only for non-negative integral second argument, using the formula

$$\binom{n}{k} = \frac{1}{k!} \prod_{i=0..k-1} (n-i),$$

except if the second argument is symbolic: in this case $\text{binomial}(n,n)$ is simplified to one.

Note that there are at least two different ways to define binomial coefficients for negative integral second argument. One way, particular suitable for combinatorics, is to set the binomial coefficient equal to zero for negative second argument. This is, partially, also the approach taken in `combinat.spad`, where we find

```
binomial(n, m) ==
  n < 0 or m < 0 or m > n => 0
  m = 0 => 1
```

Of course, here n and m are integers. This definition agrees with the recurrence

$$\binom{n}{k} + \binom{n}{k+1} = \binom{n+1}{k+1}.$$

Alternatively, one can use the formula

$$\binom{n}{k} = \frac{\Gamma(n+1)}{\Gamma(k+1)\Gamma(n-k+1)},$$

and leave the case where $k \in \mathbf{Z}$, $n \in \mathbf{Z}$ and $k \leq n < 0$ undefined, since the limit does not exist in this case:

Since we then have that $n-k+1 \geq 1$, $\Gamma(n-k+1)$ is finite. So it is sufficient to consider $\frac{\Gamma(n+1)}{\Gamma(k+1)}$. On the one hand, we have

$$\lim_{n_0 \rightarrow n} \lim_{k_0 \rightarrow k} \frac{\Gamma(n_0+1)}{\Gamma(k_0+1)} = 0,$$

since for any non-integral n_0 , $\Gamma(n_0+1)$ is finite. On the other hand,

$$\lim_{k_0 \rightarrow k} \lim_{n_0 \rightarrow n} \frac{\Gamma(n_0+1)}{\Gamma(k_0+1)}$$

does not exist, since for non-integral k_0 , $\Gamma(k_0+1)$ is finite while $\Gamma(n_0+1)$ is unbounded.

However, since for $k \in \mathbf{Z}$, $n \in \mathbf{Z}$ and $0 < k < n$ both definitions agree, one could also combine them. This is what, for example, Mathematica does. It seems that MuPAD sets $\text{binomial}(n,n)=1$ for all arguments n , and returns $\text{binomial}(-2, n)$ unevaluated. Provisos may help here.

dvsum and dvdsum

The dvsum and dvdsum operations implement differentiation of sums with and without bounds. Note that the function

$$n \mapsto \sum_{k=1}^n f(k, n)$$

is well defined only for integral values of n greater than or equal to zero. There is not even consensus how to define this function for $n < 0$. Thus, it is not differentiable. Therefore, we need to check whether we erroneously are differentiating with respect to the upper bound or the lower bound, where the same reasoning holds.

Differentiating a sum with respect to its indexing variable correctly gives zero. This is due to the introduction of dummy variables in the internal representation of a sum: the operator `%defsum` takes 5 arguments, namely

1. the summands, where each occurrence of the indexing variable is replaced by
2. the dummy variable,
3. the indexing variable,
4. the lower bound, and
5. the upper bound.

dvprod and dvdprod

The dvprod and dvdprod operations implement differentiation of products with and without bounds. Note again, that we cannot even properly define products with bounds that are not integral.

To differentiate the product, we use Leibniz rule:

$$\frac{d}{dx} \prod_{i=a}^b f(i, x) = \sum_{i=a}^b \frac{\frac{d}{dx} f(i, x)}{f(i, x)} \prod_{i=a}^b f(i, x)$$

There is one situation where this definition might produce wrong results, namely when the product is zero, but axiom failed to recognize it: in this case,

$$\frac{d}{dx} f(i, x) / f(i, x)$$

is undefined for some i . However, I was not able to come up with an example. The alternative definition

$$\frac{d}{dx} \prod_{i=a}^b f(i, x) = \sum_{i=a}^b \left(\frac{d}{dx} f(i, x) \right) \prod_{j=a, j \neq i}^b f(j, x)$$

has the slight (display) problem that we would have to come up with a new index variable, which looks very ugly. Furthermore, it seems to me that more simplifications will occur with the first definition.

```
f := operator 'f
D(product(f(i,x),i=1..m),x)
```

dvpow2

The `dvpow2` operation implements the differentiation of the power operator `%power` with respect to its second argument, i.e., the exponent. It uses the formula

$$\frac{d}{dx}g(y)^x = \frac{d}{dx}e^{x \log g(y)} = \log g(y)g(y)^x.$$

If $g(y)$ equals zero, this formula is not valid, since the logarithm is not defined there. Although strictly speaking 0^x is not differentiable at zero, we return zero for convenience.

4.15 package CDEN CommonDenominator

4.16 CommonDenominator

Exports:

clearDenominator commonDenominator splitDenominator

(package CDEN CommonDenominator)≡

)abbrev package CDEN CommonDenominator

--% CommonDenominator

++ Author: Manuel Bronstein

++ Date Created: 2 May 1988

++ Date Last Updated: 22 Nov 1989

++ Description: CommonDenominator provides functions to compute the
++ common denominator of a finite linear aggregate of elements of
++ the quotient field of an integral domain.

++ Keywords: gcd, quotient, common, denominator.

CommonDenominator(R, Q, A): Exports == Implementation where

R: IntegralDomain

Q: QuotientFieldCategory R

A: FiniteLinearAggregate Q

Exports ==> with

commonDenominator: A -> R

++ commonDenominator([q1,...,qn]) returns a common denominator

++ d for q1,...,qn.

clearDenominator : A -> A

++ clearDenominator([q1,...,qn]) returns \spad{[p1,...,pn]} such that

++ \spad{qi = pi/d} where d is a common denominator for the qi's.

splitDenominator : A -> Record(num: A, den: R)

++ splitDenominator([q1,...,qn]) returns

++ \spad{[[p1,...,pn], d]} such that

++ \spad{qi = pi/d} and d is a common denominator for the qi's.

Implementation ==> add

```

clearDenominator l ==
  d := commonDenominator l
  map(x+->numer(d*x)::Q, l)

splitDenominator l ==
  d := commonDenominator l
  [map(x+->numer(d*x)::Q, l), d]

if R has GcdDomain then
  qlcm: (Q, Q) -> Q

  qlcm(a, b) == lcm(numer a, numer b)::Q
  commonDenominator l == numer reduce(qlcm, map(x+->denom(x)::Q, l), 1)
else
  commonDenominator l == numer reduce("?", map(x+->denom(x)::Q, l), 1)

```

++ Author: J. Grabmeier
++ Date Created: 31 January 1991
++ Date Last Updated: 12 April 1991
++ Basic Operations: factor, pleskenSplit
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords: complex zeros, roots
++ References: J. Grabmeier: On Plesken's root finding algorithm,
++ in preparation
++ A. Schoenhage: The fundamental theorem of algebra in terms of computational
++ complexity, preliminary report, Univ. Tuebingen, 1982
++ Description:
++ \spadtype{ComplexRootFindingPackage} provides functions to
++ find all roots of a polynomial p over the complex number by
++ using Plesken's idea to calculate in the polynomial ring
++ modulo f and employing the Chinese Remainder Theorem.
++ In this first version, the precision (see \spadfunFrom{digits}{Float})
++ is not increased when this is necessary to
++ avoid rounding errors. Hence it is the user's responsibility to
++ increase the precision if necessary.
++ Note also, if this package is called with e.g. \spadtype{Fraction Integer},
++ the precise calculations could require a lot of time.
  
```

```

++ Also note that evaluating the zeros is not necessarily a good check
++ whether the result is correct: already evaluation can cause
++ rounding errors.

public ==> with
complexZeros : UP -> L C
++ complexZeros(p) tries to determine all complex zeros
++ of the polynomial p with accuracy given by the package
++ constant {\em globalEps} which you may change by
++ {\em setErrorBound}.
complexZeros : (UP, R) -> L C
++ complexZeros(p, eps) tries to determine all complex zeros
++ of the polynomial p with accuracy given by {\em eps}.
divisorCascade : (UP,UP, Boolean) -> L FAE
++ divisorCascade(p,tp) assumes that degree of polynomial {\em tp}
++ is smaller than degree of polynomial p, both monic.
++ A sequence of divisions are calculated
++ using the remainder, made monic, as divisor
++ for the the next division. The result contains also the error of the
++ factorizations, i.e. the norm of the remainder polynomial.
++ If {\em info} is {\em true}, then information messages are issued.
divisorCascade : (UP,UP) -> L FAE
++ divisorCascade(p,tp) assumes that degree of polynomial {\em tp}
++ is smaller than degree of polynomial p, both monic.
++ A sequence of divisions is calculated
++ using the remainder, made monic, as divisor
++ for the the next division. The result contains also the error of the
++ factorizations, i.e. the norm of the remainder polynomial.
factor: (UP,R,Boolean) -> FR UP
++ factor(p, eps, info) tries to factor p into linear factors
++ with error atmost {\em eps}. An overall error bound
++ {\em eps0} is determined and iterated tree-like calls

```

```

++ to {\em pleskenSplit} are used to get the factorization.
++ If {\em info} is {\em true}, then information messages are given.
factor: (UP,R) -> FR UP
++ factor(p, eps) tries to factor p into linear factors
++ with error atmost {\em eps}. An overall error bound
++ {\em eps0} is determined and iterated tree-like calls
++ to {\em pleskenSplit} are used to get the factorization.
factor: UP -> FR UP
++ factor(p) tries to factor p into linear factors
++ with error atmost {\em globalEps}, the internal error bound,
++ which can be set by {\em setErrorBound}. An overall error bound
++ {\em eps0} is determined and iterated tree-like calls
++ to {\em pleskenSplit} are used to get the factorization.
graeffe : UP -> UP
++ graeffe p determines q such that \spad{q(-z**2) = p(z)*p(-z)}.
++ Note that the roots of q are the squares of the roots of p.
norm : UP -> R
++ norm(p) determines sum of absolute values of coefficients
++ Note: this function depends on \spadfunFrom{abs}{Complex}.
pleskenSplit: (UP, R, Boolean) -> FR UP
++ pleskenSplit(poly,eps,info) determines a start polynomial {\em start}
++ by using "startPolynomial then it increases the exponent
++ n of {\em start ** n mod poly} to get an approximate factor of
++ {\em poly}, in general of degree "degree poly -1". Then a divisor
++ cascade is calculated and the best splitting is chosen, as soon
++ as the error is small enough.
---+ In a later version we plan
---+ to use the whole information to get a split into more than 2
---+ factors.
++ If {\em info} is {\em true}, then information messages are issued.
pleskenSplit: (UP, R) -> FR UP
++ pleskenSplit(poly, eps) determines a start polynomial {\em start}\
++ by using "startPolynomial then it increases the exponent
++ n of {\em start ** n mod poly} to get an approximate factor of
++ {\em poly}, in general of degree "degree poly -1". Then a divisor
++ cascade is calculated and the best splitting is chosen, as soon
++ as the error is small enough.
---+ In a later version we plan
---+ to use the whole information to get a split into more than 2
---+ factors.
reciprocalPolynomial: UP -> UP
++ reciprocalPolynomial(p) calculates a polynomial which has exactly
++ the inverses of the non-zero roots of p as roots, and the same
++ number of 0-roots.
rootRadius: (UP,R) -> R
++ rootRadius(p,errQuot) calculates the root radius of p with a

```

```

++ maximal error quotient of {\em errQuot}.
rootRadius: UP -> R
++ rootRadius(p) calculates the root radius of p with a
++ maximal error quotient of {\em 1+globalEps}, where
++ {\em globalEps} is the internal error bound, which can be
++ set by {\em setErrorBound}.
schwerpunkt: UP -> C
++ schwerpunkt(p) determines the 'Schwerpunkt' of the roots of the
++ polynomial p of degree n, i.e. the center of gravity, which is
++ {\em coefficient of \spad{x**(n-1)}} divided by
++ {\em n times coefficient of \spad{x**n}}.
setErrorBound : R -> R
++ setErrorBound(eps) changes the internal error bound,
-- by default being {\em 10 ** (-20)} to eps, if R is
++ by default being {\em 10 ** (-3)} to eps, if R is
++ a member in the category \spadtype{QuotientFieldCategory Integer}.
++ The internal {\em globalDigits} is set to
-- {\em ceiling(1/r)**2*10} being {\em 10**41} by default.
++ {\em ceiling(1/r)**2*10} being {\em 10**7} by default.
startPolynomial: UP -> Record(start: UP, factors: FR UP)
++ startPolynomial(p) uses the ideas of Schoenhage's
++ variant of Graeffe's method to construct circles which separate
++ roots to get a good start polynomial, i.e. one whose
++ image under the Chinese Remainder Isomorphism has both entries
++ of norm smaller and greater or equal to 1. In case the
++ roots are found during internal calculations.
++ The corresponding factors
++ are in {\em factors} which are otherwise 1.

CycleIndicators examples
=====
```

This section is based upon the paper J. H. Redfield, ‘‘The Theory of Group-Reduced Distributions’’, American J. Math., 49 (1927) 433-455, and is an application of group theory to enumeration problems. It is a development of the work by P. A. MacMahon on the application of symmetric functions and Hammond operators to combinatorial theory.

The theory is based upon the power sum symmetric functions $s(i)$ which are the sum of the i -th powers of the variables. The cycle index of a permutation is an expression that specifies the sizes of the cycles of a permutation, and may be represented as a partition. A partition of a non-negative integer n is a collection of positive integers called its parts whose sum is n . For example, the partition $(3^2 2 1^2)$ will be used to represent $s^2_3 s_2 s^2_1$ and will indicate that the permutation has two cycles of length 3, one of length 2 and two of length 1. The cycle index of a permutation group is the sum of the cycle indices of its permutations divided by the number of permutations. The cycle indices of certain groups are provided.

The operation `complete` returns the cycle index of the symmetric group of order n for argument n . Alternatively, it is the n -th complete homogeneous symmetric function expressed in terms of power sum symmetric functions.

```
complete 1
(1)
```

Type: SymmetricPolynomial Fraction Integer

```
complete 2
1      1  2
- (2) + - (1 )
2      2
```

Type: SymmetricPolynomial Fraction Integer

```
complete 3
1      1      1  3
- (3) + - (2 1) + - (1 )
3      2      6
```

Type: SymmetricPolynomial Fraction Integer

```
complete 7
1      1      1      1      2      1      1      1      3
```

$$\begin{aligned}
& -\frac{(7)}{7} + -\frac{(6\ 1)}{6} + --\frac{(5\ 2)}{10} + --\frac{(5\ 1\)}{10} + --\frac{(4\ 3)}{12} + -\frac{(4\ 2\ 1)}{8} + --\frac{(4\ 1\)}{24} \\
& + \\
& --\frac{(3\ 1)}{18} + --\frac{(3\ 2\)}{24} + --\frac{(3\ 2\ 1\)}{12} + --\frac{(3\ 1\)}{72} + --\frac{(2\ 1)}{48} + --\frac{(2\ 1\)}{48} \\
& + \\
& ---\frac{(2\ 1\)}{240} + ----\frac{(1\)}{5040}
\end{aligned}$$

Type: SymmetricPolynomial Fraction Integer

The operation `elementary` computes the n -th elementary symmetric function for argument n .

$$\begin{aligned}
& \text{elementary } 7 \\
& -\frac{(7)}{7} - -\frac{(6\ 1)}{6} - --\frac{(5\ 2)}{10} + --\frac{(5\ 1\)}{10} - --\frac{(4\ 3)}{12} + -\frac{(4\ 2\ 1)}{8} - --\frac{(4\ 1\)}{24} \\
& + \\
& --\frac{(3\ 1)}{18} + --\frac{(3\ 2\)}{24} - --\frac{(3\ 2\ 1\)}{12} + --\frac{(3\ 1\)}{72} - --\frac{(2\ 1)}{48} + --\frac{(2\ 1\)}{48} \\
& + \\
& - ----\frac{(2\ 1\)}{240} + ----\frac{(1\)}{5040}
\end{aligned}$$

Type: SymmetricPolynomial Fraction Integer

The operation `alternating` returns the cycle index of the alternating group having an even number of even parts in each cycle partition.

$$\begin{aligned}
& \text{alternating } 7 \\
& -\frac{(7)}{7} + -\frac{(5\ 1\)}{5} + -\frac{(4\ 2\ 1)}{4} + -\frac{(3\ 1)}{9} + --\frac{(3\ 2\)}{12} + --\frac{(3\ 1\)}{36} + --\frac{(2\ 1\)}{24} \\
& + \\
& ----\frac{(1\)}{2520}
\end{aligned}$$

Type: SymmetricPolynomial Fraction Integer

The operation `cyclic` returns the cycle index of the cyclic group.

$$\begin{aligned}
& \text{cyclic } 7 \\
& \frac{1}{6} \frac{7}{1} \frac{7}{7}
\end{aligned}$$

$$-\frac{(7)}{7} + -\frac{(1)}{7}$$

Type: SymmetricPolynomial Fraction Integer

The operation `dihedral` is the cycle index of the dihedral group.

$$\text{dihedral } 7 \\ -\frac{(7)}{7} + -\frac{(2 \ 1)}{2} + --\frac{(1)}{14}$$

Type: SymmetricPolynomial Fraction Integer

The operation `graphs` for argument `n` returns the cycle index of the group of permutations on the edges of the complete graph with `n` nodes induced by applying the symmetric group to the nodes.

$$\text{graphs } 5 \\ -\frac{(6 \ 3 \ 1)}{6} + -\frac{(5)}{5} + -\frac{(4 \ 2)}{4} + -\frac{(3 \ 1)}{6} + -\frac{(2 \ 1)}{8} + --\frac{(2 \ 1)}{12} + ---\frac{(1)}{120}$$

Type: SymmetricPolynomial Fraction Integer

The cycle index of a direct product of two groups is the product of the cycle indices of the groups. Redfield provided two operations on two cycle indices which will be called "cup" and "cap" here. The cup of two cycle indices is a kind of scalar product that combines monomials for permutations with the same cycles. The cap operation provides the sum of the coefficients of the result of the cup operation which will be an integer that enumerates what Redfield called group-reduced distributions.

We can, for example, represent `complete 2 * complete 2` as the set of objects `a a b b` and `complete 2 * complete 1 * complete 1` as `c c d e`.

This integer is the number of different sets of four pairs.

$$\text{cap}(\text{complete } 2**2, \text{complete } 2*\text{complete } 1**2) \\ 4$$

Type: Fraction Integer

For example,

$$\begin{array}{cccc} a \ a \ b \ b & a \ a \ b \ b & a \ a \ b \ b & a \ a \ b \ b \\ c \ c \ d \ e & c \ d \ c \ e & c \ e \ c \ d & d \ e \ c \ c \end{array}$$

This integer is the number of different sets of four pairs no two pairs being equal.

```
cap(elementary 2**2, complete 2*complete 1**2)
2
```

Type: Fraction Integer

For example,

```
a a b b    a a b b
c d c e    c e c d
```

In this case the configurations enumerated are easily constructed, however the theory merely enumerates them providing little help in actually constructing them.

Here are the number of 6-pairs, first from a a a b b c, second from d d e e f g.

```
cap(complete 3*complete 2*complete 1, complete 2**2*complete 1**2)
24
```

Type: Fraction Integer

Here it is again, but with no equal pairs.

```
cap(elementary 3*elementary 2*elementary 1, complete 2**2*complete 1**2)
8
```

Type: Fraction Integer

```
cap(complete 3*complete 2*complete 1, elementary 2**2*elementary 1**2)
8
```

Type: Fraction Integer

The number of 6-triples, first from a a a b b c, second from d d e e f g, third from h h i i j j.

```
eval(cup(complete 3*complete 2*complete 1, cup(complete 2**2*complete 1**2, comp
1500
```

Type: Fraction Integer

The cycle index of vertices of a square is dihedral 4.

```
square:=dihedral 4
1      3  2  1      2  1  4
- (4) + - (2 ) + - (2 1 ) + - (1 )
4      8      4      8
```

Type: SymmetricPolynomial Fraction Integer

The number of different squares with 2 red vertices and 2 blue vertices.

```
cap(complete 2**2,square)
2
```

Type: Fraction Integer

The number of necklaces with 3 red beads, 2 blue beads and 2 green beads.

```
cap(complete 3*complete 2**2,dihedral 7)
18
```

Type: Fraction Integer

The number of graphs with 5 nodes and 7 edges.

```
cap(graphs 5,complete 7*complete 3)
4
```

Type: Fraction Integer

The cycle index of rotations of vertices of a cube.

```
s(x) == powerSum(x)
```

Type: Void

```
cube:=(1/24)*(s 1**8+9*s 2**4 + 8*s 3**2*s 1**2+6*s 4**2)
1 2 1 2 2 3 4 1 8
- (4 ) + - (3 1 ) + - (2 ) + -- (1 )
4 3 8 24
```

Type: SymmetricPolynomial Fraction Integer

The number of cubes with 4 red vertices and 4 blue vertices.

```
cap(complete 4**2,cube)
7
```

Type: Fraction Integer

The number of labeled graphs with degree sequence 2 2 2 1 1 with no loops or multiple edges.

```
cap(complete 2**3*complete 1**2,wreath(elementary 4,elementary 2))
7
```

Type: Fraction Integer

Again, but with loops allowed but not multiple edges.

```
cap(complete 2**3*complete 1**2,wreath(elementary 4,complete 2))
17
```

Type: Fraction Integer

Again, but with multiple edges allowed, but not loops

```
cap(complete 2**3*complete 1**2,wreath(complete 4,elementary 2))
10
```

Type: Fraction Integer

Again, but with both multiple edges and loops allowed

```
cap(complete 2**3*complete 1**2,wreath(complete 4,complete 2))
23
```

Type: Fraction Integer

Having constructed a cycle index for a configuration we are at liberty to evaluate the s_i components any way we please. For example we can produce enumerating generating functions. This is done by providing a function f on an integer i to the value required of s_i , and then evaluating $\text{eval}(f, \text{cycleindex})$.

```
x: ULS(FRAC INT, 'x, 0) := 'x
x
```

Type: UnivariateLaurentSeries(Fraction Integer,x,0)

```
ZeroOrOne: INT -> ULS(FRAC INT, 'x, 0)
Type: Void
```

```
Integers: INT -> ULS(FRAC INT, 'x, 0)
Type: Void
```

For the integers 0 and 1, or two colors.

```
ZeroOrOne n == 1+x**n
Type: Void
```

```
ZeroOrOne 5
5
1 + x
```

Type: UnivariateLaurentSeries(Fraction Integer,x,0)

For the integers 0, 1, 2, ... we have this.

```
Integers n == 1/(1-x**n)
Type: Void
```

```
Integers 5
```

```

      5      10      11
1 + x  + x  + 0(x )
Type: UnivariateLaurentSeries(Fraction Integer,x,0)

```

The coefficient of x^n is the number of graphs with 5 nodes and n edges.

Note that there is an eval function that takes two arguments. It has the signature:

```

((Integer -> D1),SymmetricPolynomial Fraction Integer) -> D1
from EvaluateCycleIndicators D1 if D1 has ALGEBRA FRAC INT

```

This function is not normally exposed (it will not normally be considered in the list of eval functions) as it is only useful for this particular domain. To use it we ask that it be considered thus:

```
)expose EVALCYC
```

and now we can use it:

```

eval(ZeroOrOne, graphs 5)
      2      3      4      5      6      7      8      9      10      11
1 + x + 2x + 4x + 6x + 6x + 4x + 2x + x + x + 0(x )
Type: UnivariateLaurentSeries(Fraction Integer,x,0)

```

The coefficient of x^n is the number of necklaces with n red beads and $n-8$ green beads.

```

eval(ZeroOrOne,dihedral 8)
      2      3      4      5      6      7      8
1 + x + 4x + 5x + 8x + 5x + 4x + x + x
Type: UnivariateLaurentSeries(Fraction Integer,x,0)

```

The coefficient of x^n is the number of partitions of n into 4 or fewer parts.

```

eval(Integers,complete 4)
      2      3      4      5      6      7      8      9      10      11
1 + x + 2x + 3x + 5x + 6x + 9x + 11x + 15x + 18x + 23x + 0(x )
Type: UnivariateLaurentSeries(Fraction Integer,x,0)

```

The coefficient of x^n is the number of partitions of n into 4 boxes containing ordered distinct parts.

```

eval(Integers,elementary 4)
      6      7      8      9      10      11      12      13      14      15      16

```
cap(dihedral 30,complete 7*complete 8*complete 5*complete 10)
49958972383320
```

Type: Fraction Integer

The operation SFunction is the S-function or Schur function of a partition written as a descending list of integers expressed in terms of power sum symmetric functions.

In this case the argument partition represents a tableau shape. For example 3,2,2,1 represents a tableau with three boxes in the first row, two boxes in the second and third rows, and one box in the fourth row. SFunction [3,2,2,1] counts the number of different tableaux of shape 3, 2, 2, 1 filled with objects with an ascending order in the columns and a non-descending order in the rows.

```
sf3221:= SFunction [3,2,2,1]
      1      1      2      1      2      1      1      4      1      2
      -- (6 2) - -- (6 1 ) - -- (4 ) + -- (4 3 1) + -- (4 1 ) - -- (3 2)
      12      12      16      12      24      36
+
      1      2 2      1      2      1      3      1      5      1      4      1      3 2
      -- (3 1 ) - -- (3 2 1) - -- (3 2 1 ) - -- (3 1 ) - --- (2 ) + -- (2 1 )
      36      24      36      72      192      48
+
      1      2 4      1      6      1      8
      -- (2 1 ) - --- (2 1 ) + --- (1 )
      96      144      576
```

Type: SymmetricPolynomial Fraction Integer

This is the number filled with a a b b c c d d.

```
cap(sf3221,complete 2**4)
3
```

Type: Fraction Integer

The configurations enumerated above are:

a a b	a a c	a a d
b c	b b	b b
c d	c d	c c
d	d	d

This is the number of tableaux filled with 1..8.

```
cap(sf3221, powerSum 1**8)
70
```

Type: Fraction Integer

The coefficient of x^n is the number of column strict reverse plane partitions of n of shape $3\ 2\ 2\ 1$.

```
eval(Integers, sf3221)
      9      10      11      12      13      14      15      16      17

++ Author: A. Fortenbacher
++ Date Created: 29 March 1991
++ Date Last Updated: 29 March 1991
++ Basic Operations: dioSolve
++ Related Constructors: Equation, Vector
++ Also See:
++ AMS Classifications:
++ Keywords: Diophantine equation, nonnegative solutions,
++   basis, depth-first-search
++ Reference:
++   M. Clausen, A. Fortenbacher: Efficient Solution of
++   Linear Diophantine Equations. in JSC (1989) 8, 201-216
++ Description:
++   any solution of a homogeneous linear Diophantine equation
++   can be represented as a sum of minimal solutions, which
++   form a "basis" (a minimal solution cannot be represented
++   as a nontrivial sum of solutions)
++   in the case of an inhomogeneous linear Diophantine equation,
++   each solution is the sum of a inhomogeneous solution and
++   any number of homogeneous solutions
++   therefore, it suffices to compute two sets:
++     1. all minimal inhomogeneous solutions
++     2. all minimal homogeneous solutions
++   the algorithm implemented is a completion procedure, which
++   enumerates all solutions in a recursive depth-first-search
++   it can be seen as finding monotone paths in a graph
  
```

VA ==> Vector A

VB ==> Vector B

O2 ==> FiniteLinearAggregateFunctions2(A, VA, B, VB)

Exports ==> with

```

scan    : ((A, B) -> B, DA, B) -> DB
  ++ scan(func,vec,ident) creates a new vector whose elements are
  ++ the result of applying reduce to the binary function func,
  ++ increasing initial subsequences of the vector vec,
  ++ and the element ident.
reduce  : ((A, B) -> B, DA, B) -> B
  ++ reduce(func,vec,ident) combines the elements in vec using the
  ++ binary function func. Argument ident is returned if the vector is empty.
map     : (A -> B, DA) -> DB
  ++ map(f, v) applies the function f to every element of the vector v
  ++ producing a new vector containing the values.

```

```

5.16.1 The Exponential Integral

5.16.2 The E1 function

(Quoted from Segletes[?]):

A number of useful integrals exist for which no exact solutions have been found. In other cases, an exact solution, if found, may be impractical to utilize over the complete domain of the function because of precision limitations associated with what usually ends up as a series solution to the challenging integral. For many of these integrals, tabulated values may be published in various mathematical handbooks and articles. In some handbooks, fits (usually piecewise) also are offered. In some cases, an application may be forced to resort to numerical integration in order to acquire the integrated function. In this context, compact (*i.e.* not piecewise) analytical fits to some of these problematic integrals, accurate to within a small fraction of the numerically integrated value, serve as a useful tool to applications requiring the results of the integration, especially when the integration is required numerous times throughout the course of the application. Furthermore, the ability and methodology to develop intelligent fits, in contrast to the more traditional “brute force” fits, provide the means to minimize parameters and maximize accuracy when tackling some of these difficult functions. The exponential integral will be used as an opportunity to both demonstrate a methodology for intelligent fitting as well as for providing an accurate, compact, analytical fit to the exponential integral.

The exponential integral is a useful class of functions that arise in a variety of applications [...]. The real branch of the family of exponential integrals may be defined as

$$E_n(x) = x^{n-1} \int_x^\infty \frac{e^{-t}}{t^n} dt \quad (5.1)$$

where n , a positive integer, denotes the specific member of the exponential integral family. The argument of the exponential integral, rather than expressing a lower limit of integration as in (1), may be thought of as describing the exponential decay constant, as given in this equivalent (and perhaps more popular) definition of the integral:

$$E_n(x) = \int_1^\infty \frac{e^{-xt}}{t^n} dt \quad (5.2)$$

Integration by parts permits any member of the exponential integral family to be converted to an adjacent member of the family, by way of

$$\int_x^\infty \frac{e^{-t}}{t^{n+1}} dt = \frac{1}{n} \left(\frac{e^{-x}}{x^n} - \int_x^\infty \frac{e^{-t}}{t^n} dt \right) \quad (5.3)$$

expressable in terms of E_n as

$$E_{n+1}(x) = \frac{1}{n} [e^{-x} - xE_n(x)] \quad (n = 1, 2, 3) \quad (5.4)$$

Through recursive employment of this equation, all members of the exponential integral family may be analytically related. However, this technique only allows for the transformation of one integral into another. There remains the problem of evaluating $E_1(x)$. There is an exact solution to the integral of (e^{-t}/t) , appearing in a number of mathematical references [?, ?] which is obtainable by expanding the exponential into a power series and integrating term by term. That exact solution, which is convergent, may be used to specify $E_1(x)$ as

$$E_1(x) = -\gamma - \ln(x) + \frac{x}{1!} - \frac{x^2}{2 \cdot 2!} + \frac{x^3}{3 \cdot 3!} - \dots \quad (5.5)$$

Euler's constant, γ , equal to $0.57721\dots$, arises when the power series expansion for (e^{-t}/t) is integrated and evaluated at its upper limit, as $x \rightarrow \infty$ [?].

Employing eqn (5), however, to evaluate $E_1(x)$ is problematic for finite x significantly larger than unity. One may well ask of the need to evaluate the exponential integral for large x , since the function to be integrated drops off so rapidly that the integral is surely a very flat function. Such reasoning is true when comparing the integrand at large x to that at small x . However, the definition of eqn (1) has as its upper limit not a small value of x , but rather that of ∞ . Therefore, the actual values for $E_n(x)$ are extremely small numbers for large values of x . Thus, it is not sufficient merely to select enough terms of eqn (5) to evaluate the integral to within a value of, for example ± 0.0001 because the actual integral value for large x would be smaller than this arbitrary tolerance. To draw an analogy, it would be like saying that it is good enough to approximate e^{-x} as 0.0 for $x > 10$, since its actual value is within 0.0001 of zero. For some applications, such an approximation may be warranted. In general, though, such an approximation is mathematically unacceptable. Worse yet, as seen from eqns (1) and (2), the need to evaluate the exponential integral for large arguments can arise in real-world problems from either a large integration limit or a large value of an exponential decay constant. Thus, the need to evaluate exponential integrals for large values of the argument is established. It is here that the practical problems with the evaluation of eqn (5) become manifest.

First, the number of terms, N , required to achieve convergence rises rapidly with increasing x , making the summation an inefficient tool, even when expressed as a recursion relation (for three digits of accuracy, N is observed to vary roughly as $9 + 1.6x$, for $1 < x < 7$). More important, however, is the fact that, for calculations of finite precision, the accuracy of the complete summation will be governed by the individual term of greatest magnitude. The source of the problem is that as x is increased, the total summation decreases in magnitude more rapidly than a decaying exponential, while at the same time, the largest individual term in the series is observed to grow rapidly with increasing x (10^1 for $x = 7$, 10^2 for $x = 10$, 10^3 for $x = 13$, etc.). The magnitude of this largest individual term consumes the available precision and, as a result, leaves little or none left for the ever-diminishing net sum that constitutes the desired integral.

Literally, the use of eqn (5), even with (32-bit) double precision, does not permit the exponential integral to be evaluated to three places for $x > 14$ in any case, and with the situation worsening for lesser precision. For these reasons, the use of eqn (5) to evaluate the exponential integral numerically for large x is wholly unsuitable.

$$E_1(x) = e^{-x} \cdot \frac{1}{x + \frac{1}{1 + \frac{1}{x + \frac{2}{1 + \frac{2}{x + \dots}}}}} \quad (5.6)$$

But as x becomes smaller, the number of terms required for convergence rises quickly. Similar arguments apply for the use of an asymptotic expansion for E_1 , which also converges for large x . As such, the more typical approach employed by handbooks is that of a fit. While some steps are taken to make the fits intelligent (e.g., transformation of variables), the fits are all piecewise over the domain of the integral.

Cody and Thatcher [?] performed what is perhaps the definitive work, with the use of Chebyshev[?, ?] approximations to the exponential integral E_1 . Like others, they fit the integral over a piecewise series of subdomains (three in their case) and provide the fitting parameters necessary to evaluate the function to various required precisions, down to relative errors of 10^{-20} . One of the problems with piecewise fitting over two or more subdomains is that functional value and derivatives of the spliced fits will not, in general, match at the domain transition point, unless special accommodations are made. This sort of discontinuity in functional value and/or slope, curvature, *etc.*, may cause difficulties for some numerical algorithms operating upon the fitted function. Numerical splicing/smoothing algorithms aimed at eliminating discontinuities in the value and/or derivatives of a piecewise fit are not, in general, computationally insignificant. Problems associated with piecewise splicing of fits may also be obviated by obtaining an accurate enough fit, such that the error is on the order of magnitude of the limiting machine precision. This alternative, however, requires the use of additional fitting parameters to acquire the improved precision. Thus, regardless of approach, the desire to eliminate discontinuities in the function and its derivatives, between piecewise splices, requires extra computational effort. One final benefit to be had by avoiding the use of piecewise fits is the concomitant avoidance of conditional (*i.e.*, IF...THEN) programming statements in the coding of the routine. The use of conditional statements can preclude maximum computing efficiency on certain parallel computing architectures.

Segletes constructs an analytic, non-piecewise fit to the Exponential Integral but the precision is on the order of 4 decimal places and is not sufficient to compare against the Abramowitz and Stegun Handbook.

Instead we have chosen to use a two piece fitting function based on the Cheby-

shev polynomial for computing E_1 . This agrees with the handbook values to almost the last published digit. See the `e1.input` pamphlet for regression testing against the handbook tables.

5.16.3 E1:R→OPR

The special function E1 below was originally derived from a function written by T.Haavie as the `expint.c` function in the Numlibc library by Lars Erik Lund. Haavie approximates the E1 function by two Chebyshev polynomials. For the range $-4 < x < 4$ the Chebyshev coefficients are:

```
7.8737715392882774, -8.0314874286705335, 3.8797325768522250,
-1.6042971072992259, 0.5630905453891458, -0.1704423017433357,
0.0452099390015415, -0.0106538986439085, 0.0022562638123478,
-0.0004335700473221, 0.0000762166811878, -0.0000123417443064,
0.0000018519745698, -0.0000002588698662, 0.0000000338604319,
-0.0000000041611418, 0.000000004821606, -0.000000000528465,
0.0000000000054945, -0.0000000000005433, 0.0000000000000512,
-0.0000000000000046, 0.0000000000000004
```

and for the range $x > 4$ the Chebyshev coefficients are:

```
0.2155283776715125, 0.1028106215227030, -0.0045526707131788,
0.0003571613122851, -0.0000379341616932, 0.0000049143944914,
-0.0000007355024922, 0.0000001230603606, -0.0000000225236907,
0.0000000044412375, -0.0000000009328509, 0.0000000002069297,
-0.0000000000481502, 0.0000000000116891, -0.0000000000029474,
0.0000000000007691, -0.0000000000002070, 0.0000000000000573,
-0.0000000000000163, 0.0000000000000047, -0.0000000000000014,
0.0000000000000004, -0.0000000000000001
```

I've rewritten the polynomial to use precomputed coefficients that take into account the scaling used by Haavie. I've also rewritten the polynomial using Horner's method so the large powers of x are only computed once.

The result can be either a double float or, or if the argument is zero, infinity. Thus we need to extend the result to be a one-point completion to include infinity.

5.16.5 The Ei Function

This function is based on Kin L. Lee's work[?]. See also [?].

5.16.6 Abstract

The exponential integral $Ei(x)$ is evaluated via Chebyshev series expansion of its associated functions to achieve high relative accuracy throughout the entire real line. The Chebyshev coefficients for these functions are given to 30 significant digits. Clenshaw's[?] method is modified to furnish an efficient procedure for the accurate solution of linear systems having near-triangular coefficient matrices.

5.16.7 Introduction

The evaluation of the exponential integral

$$Ei(x) = \int_{-\infty}^x \frac{e^u}{u} du = -E_1(-x), x \neq 0 \quad (5.7)$$

is usually based on the value of its associated functions, for example, $xe^{-x}Ei(x)$. High accuracy tabulations of integral (1) by means of Taylor series techniques are given by Harris [?] and Miller and Hurst [?]. The evaluation of $Ei(x)$ for $-4 \leq x \leq \infty$ by means of Chebyshev series is provided by Clenshaw [?] to have the absolute accuracy of 20 decimal places. The evaluation of the same integral (1) by rational approximation of its associated functions is furnished by Cody and Thacher [?, ?] for $-\infty < x < \infty$, and has the relative accuracy of 17 significant figures.

The approximation of Cody and Thacher from the point of view of efficient function evaluation are preferable to those of Clenshaw. However, the accuracy of the latter's procedure, unlike those of the former, is not limited by the accuracy or the availability of a master function, which is a means of explicitly evaluating the function in question.

In this paper $Ei(x)$ (or equivalently $-E_1(-x)$) for the entire real line is evaluated via Chebyshev series expansion of its associated functions that are accurate to 30 significant figures by a modification of Clenshaw's procedure. To verify the accuracy of the several Chebyshev series, values of the associated functions were checked against those computed by Taylor series and those of Murnaghan and Wrench [?] (see Remarks on Convergence and Accuracy).

Although for most purposes fewer than 30 figures of accuracy are required, such high accuracy is desirable for the following reasons. In order to further reduce the number of arithmetical operations in the evaluation of a function, the Chebyshev series in question can either be converted into a rational function or rearranged into an ordinary polynomial. Since several figures may be lost in either of these procedures, it is necessary to provide the Chebyshev series

with a sufficient number of figures to achieve the desired accuracy. Furthermore, general function approximation routines, such as those used for minimax rational function approximations, require the explicit evaluation of the function to be approximated. To take account of the errors committed by these routines, the function values must have an accuracy higher than the approximation to be determined. Consequently, high-precision results are useful as a master function for finding approximations for (or involving) $Ei(x)$ (e.g. $[?, ?]$) where prescribed accuracy is less than 30 figures.

5.16.8 Discussion

It is proposed here to provide for the evaluation of $Ei(x)$ by obtaining Chebyshev coefficients for the associated functions given by table 1.

Table 1: Associated Functions of $Ei(x)$ and their ranges of Chebyshev Series Expansions

	Associated function	Range of expansion
Ei1	$xe^{-x} Ei(x)$	$-\infty < x \leq -10$
Ei2	$xe^{-x} Ei(x)$	$-10 \leq x \leq -4$
Ei3	$\frac{Ei(x) - \log x - \gamma}{x}$	$-4 \leq x \leq d42$
Ei4	$xe^{-x} Ei(x)$	$4 \leq x \leq 12$
Ei5	$xe^{-x} Ei(x)$	$12 \leq x \leq 32$
Ei6	$xe^{-x} Ei(x)$	$32 \leq x < \infty$

($\gamma = 0.5772156649\dots$ is Euler's constant.)

(package DFSFUN DoubleFloatSpecialFunctions)+≡

```

Ei(y:OPR):OPR ==
  infinite? y => 1
  x:=retract(y)
  x < -10.0::R =>
    ei:=retract(Ei1(y))
    (ei/(x*exp(-x))):OPR
  x < -4.0::R =>
    ei:=retract(Ei2(y))
    (ei/(x*exp(-x))):OPR
  x < 4.0::R =>
    ei3:=retract(Ei3(y))
    gamma:=0.577215664901532860606512090082::R
    (ei3*x+log(abs(x))+gamma):OPR
  x < 12.0::R =>
    ei:=retract(Ei4(y))
    (ei/(x*exp(-x))):OPR
  x < 32.0::R =>
    ei:=retract(Ei5(y))
    (ei/(x*exp(-x))):OPR

```

```
ei:R:=retract(Ei6(y))
(ei/(x*exp(-x)))::OPR
```

Note that the functions $[Ei(x) - \log|x| - \gamma]/x$ and $xe^{-x}Ei(x)$ have the limiting values of unity at the origin and at infinity, respectively, and that the range of the associated function values is close to unity (see table 4). This makes for the evaluation of the associated functions over the indicated ranges in table 1 (and thus $Ei(x)$ over the entire real line) with high relative accuracy by means of the Chebyshev series. The reason for this will become apparent later.

Some remarks about the choice of the intervals of expansion for the several Chebyshev series are in order here. The partition of the real line indicated by table 1 is chosen to allow for the approximation of the associated functions with a maximum error of 0.5×10^{-30} by polynomials of degree < 50 . The real line has also been partitioned with the objective of providing the interval about zero with the lowest degree of polynomial approximation of the six intervals. This should compensate for the computation of $\log|x|$ required in the evaluation of $Ei(x)$ over that interval. The ranges $-\infty < x \leq -4$ and $4 \leq x < \infty$ are partitioned into 2 and 3 intervals, respectively, to provide approximations to $xe^{-x}Ei(x)$ by polynomials of about the same degree.

5.16.9 Expansions in Chebyshev Series

Let $\phi(t)$ be a differentiable function defined on $[-1,1]$. To facilitate discussion, denote its Chebyshev series and that of its derivative by

$$\phi(t) = \sum_{k=0}^{\infty} {}' A_k^{(0)} T_k(t) \quad \phi'(t) = \sum_{k=0}^{\infty} {}' A_k^{(1)} T_k(t) \quad (5.8)$$

where $T_k(t)$ are Chebyshev polynomials defined by

$$T_k(t) = \cos(k \arccos t), \quad -1 \leq t \leq 1 \quad (5.9)$$

(A prime over a summation sign indicates that the first term is to be halved.)

If $\phi(t)$ and $\phi'(t)$ are continuous, the Chebyshev coefficients $A_k^{(0)}$ and $A_k^{(1)}$ can be obtained analytically (if possible) or by numerical quadrature. However, since each function in table 1 satisfies a linear differential equation with polynomial coefficients, the Chebyshev coefficients can be more readily evaluated by the method of Clenshaw [?].

There are several variations of Clenshaw's procedure (see, e.g. [?]), but for high-precision computation, where multiple precision arithmetic is employed, we find his original procedure easiest to implement. However, straightforward application of it may result in a loss of accuracy if the trial solutions selected are not sufficiently independent. How the difficulty is overcome will be pointed out subsequently.

5.16.10 The function $xe^{-x}Ei(x)$ on the Finite Interval

We consider first the Chebyshev series expansion of

$$f(x) = xe^{-x}Ei(x), \quad (a \leq x \leq b) \quad (5.10)$$

with $x \neq 0$. One can easily verify that after the change of variables

$$x = [(b-a)T + a + b]/2, \quad (-1 \leq t \leq 1) \quad (5.11)$$

the function

$$\phi(t) = f \left[\frac{(b-a)t + a + b}{2} \right] = f(x) \quad (5.12)$$

satisfies the differential equation

$$2(pt + q)\phi'(t) + p(pt + q - 2)\phi(t) = p(pt + q) \quad (5.13)$$

with¹

$$\phi(-1) = ae^{-a}Ei(a) \quad (5.14)$$

where $p = b - a$ and $q = b + a$. Replacing $\phi(t)$ and $\phi'(t)$ in equations 7 by their Chebyshev series, we obtain

$$\sum_{k=0}^{\infty} '(-1)^k A_k^{(0)} = \phi(-1) \quad (5.15)$$

$$2 \sum_{k=0}^{\infty} 'A_k^{(1)}(pt + q)T_k(t) + p \sum_{k=0}^{\infty} 'A_k^{(0)}(pt + q - 2)T_k(t) = p(pt + q) \quad (5.16)$$

It can be demonstrated that if B_k are the Chebyshev coefficients of a function $\Psi(t)$, then C_k , the Chebyshev coefficients of $t^r \Psi(t)$ for positive integers r , are given by [?]

$$C_k = 2^{-r} \sum_{i=0}^r \binom{r}{i} B_{|k-r+2i|} \quad (5.17)$$

Consequently, the left member of equation 15 can be rearranged into a single series involving $T_k(t)$. The comparison of the coefficients of $T_k(t)$ that yields the infinite system of equations

$$\left. \begin{aligned} & \sum_{k=0}^{\infty} '(-1)^k A_k^{(0)} = \phi(-1) \\ & 2pA_{|k-1|}^{(1)} + 4qA_k^{(1)} + 2pA_{k+1}^{(1)} + p^2A_{|k-1|}^{(0)} + 2p(q-2)A_k^{(0)} + p^2A_{k+1}^{(0)} \\ & = \begin{cases} 4pq & , \quad k = 0 \\ 2p^2 & , \quad k = 1 \\ 0 & , \quad k = 2, 3, \dots \end{cases} \end{aligned} \right\} \quad (5.18)$$

¹The value of $Ei(a)$ may be evaluated by means of the Taylor series. In this report $Ei(a)$ is computed by first finding the Chebyshev series approximation to $[Ei(x) - \log|x| - \gamma]/x$ to get $Ei(a)$. The quantities e^a and $\log|a|$ for integral values of a may be found in existing tables

The relation [?]

$$2kA_k^{(0)} = A_{k-1}^{(1)} - A_{k+1}^{(1)} \quad (5.19)$$

can be used to reduce equation 18 to a system of equations involving only $A_k^{(0)}$. Thus, replacing k of equations 18 by $k+2$ and subtracting the resulting equation from equations 18, we have, by means of equation 19, the system of equations

$$\left. \begin{aligned} \sum_{k=0}^{\infty} '(-1)^k A_k^{(0)} &= \phi(-1) \\ 2p(q-2)A_0 + (8q+p^2)A_1 + 2p(6-q)A_2 - p^2A_3 &= 4pq \\ p^2A_{k-1} + 2p(2k+q-2)A_k + 8q(k+1)A_{k+1} + 2p(2k-q+6)A_{k+2} - p^2A_{k+3} \\ &= \begin{cases} 2p^2 & , \quad k=1 \\ 0 & , \quad k=2,3,\dots \end{cases} \end{aligned} \right\} \quad (5.20)$$

The superscript of $A_k^{(0)}$ is dropped for simplicity. In order to solve the infinite system 20, Clenshaw [?] essentially considered the required solution as the limiting solution of the sequence of truncated systems consisting of the first $M+1$ equations of the same system, that is, the solution of the system

$$\sum_{k=0}^M '(-1)^k A_k = \phi(-1) \quad (5.21)$$

$$\left. \begin{aligned} 2p(q-2)A_0 + (8q+p^2)A_1 + 2p(q-6)A_2 - p^2A_3 &= 4pq \quad (5.22) \\ p^2A_{k-1} + 2p(2k+q-2)A_k + 8q(k+1)A_{k+1} + 2p(2k-q+6)A_{k+2} - p^2A_{k+3} \\ &= \begin{cases} 2p^2 & , \quad k=1 \\ 0 & , \quad k=2,3,\dots,M-3 \end{cases} \\ p^2A_{M-3} + 2p(2M+q-6)A_{M-2} + 8q(M-1)A_{M-1} + 2p(2M+4-q)A_M &= 0 \\ p^2A_{M-2} + 2p(2M+q-4)A_{M-1} + 8qMA_M &= 0 \end{aligned} \right\} \quad (5.23)$$

where A_k is assumed to vanish for $K \geq M+1$. To solve system (21,22,23) consider first the subsystem 23 consisting of $M-2$ equations in M unknowns. Here use is made of the fact that the subsystem 23 is satisfied by

$$A_k = c_1\alpha_k + c_2\beta_k + \gamma_k \quad (k=0,1,2,\dots) \quad (5.24)$$

for arbitrary constants c_1 and c_2 , where γ_k is a particular solution of 23 and where α_k and β_k are two independent solutions of the homogeneous equations (23 with $2p^2$ deleted) of the same subsystem. Hence, if α_k , β_k , and γ_k are available, the solution of system (21,22,23) reduces to the determinant of c_1 and c_2 from equations 21 and 22.

To solve equations (21,22,23), we note that

$$\gamma_0 = 2, \quad \gamma_k = 0, \quad \text{for } k = 1(1)M \quad (5.25)$$

is obviously a particular solution of equation 23. The two independent solutions γ_k and β_k of the homogeneous equations of the same subsystem can be generated in turn by backward recurrence if we set

$$\text{and} \quad \left. \begin{array}{l} \alpha_{M-1} = 0, \quad \alpha_M = 1 \\ \beta_{M-1} = 1, \quad \beta_M = 0 \end{array} \right\} \quad (5.26)$$

or choose any α_{M-1} , α_M , and β_{M-1} , β_M for which $\alpha_{M-1}\beta_M - \alpha_M\beta_{M-1} \neq 0$. The arbitrary constants c_1 and c_2 are determined, and consequently the solution of equations (21,22,23) if equation 24 is substituted into equation 21 and 22 and the resulting equations

$$c_1 R(\alpha) + c_2 R(\beta) = \phi(-1) - 1 \quad (5.27)$$

$$c_1 S(\alpha) + c_2 S(\beta) = 8p \quad (5.28)$$

are solved as two equations in two unknowns. The terms $R(\alpha)$ and $S(\alpha)$ are equal, respectively, to the left members of equations 21 and 22 corresponding to solution α_k . (The identical designation holds for $R(\beta)$ and $S(\beta)$.)

The quantities α_k and β_k are known as trial solutions in reference [?]. Clenshaw has pointed out that if α_k and β_k are not sufficiently independent, loss of significance will occur in the formation of the linear combination 24, with consequent loss of accuracy. Clenshaw suggested the Gauss-Seidel iteration procedure to improve the accuracy of the solution. However, this requires the application of an additional computing procedure and may prove to be extremely slow. A simpler procedure which does not alter the basic computing scheme given above is proposed here. The loss of accuracy can effectively be regained if we first generate a third trial solution δ_k ($k=0,1,\dots,M$), where δ_{M-1} and δ_M are equal to $c_1\alpha_{M-1} + c_2\beta_{M-1}$ and $c_1\alpha_M + c_2\beta_M$, respectively, and where δ_k ($k=M-2, M-3, \dots, 0$) is determined using backward recurrence as before by means of equation 23. Then either α_k or β_k is replaced by δ_k and a new set of c_1 and c_2 is determined by equations 27 and 28. Such a procedure can be repeated until the required accuracy is reached. However, only one application of it was necessary in the computation of the coefficients of this report.

As an example, consider the case for $4 \leq x \leq 12$ with $M = 15$. The right member of equation 27 and of equation 28 assume, respectively, the values of 0.43820800 and 64. The trial solutions α_k and β_k generated with $\alpha_{14} = 8$, $\alpha_{15} = 9$ and $\beta_{14} = 7$, $\beta_{15} = 8$ are certainly independent, since $\alpha_{14}\beta_{15} - \alpha_{15}\beta_{14} = 1 \neq 0$. A check of table 2 shows that equations 27 and 28 have, respectively, the residuals of -0.137×10^{-4} and -0.976×10^{-3} . The same table also shows that $c_1\alpha_k$ is opposite in sign but nearly equal in magnitude to $c_2\beta_k$. Cancellations in the formation of the linear combination 24 causes a loss of significance of

2 to 6 figures in the computed A_k . In the second iteration, where a new set of β_k is generated replacing β_{14} and β_{15} , respectively, by $c_1\alpha_{14} + c_2\beta_{14}$ and $c_1\alpha_{15} + c_2\beta_{15}$ of the first iteration, the new $c_1\alpha_k$ and $c_2\beta_k$ differed from 2 to 5 orders of magnitude. Consequently, no cancellation of significant figures in the computation of A_k occurred. Notice that equations 27 and 28 are now satisfied exactly. Further note that the new c_1 and c_2 are near zero and unity, respectively, for the reason that if equations 21, 22, and 23 are satisfied by equation 24 exactly in the first iteration, the new c_1 and c_2 should have the precise values zero and 1, respectively. The results of the third iteration show that the A_k of the second iteration are already accurate to eight decimal places, since the A_k in the two iterations differ in less than 0.5×10^{-8} . Notice that for the third iteration, equations 27 and 28 are also satisfied exactly and that $c_1 = 1$ and $c_2 = 0$ (relative to 8 places of accuracy).

\end{aligned}$$

It is worth noting that the coefficient matrix of system (21,22,23) yields an upper triangular matrix of order $M - 1$ after the deletion of the first two rows and the last two columns. Consequently, the procedure of this section is applicable to any linear system having this property. As a matter of fact, the same procedure can be generalized to solve linear systems having coefficient matrices of order N , the deletion of whose first r ($r < N$) rows and last r columns yields upper triangular matrices of order $N - r$.

5.16.11 The Function $(1/x)[Ei(x) - \log|x| - \gamma]$

Let

$$f(x) = (1/x)[Ei(x) - \log|x| - \gamma], \quad g(x) = e^x, \quad |x| \leq b \quad (5.29)$$

These functions, with the change of variable $x = bt$, simultaneously satisfy the differential equations

$$bt^2\phi'(t) + bt\phi(t) - \psi(t) = -1 \quad (5.30)$$

$$\psi'(t) - b\psi(t) = 0, \quad -1 \leq t \leq 1 \quad (5.31)$$

Conversely,² any solution of equations 30 and 31 is equal to the functions given by equations 29 for the change of variable $x = bt$. Therefore, boundary conditions need not be imposed for the solution of the differential equations.

A procedure similar to that of the previous section gives the coupled infinite recurrence relations

$$bA_1 + bA_3 - B_0 + B_2 = -2 \quad (5.32)$$

$$\left. \begin{aligned} kbA_{k-1} + 2(k+1)bA_{k+1} + (k+2)bA_{k+3} - 2B_k + 2B_{k+2} &= 0 \\ bB_{k-1} - 2kB_k - bB_{k+1} &= 0, \quad k = 1, 2, \dots \end{aligned} \right\} \quad (5.33)$$

where A_k and B_k are the Chebyshev coefficients of $\phi(t)$ and $\psi(t)$, respectively.

Consider first the subsystem 33. If $A_k = \alpha_k$ and $B_k = \beta_k$ are a simultaneous solution of the system, which is homogeneous, then

$$\text{and} \quad \left. \begin{aligned} A_k &= c\alpha_k \\ B_k &= c\beta_k \end{aligned} \right\} \quad (5.34)$$

²The general solution of the differential equations has the form

$$\begin{aligned}
\phi(t) &= (c_1/t) + [Ei(bt) - \log|bt| - \gamma]/bt \\
\psi(t) &= c_2e^{bt}
\end{aligned}$$

where the first and second terms of $\phi(t)$ are, respectively, the complementary solution and a particular integral of equation 30. The requirement that $\phi(t)$ is bounded makes the constant $c_1 = 0$. The fact that $\psi(0) = 1$ is implicit in equation 30.

are also a solution for an arbitrary constant c . Thus based on considerations analogous to the solution of equations 21, 22, and 23, one can initiate an approximate solution of equations 32 and 33 by setting

$$\left. \begin{aligned} \alpha_M = 0, \quad \alpha_k = 0 \quad \text{for } k \geq M+1 \\ \beta_M = 1, \quad \beta_k = 0 \quad \text{for } k \geq M+1 \end{aligned} \right\} \quad (5.35)$$

and then determining α_k and β_k ($k = M-1, M-2, \dots, 0$) by backward recurrence by means of equation 33. The arbitrary constant c is determined by substituting 34 into 32.

5.16.12 The Function $xe^{-x}Ei(x)$ on the Infinite Interval

Let

$$f(x) = xe^{-x}Ei(x), \quad -\infty < x \leq b < 0, \quad \text{or } 0 < b \leq x < \infty \quad (5.36)$$

By making the change of variables,

$$x = 2b/(t+1) \quad (5.37)$$

we can easily demonstrate that

$$f(x) = f[2b/(t+1)] = \phi(t) \quad (5.38)$$

satisfies the differential equation

$$(t+1)^2\phi'(t) + (t+1-2b)\phi(t) = -2b \quad (5.39)$$

with

$$\phi(1) = be^{-b}Ei(b) \quad (5.40)$$

An infinite system of equations involving the Chebyshev coefficients A_k of $\phi(t)$ is deducible from equations 39 and 40 by the same procedure as applied to equations 13 and 14 to obtain the infinite system 20; it is given as follows.

$$\sum_{k=0}^{\infty} ' A_k = \phi(1) = be^{-b}Ei(b) \quad (5.41)$$

$$(1-2b)A_0 + 3A_1 + (3+2b)A_2 + A_3 = -4b \quad (5.42)$$

$$\begin{aligned} kA_{k-1} + 2[(2k+1)-2b]A_k + 6(k+1)A_{k+1} + 2(2k+3+2b)A_{k+2} \\ + (k+2)A_{k+3} = 0, \quad k = 1, 2, \dots \end{aligned} \quad (5.43)$$

As in the case of equations 21, 22 and 23, the solution of 41, 42 and 43 can be assumed to be

$$A_k = c_1\alpha_k + c_2\beta_k \quad (5.44)$$

with A_k vanishing for a $k \geq M$. Thus, we can set, say

$$\left. \begin{array}{l} \alpha_{M-1} = 0 \quad , \quad \alpha_M = 1 \\ \beta_{M-1} = 1 \quad , \quad \beta_M = 0 \end{array} \right\} \quad (5.45)$$

and determine the trial solutions α_k and β_k ($k=M-1, M-2, \dots, 0$) by means of equation 43 by backward recurrence. The required solution of equations 41, 42, and 43 is then determined by substituting equation 44 in equations 41 and 42 and solving the resulting equations for c_1 and c_2 .

Loss of accuracy in the computation of A_k can also occur here, as in the solution of equations 21, 22 and 23, if the trial solutions are not sufficiently independent. The process used to improve the accuracy of A_k of the system 21, 22 and 23 can also be applied here.

For efficiency in computation, it is worth noting that for $b < 0$ ($-\infty < x \leq b < 0$) the boundary condition 40 is not required for the solution of equation 39 and 40. This follows from the fact that any solution³ of the differential equation 39 is equal to $xe^{-x}Ei(x)$ ($x = 2b/(t+1)$). Hence the A_k of $xe^{-x}Ei(x)$ for $-\infty < x \leq b < 0$ can be obtained without the use of equation 39 and can be assumed to have the form

$$A_k = c\alpha_k, \quad (k = 0, 1, \dots, M) \quad (5.46)$$

The $M+1$ values of α_k can be generated by setting $\alpha_M = 1$ and computing α_k ($k=0, 1, \dots, M-1$) by means of equation 43 by backward recurrence. The substitution of equation 46 into 42 then enables one to determine c from the resulting equation.

5.16.13 Remarks on Convergence and Accuracy

The Chebyshev coefficients of table 3 were computed on the IBM 7094 with 50-digit normalized floating-point arithmetic. In order to assure that the sequence of approximate solutions (see Discussion) converged to the limiting solution of the differential equation in question, a trial M was incremented by 4 until the approximate Chebyshev coefficients showed no change greater than or equal to 0.5×10^{-35} . Hence the maximum error is bounded by

$$0.5(M+1) \times 10^{-35} + \sum_{M+1}^{\infty} |A_k| \quad (5.47)$$

where the first term is the maximum error of the $M+1$ approximate Chebyshev coefficients, and the sum is the maximum error of the truncated Chebyshev series

³The general solution of the differential equation 39. Since equation 39 has no bounded complementary solution for $-\infty < x \leq b < 0$, every solution of it is equal to the particular integral $xe^{-x}Ei(x)$. On the other hand, a solution of equation 39 for $0 < x \leq b < \infty$ would, in general, involve the complementary function. Hence, boundary condition 40 is required to guarantee that the solution of equation 39 is equal to $xe^{-x}Ei(x)$.

of $M+1$ terms. If the Chebyshev series is rapidly convergent, the maximum error of the approximate Chebyshev series should be of the order of 10^{-30} . The coefficients of table 3 have been rounded to 30 digits, and higher terms for $k > N$ giving the maximum residual

$$\sum_{k=N+1}^M |A_k| < 0.5 \times 10^{-30} \quad (5.48)$$

have been dropped. This should allow for evaluation of the relevant function that is accurate to 30 decimal places. Since the range of values of each function is bounded between $2/5$ and 5 , the evaluated function should be good to 30 significant digits. Taylor series evaluation also checks with that of the function values of table 4 (computed with 30-digit floating-point arithmetic using the coefficients of table 3) for at least $28\frac{1}{2}$ significant digits. Evaluation of $Ei(x)$ using the coefficients of table 3 also checked with Murnaghan and Wrench [?] for $28\frac{1}{2}$ significant figures.

Table 3: Chebyshev Coefficients (a)

$$xe^{-x} Ei(x) = \sum_{k=0}^{40} 'A_k T_k(t), \quad t = (-20/x) - 1, \quad (-\infty < x \leq -10)$$

DrawComplex(): Exports == Implementation where

Exports == with

drawComplex: (C -> C,S,S,Boolean) -> VIEW3D

++ drawComplex(f,rRange,iRange,arrows?)

++ draws a complex function as a height field.

++ It uses the complex norm as the height and the complex
++ argument as the color.

++ It will optionally draw arrows on the surface indicating the direction
++ of the complex value.\newline

++ Sample call:

++ \spad{f z == exp(1/z)}

++ \spad{drawComplex(f, 0.3..3, 0..2*%pi, false)}

++ Parameter descriptions:

++ f: the function to draw

++ rRange : the range of the real values

```

++ iRange : the range of imaginary values
++ arrows? : a flag indicating whether to draw the phase arrows for f
++ Call the functions \axiomFunFrom{setRealSteps}{DrawComplex} and
++ \axiomFunFrom{setImagSteps}{DrawComplex} to change the
++ number of steps used in each direction.
drawComplexVectorField: (C -> C,S,S) -> VIEW3D
++ drawComplexVectorField(f,rRange,iRange)
++ Draws a complex vector field using arrows on the \spad{x--y} plane.
++ These vector fields should be viewed from the top by pressing the
++ "XY" translate button on the 3-d viewport control panel.\newline
++ Sample call:
++ \spad{f z == sin z}
++ \spad{drawComplexVectorField(f, -2..2, -2..2)}
++ Parameter descriptions:
++ f : the function to draw
++ rRange : the range of the real values
++ iRange : the range of the imaginary values
++ Call the functions \axiomFunFrom{setRealSteps}{DrawComplex} and
++ \axiomFunFrom{setImagSteps}{DrawComplex} to change the
++ number of steps used in each direction.
setRealSteps: INT -> INT
++ setRealSteps(i)
++ sets to i the number of steps to use in the real direction
++ when drawing complex functions. Returns i.
setImagSteps: INT -> INT
++ setImagSteps(i)
++ sets to i the number of steps to use in the imaginary direction
++ when drawing complex functions. Returns i.
setClipValue: SF-> SF
++ setClipValue(x)
++ sets to x the maximum value to plot when drawing complex functions. Returns x.

++ AMS Classifications:
++ Keywords:
++ References:
++ Description: Hack for the draw interface. DrawNumericHack provides
++ a "coercion" from something of the form \spad{x = a..b} where \spad{a}
++ and b are
++ formal expressions to a binding of the form \spad{x = c..d} where c and d
++ are the numerical values of \spad{a} and b. This "coercion" fails if
++ \spad{a} and b contains symbolic variables, but is meant for expressions
++ involving %pi.
++ NOTE: This is meant for internal use only.
```

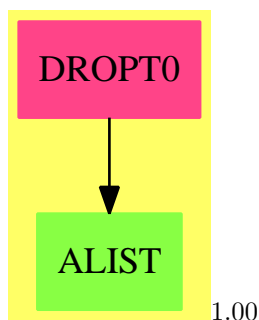

```
DrawNumericHack(R:Join(OrderedSet,IntegralDomain,ConvertibleTo Float)):
with coerce: SegmentBinding Expression R -> SegmentBinding Float
    ++ coerce(x = a..b) returns \spad{x = c..d} where c and d are the
    ++ numerical values of \spad{a} and b.

  combineFeatureCompatibility: (F,LF) -> F
    ++ combineFeatureCompatibility(C1,L) is for interacting attributes
  sparsityIF: MEDF -> F
    ++ sparsityIF(m) calculates the sparsity of a jacobian matrix
  jacobian: (VEDF,LS) -> MEDF
    ++ jacobian(v,w) is a local function to make a jacobian matrix
  eval: (MEDF,LS,VEDF) -> MEDF
    ++ eval(mat,symbols,values) evaluates a multivariable matrix at given values
    ++ for each of a list of variables
  stiffnessAndStabilityFactor: MEDF -> RSS
    ++ stiffnessAndStabilityFactor(me) calculates the stability and
    ++ stiffness factor of a system of first-order differential equations
    ++ (by evaluating the maximum difference in the real parts of the
    ++ negative eigenvalues of the jacobian of the system for which 0(10)
    ++ equates to mildly stiff whereas stiffness ratios of 0(10^6) are not
    ++ uncommon) and whether the system is likely to show any oscillations
    ++ (identified by the closeness to the imaginary axis of the complex
    ++ eigenvalues of the jacobian).
  stiffnessAndStabilityOfODEIF:ODEA -> RSS
    ++ stiffnessAndStabilityOfODEIF(ode) calculates the intensity values
    ++ of stiffness of a system of first-order differential equations
    ++ (by evaluating the maximum difference in the real parts of the
    ++ negative eigenvalues of the jacobian of the system for which 0(10)
    ++ equates to mildly stiff whereas stiffness ratios of 0(10^6) are not
    ++ uncommon) and whether the system is likely to show any oscillations
    ++ (identified by the closeness to the imaginary axis of the complex
    ++ eigenvalues of the jacobian).
    ++
    ++ It returns two values in the range [0,1].
  systemSizeIF:ODEA -> F
    ++ systemSizeIF(ode) returns the intensity value of the size of
    ++ the system of ODEs. 20 equations corresponds to the neutral
    ++ value. It returns a value in the range [0,1].
  expenseOfEvaluationIF:ODEA -> F
    ++ expenseOfEvaluationIF(o) returns the intensity value of the

```

```

++ cost of evaluating the input ODE. This is in terms of the number
++ of ‘‘operational units’’. It returns a value in the range
++ [0,1].\newline\indent{20}
++ 400 ‘‘operation units’’ -> 0.75 \newline
++ 200 ‘‘operation units’’ -> 0.5 \newline
++ 83 ‘‘operation units’’ -> 0.25 \newline\indent{15}
++ exponentiation = 4 units , function calls = 10 units.
accuracyIF:ODEA -> F
++ accuracyIF(o) returns the intensity value of the accuracy
++ requirements of the input ODE. A request of accuracy of  $10^{-6}$ 
++ corresponds to the neutral intensity. It returns a value
++ in the range [0,1].
intermediateResultsIF:ODEA -> F
++ intermediateResultsIF(o) returns a value corresponding to the
++ required number of intermediate results required and, therefore,
++ an indication of how much this would affect the step-length of the
++ calculation. It returns a value in the range [0,1].

```

```

++ Description:
++ This is a package for the exact computation of eigenvalues and eigenvectors.
++ This package can be made to work for matrices with coefficients which are
++ rational functions over a ring where we can factor polynomials.
++ Rational eigenvalues are always explicitly computed while the
++ non-rational ones are expressed in terms of their minimal
++ polynomial.
-- Functions for the numeric computation of eigenvalues and eigenvectors
-- are in numeigen spad.
EigenPackage(R) : C == T
where
  R      : GcdDomain
  P      ==> Polynomial R
  F      ==> Fraction P
  SE     ==> Symbol()
  SUP    ==> SparseUnivariatePolynomial(P)
  SUF    ==> SparseUnivariatePolynomial(F)
  M      ==> Matrix(F)
  NNI    ==> NonNegativeInteger
  ST     ==> SuchThat(SE,P)

Eigenvalue ==> Union(F,ST)
EigenForm  ==> Record(eigval:Eigenvalue,eigmult:NNI,eigvec : List M)
GenEigen   ==> Record(eigval:Eigenvalue,geneigvec:List M)

C == with
characteristicPolynomial : (M,Symbol) -> P
  ++ characteristicPolynomial(m,var) returns the
  ++ characteristicPolynomial of the matrix m using
  ++ the symbol var as the main variable.

characteristicPolynomial :      M      -> P
  ++ characteristicPolynomial(m) returns the
  ++ characteristicPolynomial of the matrix m using
  ++ a new generated symbol symbol as the main variable.

eigenvalues      :      M      -> List Eigenvalue
  ++ eigenvalues(m) returns the
  ++ eigenvalues of the matrix m which are expressible
  ++ as rational functions over the rational numbers.

eigenvector      :      (Eigenvalue,M) -> List M
  ++ eigenvector(eigval,m) returns the
  ++ eigenvectors belonging to the eigenvalue eigval
  ++ for the matrix m.

```

```

generalizedEigenvector : (Eigenvalue,M,NNI,NNI) -> List M
++ generalizedEigenvector(alpha,m,k,g)
++ returns the generalized eigenvectors
++ of the matrix relative to the eigenvalue alpha.
++ The integers k and g are respectively the algebraic and the
++ geometric multiplicity of the eigenvalue alpha.
++ alpha can be either rational or not.
++ In the second case alpha is the minimal polynomial of the
++ eigenvalue.

generalizedEigenvector : (EigenForm,M) -> List M
++ generalizedEigenvector(eigen,m)
++ returns the generalized eigenvectors
++ of the matrix relative to the eigenvalue eigen, as
++ returned by the function eigenvectors.

generalizedEigenvectors : M -> List GenEigen
++ generalizedEigenvectors(m)
++ returns the generalized eigenvectors
++ of the matrix m.

eigenvectors          : M          -> List(EigenForm)
++ eigenvectors(m) returns the eigenvalues and eigenvectors
++ for the matrix m.
++ The rational eigenvalues and the correspondent eigenvectors
++ are explicitly computed, while the non rational ones
++ are given via their minimal polynomial and the corresponding
++ eigenvectors are expressed in terms of a "generic" root of
++ such a polynomial.

```

Mathematica, Maple, and Maxima give:

$$\frac{3}{(3 * x + 6 * y)^2 \sqrt{1 - \frac{1}{(3 * x + 6 * y)^2}}}$$

which proceeds directly from the formula for the derivative of asec:

$$\frac{d}{dx} \operatorname{arcsec}(x) = \frac{1}{x \sqrt{x^2 - 1}}$$

$\langle \text{ElementaryFunction.input} \rangle + \equiv$

```
--S 16 of 32
D(asec(3*x+6*y),x)
--R
--R
--R
--R
--R (14) -----

```

Mathematica and Maxima return

```
\[-3 csch(3*x+6*y)^2\]
```

Maple returns Axiom's answer. Both are equivalent.

[illegible]

Mathematica and Maple show

$$\frac{3}{\sqrt{-1+3*x+6*y}\sqrt{1+3*x+6*y}}$$

Maxima gives Axiom's answer. Both are equivalent, just factored forms.

$\langle ElementaryFunction.input \rangle + \equiv$

```

```
--R
--E 30
```

Type: Expression Integer

Mathematica gives

$$-\frac{3}{(3x+6y)\sqrt{\frac{1-3x-6y}{1+3x+6y}}(1+3x+6y)}$$

Maxima gives

$$-\frac{3}{(6y+3x)^2\sqrt{\frac{1}{(6y+3x)^2}-1}}$$

Maple gives

$$-\frac{3}{(3x+6y)^2\sqrt{\frac{1}{3x+6y}-1}\sqrt{\frac{1}{3x+6y}+1}}$$

Axiom cannot simplify these differences to zero but Maxima does which shows they are all equivalent answers.

6.5 package DEFINTEF ElementaryFunctionDefiniteIntegration

6.6 ElementaryFunctionDefiniteIntegration

Exports:

innerint integrate integrate

<package DEFINTEF ElementaryFunctionDefiniteIntegration>=

)abbrev package DEFINTEF ElementaryFunctionDefiniteIntegration

++ Definite integration of elementary functions.

++ Author: Manuel Bronstein

++ Date Created: 14 April 1992

++ Date Last Updated: 2 February 1993

++ Description:

++ \spadtype{ElementaryFunctionDefiniteIntegration}

++ provides functions to compute definite

++ integrals of elementary functions.

ElementaryFunctionDefiniteIntegration(R, F): Exports == Implementation where

R : Join(EuclideanDomain, OrderedSet, CharacteristicZero,
RetractableTo Integer, LinearlyExplicitRingOver Integer)

F : Join(TranscendentalFunctionCategory, PrimitiveFunctionCategory,
AlgebraicallyClosedFunctionSpace R)

B ==> Boolean

SE ==> Symbol

Z ==> Integer

P ==> SparseMultivariatePolynomial(R, K)

K ==> Kernel F

UP ==> SparseUnivariatePolynomial F

OFE ==> OrderedCompletion F

U ==> Union(f1:OFE, f2:List OFE, fail:"failed", pole:"potentialPole")

Exports ==> with

integrate: (F, SegmentBinding OFE) -> U

```

++ integrate(f, x = a..b) returns the integral of
++ \spad{f(x)dx} from a to b.
++ Error: if f has a pole for x between a and b.
integrate: (F, SegmentBinding OFE, String) -> U
++ integrate(f, x = a..b, "noPole") returns the
++ integral of \spad{f(x)dx} from a to b.
++ If it is not possible to check whether f has a pole for x
++ between a and b (because of parameters), then this function
++ will assume that f has no such pole.
++ Error: if f has a pole for x between a and b or
++ if the last argument is not "noPole".
innerint: (F, SE, OFE, OFE, B) -> U
++ innerint(f, x, a, b, ignore?) should be local but conditional

(package EFULS ElementaryFunctionsUnivariateLaurentSeries)≡

```

)abbrev package EFULS ElementaryFunctionsUnivariateLaurentSeries
++ This package provides elementary functions on Laurent series.
++ Author: Clifton J. Williamson
++ Date Created: 6 February 1990
++ Date Last Updated: 25 February 1990
++ Keywords: elementary function, Laurent series
++ Examples:
++ References:

```

```

ElementaryFunctionsUnivariateLaurentSeries(Coef,UTS,ULS):_

```

```

Exports == Implementation where

```

```

++ This package provides elementary functions on any Laurent series
++ domain over a field which was constructed from a Taylor series
++ domain. These functions are implemented by calling the
++ corresponding functions on the Taylor series domain. We also
++ provide 'partial functions' which compute transcendental
++ functions of Laurent series when possible and return "failed"

```

```

++ when this is not possible.

      differentiate(t::F, x)::UP))

```

Bug #100 is an infinite loop that eventually kills Axiom from the input

```
integrate((z^a+1)^b,z)
```

Line 2 of this function used to read:

```
symbolIfCan(k := kmax(l := union(l, varselect(kernels g, x))))
```

The loop occurs when the call to union causes

```
      a log(z)
    %e
```

to get added to the list every time. This gives the argument to kmax

```
      a log(z)
arg1= [z,%e      ]
```

and the result being

```
      a log(z)
    %e
```

We keep coming back to process this term, which ends up putting the same term back on the list and we loop. Waldek's solution is to remove the union call.

The original patch fixed the infinite regression mentioned above but caused Axiom to return a closed form of the integral:

```
integrate(asech(x)/x,x)
```

which should not have a closed form. This is referenced in the FriCAS SVN revision 279.

Essentially this new patch uses only logarithms of rational functions when integrating rational functions. It is unclear whether this is the correct fix.

```
<package INTEF ElementaryIntegration>+≡
  lfextendedint(f, x, g) ==
    empty?(l := varselect(kernels f, x)) => [x::F * f, 0]
    symbolIfCan(k := kmax(l))
    case SE =>
      g1 :=
        empty?(l1 := varselect(kernels g,x)) => 0::F
        kmax(l1) = k => g
        0::F
    map((x1:RF):F +-> multivariate(x1, k),
        extendedint(univariate(f, k),
```

```
        univariate(g1, k)))  
is?(k, "exp"::SE) => expextint(f, x, k, g)  
prim?(k, x)      => primextint(f, x, k, g)  
has?(operator k, ALGOP) => alglfextint(f, k, l, x, g)  
unkextint(f, x, g)
```

This is part of the fix for bug 100. Line 2 of this function used to read:

```
symbolIfCan(k := kmax(l := union(l, vark(lu, x)))) case SE =>
```

See the above discussion for why this causes an infinite loop.

```

6.29 package ERROR ErrorFunctions

6.30 ErrorFunctions

Exports:

error

```

(package ERROR ErrorFunctions)≡
)abbrev package ERROR ErrorFunctions
++ Author: Robert S. Sutor
++ Date Created: 29 May 1990
++ Date Last Updated: 29 May 1990
++ Description:
++ ErrorFunctions implements error functions callable from the system
++ interpreter. Typically, these functions would be called in user
++ functions. The simple forms of the functions take one argument
++ which is either a string (an error message) or a list of strings
++ which all together make up a message. The list can contain
++ formatting codes (see below). The more sophisticated versions takes
++ two arguments where the first argument is the name of the function
++ from which the error was invoked and the second argument is either a
++ string or a list of strings, as above. When you use the one
++ argument version in an interpreter function, the system will
++ automatically insert the name of the function as the new first
++ argument. Thus in the user interpreter function
++ \spad{f x == if x < 0 then error "negative argument" else x}
++ the call to error will actually be of the form
++ \spad{error("f","negative argument")}
++ because the interpreter will have created a new first argument.
++
++ Formatting codes: error messages may contain the following
++ formatting codes (they should either start or end a string or
++ else have blanks around them):
++ \spad{%l} start a new line
++ \spad{%b} start printing in a bold font (where available)
  
```

```

++ \spad{%d}      stop printing in a bold font (where available)
++ \spad{%ceon}   start centering message lines
++ \spad{%ceoff}  stop centering message lines
++ \spad{%rjon}   start displaying lines "ragged left"
++ \spad{%rjoff}  stop displaying lines "ragged left"
++ \spad{%i}      indent following lines 3 additional spaces
++ \spad{%u}      unindent following lines 3 additional spaces
++ \spad{%xN}     insert N blanks (eg, \spad{%x10} inserts 10 blanks)
++
++ Examples:
++ 1. \spad{error "Whoops, you made a %l %ceon %b big %d %ceoff %l mistake!"}
++ 2. \spad{error ["Whoops, you made a", "%l %ceon %b", "big",
++              "%d %ceoff %l", "mistake!"]}

```

<EuclideanGroebnerBasisPackage.help>≡

```
=====
euclideanGroebner examples
=====
```

Example to call euclideanGroebner:

```
a1:DMP([y,x],INT):= (9*x**2 + 5*x - 3)+ y*(3*x**2 + 2*x + 1)
a2:DMP([y,x],INT):= (6*x**3 - 2*x**2 - 3*x +3) + y*(2*x**3 - x - 1)
a3:DMP([y,x],INT):= (3*x**3 + 2*x**2) + y*(x**3 + x**2)
an:=[a1,a2,a3]
euclideanGroebner(an)
```

This will return the weak euclidean Groebner basis set.
All reductions are total reductions.

You can get more information by providing a second argument.
To get the reduced critical pairs do:

```
euclideanGroebner(an,"redcrit")
```

You can get other information by calling:

```
euclideanGroebner(an,"info")
```

which returns:

```
ci => Leading monomial for critpair calculation
tci => Number of terms of polynomial i
cj => Leading monomial for critpair calculation
tcj => Number of terms of polynomial j
c => Leading monomial of critpair polynomial
tc => Number of terms of critpair polynomial
rc => Leading monomial of redcritpair polynomial
trc => Number of terms of redcritpair polynomial
tH => Number of polynomials in reduction list H
tD => Number of critpairs still to do
```

The three argument form returns all of the information:

```
euclideanGroebner(an,"info","redcrit")
```

The term ordering is determined by the polynomial type used.
Suggested types include

```
DistributedMultivariatePolynomial
HomogeneousDistributedMultivariatePolynomial
```

`GeneralDistributedMultivariatePolynomial`

++ Date Last Updated: 2-28-91
++ Basic Functions:
++ Related Constructors: Ideal, IdealDecompositionPackage, GroebnerPackage
++ Also See:
++ AMS Classifications:
++ Keywords: groebner basis, polynomial ideal, euclidean domain
++ References:
++ Description: \spadtype{EuclideanGroebnerBasisPackage} computes groebner
++ bases for polynomial ideals over euclidean domains.
++ The basic computation provides
++ a distinguished set of generators for these ideals.
++ This basis allows an easy test for membership: the operation
++ \spadfun{euclideanNormalForm} returns zero on ideal members. The string
++ "info" and "redcrit" can be given as additional args to provide
++ incremental information during the computation. If "info" is given,
++ a computational summary is given for each s-polynomial. If "redcrit"
++ is given, the reduced critical pairs are printed. The term ordering
++ is determined by the polynomial type used. Suggested types include
++ \spadtype{DistributedMultivariatePolynomial},
++ \spadtype{HomogeneousDistributedMultivariatePolynomial},
++ \spadtype{GeneralDistributedMultivariatePolynomial}.

6.47 package EXPRSOL ExpressionSolve

6.47.1 Bugs

```
seriesSolve(sin f x / cos x, f, x, [1])$EXPRSOL(INT, EXPR INT, UFPS EXPR INT, UFPS SUPEXPR EXPR INT)
```

returns

```
((0 . 1) 0 . 1) NonNullStream #<compiled-function |STREAM;generate;M$;62!0|> . UNPRINTABLE)
```

but

```
U ==> UFPS SUPEXPR EXPR INT
```

```
seriesSolve(s +-> sin s *((cos monomial(1,1)$U)**-1)$U, f, x, [0])$EXPRSOL(INT, EXPR INT, UFPS EXPR INT,
```

works. This is probably due to missing “/” in UFPS.

I’d really like to be able to specify a function that works for all domains in a category. For example, $\{x \mapsto y(x)^2 + \sin x + x\}$ should work for $\text{EXPR} \setminus \text{INT}$ as well as for $\text{UTS} \setminus \text{INT}$, both being domains having $\text{TranscendentalFunctionCategory}$.

<implementation: EXPRSOL ExpressionSolve>
```

The general method is to transform the given expression into a form which can then be compiled. There is currently no other way in Axiom to transform an expression into a function.

We need to replace the differentiation operator by the corresponding function in the power series category, and make composition explicit. Furthermore, we need to replace the variable by the corresponding variable in the power series. It turns out that the compiler doesn't find the right definition of monomial(1,1). Thus we introduce it as a second argument. In fact, maybe that's even cleaner. Also, we need to tell the compiler that kernels that are independent of the main variable should be coerced to elements of the coefficient ring, since it will complain otherwise.

I cannot find an example for this behaviour right now. However, if I do use the coerce, the following fails:

```
seriesSolve(h x -1-x*h x *h(q*x), h, x, [1])
```

```
(implementation: EXPRSOL ExpressionSolve)≡
  opelt := operator("elt"::Symbol)$OP
  opdiff := operator("D"::Symbol)$OP
  opcoerce := operator("coerce"::Symbol)$OP

--      replaceDiffs: (F, OP, Symbol) -> F

e04AgentsPackage(): E == I where
E ==> with
  finiteBound:(LOCDF,DF) -> LDF
    ++ finiteBound(l,b) repaces all instances of an infinite entry in
    ++ \axiom{l} by a finite entry \axiom{b} or \axiom{-b}.
  sortConstraints:NOA -> NOA
    ++ sortConstraints(args) uses a simple bubblesort on the list of
    ++ constraints using the degree of the expression on which to sort.
    ++ Of course, it must match the bounds to the constraints.
  sumOfSquares:EDF -> Union(EDF,"failed")
    ++ sumOfSquares(f) returns either an expression for which the square is
    ++ the original function of "failed".
  splitLinear:EDF -> EDF
    ++ splitLinear(f) splits the linear part from an expression which it
    ++ returns.
  simpleBounds?:LEDF -> Boolean
    ++ simpleBounds?(l) returns true if the list of expressions l are
    ++ simple.
  linear?:LEDF -> Boolean
    ++ linear?(l) returns true if all the bounds l are either linear or
    ++ simple.
  linear?:EDF -> Boolean
    ++ linear?(e) tests if \axiom{e} is a linear function.
  linearMatrix:(LEDF, NNI) -> MDF
    ++ linearMatrix(l,n) returns a matrix of coefficients of the linear
    ++ functions in \axiom{l}. If l is empty, the matrix has at least one
    ++ row.
  linearPart:LEDF -> LEDF
    ++ linearPart(l) returns the list of linear functions of \axiom{l}.
  nonLinearPart:LEDF -> LEDF
    ++ nonLinearPart(l) returns the list of non-linear functions of \axiom{l}.
  quadratic?:EDF -> Boolean
    ++ quadratic?(e) tests if \axiom{e} is a quadratic function.
  variables:LSA -> LS
    ++ variables(args) returns the list of variables in \axiom{args.lfn}
  varList:(EDF,NNI) -> LS
    ++ varList(e,n) returns a list of \axiom{n} indexed variables with name
    ++ as in \axiom{e}.
  changeNameToObjf:(Symbol,Result) -> Result
    ++ changeNameToObjf(s,r) changes the name of item \axiom{s} in \axiom{r}
    ++ to objf.
  expenseOfEvaluation:LSA -> F

```

```

++ expenseOfEvaluation(o) returns the intensity value of the
++ cost of evaluating the input set of functions. This is in terms
++ of the number of ‘‘operational units’’. It returns a value
++ in the range [0,1].
optAttributes:Union(noa:NOA,lsa:LSA) -> List String
++ optAttributes(o) is a function for supplying a list of attributes
++ of an optimization problem.

`<FactoredFunctions2.help>≡`

```
=====
FactoredFunctions2 examples
=====
```

The FactoredFunctions2 package implements one operation, map, for applying an operation to every base in a factored object and to the unit.

```
double(x) == x + x
                                     Type: Void
```

```
f := factor(720)
      4 2
      2 3 5
                                     Type: Factored Integer
```

Actually, the map operation used in this example comes from Factored itself, since double takes an integer argument and returns an integer result.

```
map(double,f)
      4 2
      2 4 6 10
                                     Type: Factored Integer
```

If we want to use an operation that returns an object that has a type different from the operation's argument, the map in Factored cannot be used and we use the one in FactoredFunctions2.

```
makePoly(b) == x + b
              4      2
      (x + 1)(x + 2) (x + 3) (x + 5)
                                     Type: Factored Polynomial Integer
```

In fact, the "2" in the name of the package means that we might be using factored objects of two different types.

```
g := map(makePoly,f)
```

It is important to note that both versions of map destroy any information known about the bases (the fact that they are prime, for instance).

The flags for each base are set to "nil" in the object returned by map.

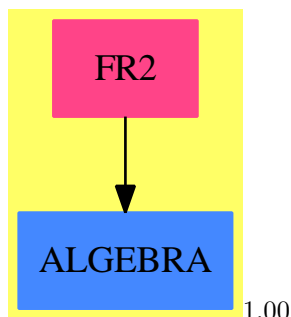

```
nthFlag(g,1)
      "nil"
```

Type: Union("nil",...)

7.4 FactoredFunctions2

Exports:

map

```

(package FR2 FactoredFunctions2)≡
)abbrev package FR2 FactoredFunctions2
++ Author: Robert S. Sutor
++ Date Created: 1987
++ Change History:
++ Basic Operations: map
++ Related Constructors: Factored
++ Also See:
++ AMS Classifications: 11A51, 11Y05
++ Keywords: map, factor
++ References:
++ Description:
++ \spadtype{FactoredFunctions2} contains functions that involve
++ factored objects whose underlying domains may not be the same.
++ For example, \spadfun{map} might be used to coerce an object of
++ type \spadtype{Factored(Integer)} to
++ \spadtype{Factored(Complex(Integer))}.
FactoredFunctions2(R, S): Exports == Implementation where
  R: IntegralDomain
  S: IntegralDomain

Exports ==> with
  map: (R -> S, Factored R) -> Factored S
    ++ map(fn,u) is used to apply the function \userfun{fn} to every
    ++ factor of \spadvar{u}. The new factored object will have all its
    ++ information flags set to "nil". This function is used, for
    ++ example, to coerce every factor base to another type.

Implementation ==> add
  map(func, f) ==
    func(unit f) *
  
```

```

_*/[nilFactor(func(g.factor), g.exponent) for g in factors f]

```

$\langle FR2.dotabb \rangle \equiv$

"FR2" -> "ALGEBRA"

```

7.5 package FRUTIL FactoredFunctionUtilities

7.6 FactoredFunctionUtilities

Exports:

mergeFactors refine

```

<package FRUTIL FactoredFunctionUtilities>≡
)abbrev package FRUTIL FactoredFunctionUtilities
++ Author:
++ Date Created:
++ Change History:
++ Basic Operations: refine, mergeFactors
++ Related Constructors: Factored
++ Also See:
++ AMS Classifications: 11A51, 11Y05
++ Keywords: factor
++ References:
++ Description:
++ \spadtype{FactoredFunctionUtilities} implements some utility
++ functions for manipulating factored objects.
FactoredFunctionUtilities(R): Exports == Implementation where
  R: IntegralDomain
  FR ==> Factored R

Exports ==> with
  refine: (FR, R-> FR) -> FR
    ++ refine(u,fn) is used to apply the function \userfun{fn} to
    ++ each factor of \spadvar{u} and then build a new factored
    ++ object from the results. For example, if \spadvar{u} were
    ++ created by calling \spad{nilFactor(10,2)} then
    ++ \spad{refine(u,factor)} would create a factored object equal
    ++ to that created by \spad{factor(100)} or
    ++ \spad{primeFactor(2,2) * primeFactor(5,2)}.
  
```

```

mergeFactors: (FR,FR) -> FR
  ++ mergeFactors(u,v) is used when the factorizations of \spadvar{u}
  ++ and \spadvar{v} are known to be disjoint, e.g. resulting from a
  ++ content/primitive part split. Essentially, it creates a new
  ++ factored object by multiplying the units together and appending
  ++ the lists of factors.

Implementation ==> add

C == with

```

completeEval  :      (SUP P,List OV,List R)          -> SUP R
  ++ completeEval(upoly, lvar, lval) evaluates the polynomial upoly
  ++ with each variable in lvar replaced by the corresponding value
  ++ in lval. Substitutions are done for all variables in upoly
  ++ producing a univariate polynomial over R.
degree        :      (SUP P,List OV)                  -> List NNI
  ++ degree(upoly, lvar) returns a list containing the maximum
  ++ degree for each variable in lvar.
variables      :      SUP P                            -> List OV
  ++ variables(upoly) returns the list of variables for the coefficients
  ++ of upoly.
lowerPolynomial:      SUP P                            -> SUP R
  ++ lowerPolynomial(upoly) converts upoly to be a univariate polynomial
  ++ over R. An error if the coefficients contain variables.
raisePolynomial:      SUP R                            -> SUP P
  ++ raisePolynomial(rpoly) converts rpoly from a univariate polynomial
  ++ over r to be a univariate polynomial with polynomial coefficients.
normalDeriv    :      (SUP P,Z)                        -> SUP P
  ++ normalDeriv(poly,i) computes the ith derivative of poly divided
  ++ by i!.
ran            :      Z                                -> R
  ++ ran(k) computes a random integer between -k and k as a member of R.

createZechTable: SUP -> ARR
++ createZechTable(f) generates a Zech logarithm table for the cyclic
++ group representation of a extension of the ground field by the
++ primitive polynomial {\em f(x)}, i.e. \spad{Z(i)},
++ defined by {\em x**Z(i) = 1+x**i} is stored at index i.
++ This is needed in particular
++ to perform addition of field elements in finite fields represented
++ in this way. See \spadtype{FFCGP}, \spadtype{FFCGX}.
createMultiplicationTable: SUP -> V L TERM
++ createMultiplicationTable(f) generates a multiplication
++ table for the normal basis of the field extension determined
++ by {\em f}. This is needed to perform multiplications
++ between elements represented as coordinate vectors to this basis.
++ See \spadtype{FFNBP}, \spadtype{FFNBX}.
createMultiplicationMatrix: V L TERM -> M GF
++ createMultiplicationMatrix(m) forms the multiplication table
++ {\em m} into a matrix over the ground field.
-- only useful for the user to visualise the multiplication table
-- in a nice form
sizeMultiplication: V L TERM -> NNI
++ sizeMultiplication(m) returns the number of entries
++ of the multiplication table {\em m}.
-- the time of the multiplication of field elements depends
-- on this size
createLowComplexityTable: PI -> Union(Vector List TERM,"failed")
++ createLowComplexityTable(n) tries to find
++ a low complexity normal basis of degree {\em n} over {\em GF}
++ and returns its multiplication matrix
++ Fails, if it does not find a low complexity basis
createLowComplexityNormalBasis: PI -> Union(SUP, V L TERM)
++ createLowComplexityNormalBasis(n) tries to find a
++ a low complexity normal basis of degree {\em n} over {\em GF}
++ and returns its multiplication matrix

```

```

++ If no low complexity basis is found it calls
++ \axiomFunFrom{createNormalPoly}{FiniteFieldPolynomialPackage}(n)
++ to produce a normal

-- ++ createNormalPrimitivePoly(n)$FFPOLY(GF) generates a normal and
```

```

++ primitive polynomial of degree n over the field {\em GF}.
++ Note: this function is equivalent to createPrimitiveNormalPoly(n)
createPrimitiveNormalPoly : PI -> SUP
++ createPrimitiveNormalPoly(n)$FFPOLY(GF) generates a normal and
++ primitive polynomial of degree n over the field {\em GF}.
++ polynomial of degree n over the field {\em GF}.
nextIrreduciblePoly : SUP -> Union(SUP, "failed")
++ nextIrreduciblePoly(f) yields the next monic irreducible polynomial
++ over a finite field {\em GF} of the same degree as f in the following
++ order, or "failed" if there are no greater ones.
++ Error: if f has degree 0.
++ Note: the input polynomial f is made monic.
++ Also, \spad{f < g} if
++ the number of monomials of f is less
++ than this number for g.
++ If f and g have the same number of monomials,
++ the lists of exponents are compared lexicographically.
++ If these lists are also equal, the lists of coefficients
++ are compared according to the lexicographic ordering induced by
++ the ordering of the elements of {\em GF} given by {\em lookup}.
nextPrimitivePoly : SUP -> Union(SUP, "failed")
++ nextPrimitivePoly(f) yields the next primitive polynomial over
++ a finite field {\em GF} of the same degree as f in the following
++ order, or "failed" if there are no greater ones.
++ Error: if f has degree 0.
++ Note: the input polynomial f is made monic.
++ Also, \spad{f < g} if the {\em lookup} of the constant term
++ of f is less than
++ this number for g.
++ If these values are equal, then \spad{f < g} if
++ if the number of monomials of f is less than that for g or if
++ the lists of exponents of f are lexicographically less than the
++ corresponding list for g.
++ If these lists are also equal, the lists of coefficients are
++ compared according to the lexicographic ordering induced by
++ the ordering of the elements of {\em GF} given by {\em lookup}.
nextNormalPoly : SUP -> Union(SUP, "failed")
++ nextNormalPoly(f) yields the next normal polynomial over
++ a finite field {\em GF} of the same degree as f in the following
++ order, or "failed" if there are no greater ones.
++ Error: if f has degree 0.
++ Note: the input polynomial f is made monic.
++ Also, \spad{f < g} if the {\em lookup} of the coefficient
++ of the term of degree
++ {\em n-1} of f is less than that for g.
++ In case these numbers are equal, \spad{f < g} if

```

```

++ if the number of monomials of f is less than that for g or if
++ the list of exponents of f are lexicographically less than the
++ corresponding list for g.
++ If these lists are also equal, the lists of coefficients are
++ compared according to the lexicographic ordering induced by
++ the ordering of the elements of {\em GF} given by {\em lookup}.
nextNormalPrimitivePoly : SUP -> Union(SUP, "failed")
++ nextNormalPrimitivePoly(f) yields the next normal primitive polynomial
++ over a finite field {\em GF} of the same degree as f in the following
++ order, or "failed" if there are no greater ones.
++ Error: if f has degree 0.
++ Note: the input polynomial f is made monic.
++ Also, \spad{f < g} if the {\em lookup} of the constant
++ term of f is less than
++ this number for g or if
++ {\em lookup} of the coefficient of the term of degree {\em n-1}
++ of f is less than this number for g.
++ Otherwise, \spad{f < g}
++ if the number of monomials of f is less than
++ that for g or if the lists of exponents for f are
++ lexicographically less than those for g.
++ If these lists are also equal, the lists of coefficients are
++ compared according to the lexicographic ordering induced by
++ the ordering of the elements of {\em GF} given by {\em lookup}.
++ This operation is equivalent to nextPrimitiveNormalPoly(f).
nextPrimitiveNormalPoly : SUP -> Union(SUP, "failed")
++ nextPrimitiveNormalPoly(f) yields the next primitive normal polynomial
++ over a finite field {\em GF} of the same degree as f in the following
++ order, or "failed" if there are no greater ones.
++ Error: if f has degree 0.
++ Note: the input polynomial f is made monic.
++ Also, \spad{f < g} if the {\em lookup} of the
++ constant term of f is less than
++ this number for g or, in case these numbers are equal, if the
++ {\em lookup} of the coefficient of the term of degree {\em n-1}
++ of f is less than this number for g.
++ If these numbers are equal, \spad{f < g}
++ if the number of monomials of f is less than
++ that for g, or if the lists of exponents for f are lexicographically
++ less than those for g.
++ If these lists are also equal, the lists of coefficients are
++ compared according to the lexicographic ordering induced by
++ the ordering of the elements of {\em GF} given by {\em lookup}.
++ This operation is equivalent to nextNormalPrimitivePoly(f).
-- random : () -> SUP
-- ++ random()$FFPOLY(GF) generates a random monic polynomial

```

```

--      ++ of random degree over the field {\em GF}
random : PI -> SUP
    ++ random(n)$FFPOLY(GF) generates a random monic polynomial
    ++ of degree n over the finite field {\em GF}.
random : (PI, PI) -> SUP
    ++ random(m,n)$FFPOLY(GF) generates a random monic polynomial
    ++ of degree d over the finite field {\em GF}, d between m and n.
leastAffineMultiple: SUP -> SUP
    ++ leastAffineMultiple(f) computes the least affine polynomial which
    ++ is divisible by the polynomial f over the finite field {\em GF},
    ++ i.e. a polynomial whose exponents are 0 or a power of q, the
    ++ size of {\em GF}.
reducedQPowers: SUP -> PrimitiveArray SUP
    ++ reducedQPowers(f)
    ++ generates \spad{[x,x**q,x**(q**2),...,x**(q**(n-1))]}
    ++ reduced modulo f where \spad{q = size()$GF} and \spad{n = degree f}.
--
-- we intend to implement also the functions

--% FiniteLinearAggregateFunctions2
```

```
++ Author: ???
++ Date Created: ???
++ Date Last Updated: ???
++ Description:
++ FiniteLinearAggregateFunctions2 provides functions involving two
++ FiniteLinearAggregates where the underlying domains might be
++ different. An example of this might be creating a list of rational
++ numbers by mapping a function across a list of integers where the
++ function divides each integer by 1000.
```

FiniteLinearAggregateFunctions2(S, A, R, B):

Exports == Implementation where

S, R: Type

A : FiniteLinearAggregate S

B : FiniteLinearAggregate R

Exports ==> with

map : (S -> R, A) -> B

```
++ map(f,a) applies function f to each member of aggregate
++ \spad{a} resulting in a new aggregate over a
++ possibly different underlying domain.
```

reduce : ((S, R) -> R, A, R) -> R

```
++ reduce(f,a,r) applies function f to each
```

```

++ successive element of the
++ aggregate \spad{a} and an accumulant initialized to r.
++ For example,
++ \spad{reduce(_+$Integer,[1,2,3],0)}
++ does \spad{3+(2+(1+0))}. Note: third argument r
++ may be regarded as the
++ identity element for the function f.
scan  : ((S, R) -> R, A, R) -> B
++ scan(f,a,r) successively applies
++ \spad{reduce(f,x,r)} to more and more leading sub-aggregates
++ x of aggregate \spad{a}.
++ More precisely, if \spad{a} is \spad{[a1,a2,...]}, then
++ \spad{scan(f,a,r)} returns
++ \spad{[reduce(f,[a1],r),reduce(f,[a1,a2],r),...]}.

```

```
++ Author: Robert S. Sutor
```

```
++ Date Created: 15 May 1990
```

```
++ Date Last Updated: 14 Oct 1993
```

```
++ Description:
```

```
++ FiniteSetAggregateFunctions2 provides functions involving two
```

```
++ finite set aggregates where the underlying domains might be
```

```
++ different. An example of this is to create a set of rational
```

```
++ numbers by mapping a function across a set of integers, where the
```

```
++ function divides each integer by 1000.
```

```
FiniteSetAggregateFunctions2(S, A, R, B): Exports == Implementation where
```

```
S, R: SetCategory
```

```
A : FiniteSetAggregate S
```

```
B : FiniteSetAggregate R
```

```
Exports ==> with
```

```
map : (S -> R, A) -> B
```

```
++ map(f,a) applies function f to each member of
```

```
++ aggregate \spad{a}, creating a new aggregate with
```

```
++ a possibly different underlying domain.
```

```
reduce : ((S, R) -> R, A, R) -> R
```

```
++ reduce(f,a,r) applies function f to each
```

```

++ successive element of the aggregate \spad{a} and an
++ accumulant initialised to r.
++ For example,
++ \spad{reduce(_+$Integer,[1,2,3],0)}
++ does a \spad{3+(2+(1+0))}.
++ Note: third argument r may be regarded
++ as an identity element for the function.
scan  : ((S, R) -> R, A, R) -> B
++ scan(f,a,r) successively applies \spad{reduce(f,x,r)}
++ to more and more leading sub-aggregates x of
++ aggregate \spad{a}.
++ More precisely, if \spad{a} is \spad{[a1,a2,...]}, then
++ \spad{scan(f,a,r)} returns
++ \spad {[reduce(f,[a1],r),reduce(f,[a1,a2],r),...]}
Implementation ==> add

++ Keywords:

++ References:

++ Description:

++ \spadtype{FortranCodePackage1} provides some utilities for
++ producing useful objects in FortranCode domain.

++ The Package may be used with the FortranCode domain and its
++ \spad{printCode} or possibly via an outputAsFortran.

++ (The package provides items of use in connection with ASPs
++ in the AXIOM-NAG link and, where appropriate, naming accords
++ with that in IRENA.)

++ The easy-to-use functions use Fortran loop variables I1, I2,
++ and it is users' responsibility to check that this is sensible.

++ The advanced functions use SegmentBinding to allow users control
++ over Fortran loop variable names.

-- Later might add functions to build

-- diagonalMatrix from List, i.e. the FC version of the corresponding

-- AXIOM function from MatrixCategory;

-- bandedMatrix, i.e. the full-matrix-FC version of the corresponding

-- AXIOM function in BandedMatrix Domain

```

fffg: (List D, cFunction, List NonNegativeInteger) -> Matrix SUP D
++ \spad{fffg} is the general algorithm as proposed by Beckermann and
++ Labahn.
++
  
```

```

++ The first argument is the list of  $c_{\{i,i\}}$ . These are the only values
++ of  $C$  explicitly needed in \spad{fffg}.
++
++ The second argument  $c$ , computes  $c_k(M)$ , i.e.,  $c_k(\cdot)$  is the dual basis
++ of the vector space  $V$ , but also knows about the special multiplication
++ rule as descibed in Equation (2). Note that the information about  $f$ 
++ is therefore encoded in  $c$ .
++
++ The third argument is the vector of degree bounds  $n$ , as introduced in
++ Definition 2.1. In particular, the sum of the entries is the order of
++ the Mahler system computed.

interpolate: (List D, List D, NonNegativeInteger) -> Fraction SUP D
++ \spad{interpolate(xlist, ylist, deg)} returns the rational function with
++ numerator degree at most \spad{deg} and denominator degree at most
++ \spad{#xlist-deg-1} that interpolates the given points using
++ fraction free arithmetic. Note that rational interpolation does not
++ guarantee that all given points are interpolated correctly:
++ unattainable points may make this impossible.

```

The following function could be moved to `{\tt{}FFFGF}`, parallel to `{\tt{}generalInterpolation}`. However, the reason for moving `{\tt{}generalInterpolation}` for fractions to a separate package was the need of a generic signature, hence the extra argument `{\tt{}VF}` to `{\tt{}FFFGF}`. In the special case of rational interpolation, this extra argument is not necessary, since we are always returning a fraction of `{\tt{}SUP}`s, and ignore `{\tt{}V}`. In fact, `{\tt{}V}` is not needed for `{\tt{}fffg}` itself, only if we want to specify a `{\tt{}CoeffAction}`.

Thus, maybe it would be better to move `{\tt{}fffg}` to a separate package?

```
(package FFFG FractionFreeFastGaussian)+≡
interpolate: (List Fraction D, List Fraction D, NonNegativeInteger)
-> Fraction SUP D
++ \spad{interpolate(xlist, ylist, deg)} returns the rational function with
++ numerator degree \spad{deg} that interpolates the given points using
++ fraction free arithmetic.

generalInterpolation: (List D, CoeffAction,
    Vector V, List NonNegativeInteger) -> Matrix SUP D
++ \spad{generalInterpolation(C, CA, f, eta)} performs Hermite-Pade
++ approximation using the given action CA of polynomials on the elements
++ of f. The result is guaranteed to be correct up to order
++ |eta|-1. Given that eta is a "normal" point, the degrees on the
++ diagonal are given by eta. The degrees of column i are in this case
++ eta + e.i - [1,1,...,1], where the degree of zero is -1.
++
++ The first argument C is the list of coefficients c_{k,k} in the
++ expansion <x^k> z g(x) = sum_{i=0}^k c_{k,i} <x^i> g(x).
++
++ The second argument, CA(k, 1, f), should return the coefficient of x^k
++ in z^1 f(x).

generalInterpolation: (List D, CoeffAction,
    Vector V, NonNegativeInteger, NonNegativeInteger)
-> Stream Matrix SUP D
++ \spad{generalInterpolation(C, CA, f, sumEta, maxEta)} applies
++ \spad{generalInterpolation(C, CA, f, eta)} for all possible \spad{eta}
++ with maximal entry \spad{maxEta} and sum of entries at most
++ \spad{sumEta}.
++
++ The first argument C is the list of coefficients c_{k,k} in the
++ expansion <x^k> z g(x) = sum_{i=0}^k c_{k,i} <x^i> g(x).
++
++ The second argument, CA(k, 1, f), should return the coefficient of x^k
++ in z^1 f(x).
```

```

generalCoefficient: (CoeffAction, Vector V,
                    NonNegativeInteger, Vector SUP D) -> D
++ \spad{generalCoefficient(action, f, k, p)} gives the coefficient of
++  $x^k$  in  $p(z) \cdot f(x)$ , where the action of  $z^1$  on a polynomial in  $x$  is
++ given by action, i.e.,  $\text{action}(k, 1, f)$  should return the coefficient
++ of  $x^k$  in  $z^1 f(x)$ .

ShiftAction: (NonNegativeInteger, NonNegativeInteger, V) -> D
++ \spad{ShiftAction(k, 1, g)} gives the coefficient of  $x^k$  in  $z^1 g(x)$ ,
++ where  $\text{spad}\{z*(a+b*x+c*x^2+d*x^3+...)\} = (b*x+2*c*x^2+3*d*x^3+...)$ . In
++ terms of sequences,  $z*u(n)=n*u(n)$ .

ShiftC: NonNegativeInteger -> List D
++ \spad{ShiftC} gives the coefficients  $c_{\{k,k\}}$  in the expansion  $\langle x^k \rangle z$ 
++  $g(x) = \sum_{i=0}^k c_{\{k,i\}} \langle x^i \rangle g(x)$ , where  $z$  acts on  $g(x)$  by
++ shifting. In fact, the result is  $[0,1,2,...]$ 

DiffAction: (NonNegativeInteger, NonNegativeInteger, V) -> D
++ \spad{DiffAction(k, 1, g)} gives the coefficient of  $x^k$  in  $z^1 g(x)$ ,
++ where  $z*(a+b*x+c*x^2+d*x^3+...) = (a*x+b*x^2+c*x^3+...)$ , i.e.,
++ multiplication with  $x$ .

DiffC: NonNegativeInteger -> List D
++ \spad{DiffC} gives the coefficients  $c_{\{k,k\}}$  in the expansion  $\langle x^k \rangle z$ 
++  $g(x) = \sum_{i=0}^k c_{\{k,i\}} \langle x^i \rangle g(x)$ , where  $z$  acts on  $g(x)$  by
++ shifting. In fact, the result is  $[0,0,0,...]$ 

qShiftAction: (D, NonNegativeInteger, NonNegativeInteger, V) -> D
++ \spad{qShiftAction(q, k, 1, g)} gives the coefficient of  $x^k$  in  $z^1$ 
++  $g(x)$ , where  $z*(a+b*x+c*x^2+d*x^3+...) =$ 
++  $(a+q*b*x+q^2*c*x^2+q^3*d*x^3+...)$ . In terms of sequences,
++  $z*u(n)=q^n*u(n)$ .

qShiftC: (D, NonNegativeInteger) -> List D
++ \spad{qShiftC} gives the coefficients  $c_{\{k,k\}}$  in the expansion  $\langle x^k \rangle z$ 
++  $g(x) = \sum_{i=0}^k c_{\{k,i\}} \langle x^i \rangle g(x)$ , where  $z$  acts on  $g(x)$  by
++ shifting. In fact, the result is  $[1,q,q^2,...]$

```

The following function returns the lexicographically next vector with non-negative components smaller than p with the same sum as v .

```

(package FFFG FractionFreeFastGaussian)+≡
nextVector!(p: NonNegativeInteger, v: List NonNegativeInteger)
: Union("failed", List NonNegativeInteger) ==

n := #v
pos := position(x +-> x < p, v)
zero? pos => return "failed"
if pos = 1 then
  sum: Integer := v.1
  for i in 2..n repeat
    if v.i < p and sum > 0 then
      v.i := v.i + 1
      sum := sum - 1
      for j in 1..i-1 repeat
        if sum > p then
          v.j := p
          sum := sum - p
        else
          v.j := sum::NonNegativeInteger
          sum := 0
      return v
    else sum := sum + v.i
  return "failed"
else
  v.pos := v.pos + 1
  v.(pos-1) := (v.(pos-1) - 1)::NonNegativeInteger

v

```

The following function returns the stream of all possible degree vectors, beginning with v , where the degree vectors are sorted in reverse lexicographic order. Furthermore, the entries are all less or equal to p and their sum equals the sum of the entries of v . We assume that the entries of v are also all less or equal to p .

```

(package FFFG FractionFreeFastGaussian)+≡
vectorStream(p: NonNegativeInteger, v: List NonNegativeInteger)
: Stream List NonNegativeInteger == delay
next := nextVector!(p, copy v)
(next case "failed") => empty()$Stream(List NonNegativeInteger)
cons(next, vectorStream(p, next))

```

`vectorStream2` skips every second entry of `vectorStream`.

```

⟨package FFFG FractionFreeFastGaussian⟩+≡
  vectorStream2(p: NonNegativeInteger, v: List NonNegativeInteger)
    : Stream List NonNegativeInteger == delay
    next := nextVector!(p, copy v)
    (next case "failed") => empty()$Stream(List NonNegativeInteger)
    next2 := nextVector!(p, copy next)
    (next2 case "failed") => cons(next, empty())
    cons(next2, vectorStream2(p, next2))

```

This version of `generalInterpolation` returns a stream of solutions, one for each possible degree vector. Thus, it only needs to apply the previously defined `generalInterpolation` to each degree vector. These are generated by `vectorStream` and `vectorStream2` respectively.

If `f` consists of two elements only, we can skip every second degree vector: note that `fffg`, and thus also `generalInterpolation`, returns a matrix with `#f` columns, each corresponding to a solution of the interpolation problem. More precisely, the i^{th} column is a solution with degrees $\mathbf{eta} - (1, 1, \dots, 1) + e_i$. Thus, in the case of 2×2 matrices, `vectorStream` would produce solutions corresponding to $(d, 0), (d-1, 1); (d-1, 1), (d-2, 2); (d-2, 2), (d-3, 3) \dots$, i.e., every second matrix is redundant.

Although some redundancy exists also for higher dimensional `f`, the scheme becomes much more complicated, thus we did not implement it.

```

⟨package FFFG FractionFreeFastGaussian⟩+≡
  generalInterpolation(C: List D, coeffAction: CoeffAction,
    f: Vector V,
    sumEta: NonNegativeInteger,
    maxEta: NonNegativeInteger)
    : Stream Matrix SUP D ==

    ⟨generate an initial degree vector⟩

    if #f = 2 then
      map(x +-> generalInterpolation(C, coeffAction, f, x),
        cons(eta, vectorStream2(maxEta, eta)))
      $StreamFunctions2(List NonNegativeInteger,
        Matrix SUP D)
    else
      map(x +-> generalInterpolation(C, coeffAction, f, x),
        cons(eta, vectorStream(maxEta, eta)))
      $StreamFunctions2(List NonNegativeInteger,
        Matrix SUP D)

```

We need to generate an initial degree vector, being the minimal element in reverse lexicographic order, i.e., $m, m, \dots, m, k, 0, 0, \dots$, where m is `maxEta` and k is the remainder of `sumEta` divided by `maxEta`. This is done by the following code:

```

<generate an initial degree vector>≡
  sum: Integer := sumEta
  entry: Integer
  eta: List NonNegativeInteger
  := [(if sum < maxEta _
      then (entry := sum; sum := 0) _
      else (entry := maxEta; sum := sum - maxEta); _
      entry::NonNegativeInteger) for i in 1..#f]

```

We want to generate all vectors with sum of entries being at most `sumEta`. Therefore the following is incorrect.

```

<BUG generate an initial degree vector>≡
  -- (sum > 0) => empty()$Stream(Matrix SUP D)

```

(package FFFG FractionFreeFastGaussian)+≡

 -- rational interpolation

```

interpolate(x: List Fraction D, y: List Fraction D, d: NonNegativeInteger)
  : Fraction SUP D ==
  gx := splitDenominator(x)$InnerCommonDenominator(D, Fraction D, _
                                                    List D, _
                                                    List Fraction D)
  gy := splitDenominator(y)$InnerCommonDenominator(D, Fraction D, _
                                                    List D, _
                                                    List Fraction D)

  r := interpolate(gx.num, gy.num, d)
  elt(numer r, monomial(gx.den,1))/(gy.den*elt(denom r, monomial(gx.den,1)))

interpolate(x: List D, y: List D, d: NonNegativeInteger): Fraction SUP D ==
-- berechne Interpolante mit Graden d und N-d-1
  if (N := #x) ~= #y then
    error "interpolate: number of points and values must match"
  if N <= d then
    error "interpolate: numerator degree must be smaller than number of data points"
  c: cFunction := (s,u) +-> y.s * elt(u.2, x.s) - elt(u.1, x.s)
  eta: List NonNegativeInteger := [d, (N-d)::NonNegativeInteger]
  M := fffg(x, c, eta)

  if zero?(M.(2,1)) then M.(1,2)/M.(2,2)
    else M.(1,1)/M.(2,1)

```

Because of Lemma 5.3, $M.1.(2,1)$ and $M.1.(2,2)$ cannot both vanish, since $\mathbf{eta_sigma}$ is always σ -normal by Theorem 7.2 and therefore also para-normal, see Definition 4.2.

Because of Lemma 5.1 we have that $M.1.(*,2)$ is a solution of the interpolation problem, if $M.1.(2,1)$ vanishes.

(package FFFG FractionFreeFastGaussian)+≡

 -- fffg

recurrence computes the new matrix M , according to the following formulas (cf. Table 2 in Beckermann and Labahn):

$$\begin{aligned}
 & \text{Increase order} \\
 & \text{for } \ell = 1 \dots m, \ell \neq \pi \\
 & \mathbf{M}_{\sigma+1}^{(\cdot, \ell)} := \left(\mathbf{M}_{\sigma}^{(\cdot, \ell)} r^{(\pi)} - \mathbf{M}_{\sigma}^{(\cdot, \pi)} r^{(\ell)} \right) / d_{\sigma} \\
 & \text{Increase order in column } \pi \\
 & \mathbf{M}_{\sigma+1}^{(\cdot, \pi)} := (z - c_{\sigma, \sigma}) \mathbf{M}_{\sigma}^{(\cdot, \pi)} \\
 & \text{Adjust degree constraints:} \\
 & \mathbf{M}_{\sigma+1}^{(\cdot, \pi)} := \left(\mathbf{M}_{\sigma+1}^{(\cdot, \pi)} r^{(\pi)} - \sum_{\ell \neq \pi} \mathbf{M}_{\sigma+1}^{(\cdot, \ell)} p^{(\ell)} \right) / d_{\sigma}
 \end{aligned}$$

Since we do not need the matrix \mathbf{M}_{σ} anymore, we drop the index and update the matrix destructively. In the following, we write \mathbf{Ck} for $c_{\sigma, \sigma}$.

```

7.54.1 differentiation of special functions

In the following we define the symbolic derivatives of the special functions we provide. The formulas we use for the Bessel functions can be found in Milton Abramowitz and Irene A. Stegun, eds. (1965). *Handbook of Mathematical Functions with Formulas, Graphs, and Mathematical Tables*. New York: Dover. ISBN 0-486-61272-4, Equations 9.1.27 and 9.6.26. Up to `patch--50` the formula for K missed the minus sign. (Issue #355)

We do not attempt to provide formulas for the derivative with respect to the first argument currently. Instead, we leave such derivatives unevaluated.

```

⟨package FSPECF FunctionalSpecialFunction⟩+≡
import Fraction Integer
ahalf: F := recip(2::F)::F
athird: F := recip(3::F)::F
twothirds: F := 2*recip(3::F)::F

```

We need to get hold of the differentiation operator as modified by `FunctionSpace`. Otherwise, for example, display will be ugly. We accomplish that by differentiating an operator, which will certainly result in a single kernel only.

```
<package FSPECF FunctionalSpecialFunction>+≡
  dummyArg: SE := new()$SE
  opdiff := operator first kernels D((operator(new()$SE)$BasicOperator)
                                     (dummyArg::F), dummyArg)
```

The differentiation operator `opdiff` takes three arguments corresponding to

$$F_{,i}(a_1, a_2, \dots, a_n) :$$

1. $F(a_1, \dots, dm, \dots, a_n)$, where the i^{th} argument is a dummy variable,
2. dm , the dummy variable, and
3. a_i , the point at which the differential is evaluated.

In the following, it seems to be safe to use the same dummy variable throughout. At least, this is done also in `FunctionSpace`, and did not cause problems.

The operation `symbolicGrad` returns the first component of the gradient of `op l`.

```
<package FSPECF FunctionalSpecialFunction>+≡
  dm := new()$SE :: F

  iBesselJ(l: List F, t: SE): F ==
    n := first l; x := second l
    differentiate(n, t)*kernel(opdiff, [opBesselJ [dm, x], dm, n])
    + differentiate(x, t) * ahalf * (besselJ (n-1,x) - besselJ (n+1,x))

  iBesselY(l: List F, t: SE): F ==
    n := first l; x := second l
    differentiate(n, t)*kernel(opdiff, [opBesselY [dm, x], dm, n])
    + differentiate(x, t) * ahalf * (besselY (n-1,x) - besselY (n+1,x))

  iBesselI(l: List F, t: SE): F ==
    n := first l; x := second l
    differentiate(n, t)*kernel(opdiff, [opBesselI [dm, x], dm, n])
    + differentiate(x, t)* ahalf * (besselI (n-1,x) + besselI (n+1,x))

  iBesselK(l: List F, t: SE): F ==
    n := first l; x := second l
    differentiate(n, t)*kernel(opdiff, [opBesselK [dm, x], dm, n])
    - differentiate(x, t)* ahalf * (besselK (n-1,x) + besselK (n+1,x))
```

For the moment we throw an error if we try to differentiate `polygamma` with respect to the first argument.

```

(package FSPECF FunctionalSpecialFunction)+≡
  ipolygamma(l: List F, x: SE): F ==
    member?(x, variables first l) =>
      error "cannot differentiate polygamma with respect to the first argum
    n := first l; y := second l
    differentiate(y, x)*polygamma(n+1, y)
  iBetaGrad1(l: List F): F ==
    x := first l; y := second l
    Beta(x,y)*(digamma x - digamma(x+y))
  iBetaGrad2(l: List F): F ==
    x := first l; y := second l
    Beta(x,y)*(digamma y - digamma(x+y))

  if F has ElementaryFunctionCategory then
    iGamma2(l: List F, t: SE): F ==
      a := first l; x := second l
      differentiate(a, t)*kernel(opdiff, [opGamma2 [dm, x], dm, a])
      - differentiate(x, t)* x ** (a - 1) * exp(-x)
    setProperty(opGamma2, SPECIALDIFF, iGamma2@((List F, SE)->F)
      pretend None)

```

Finally, we tell Axiom to use these functions for differentiation. Note that up to `patch--50`, the properties for the Bessel functions were set using `derivative(oppolygamma, [lzero, ipolygammaGrad])`, where `lzero` returned zero always. Trying to replace `lzero` by a function that returns the first component of the gradient failed, it resulted in an infinite loop for `integrate(D(besselJ(a,x),a),a)`.

```

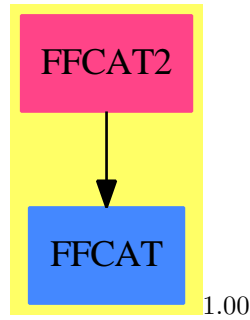

(package FSPECF FunctionalSpecialFunction)+≡
  derivative(opabs,      (x:F):F --> abs(x) * inv(x))
  derivative(opGamma,    (x:F):F --> digamma x * Gamma x)
  derivative(opBeta,     [iBetaGrad1, iBetaGrad2])
  derivative(opdigamma,  (x:F):F --> polygamma(1, x))
  setProperty(oppolygamma, SPECIALDIFF, ipolygamma@((List F, SE)->F)
    pretend None)
  setProperty(opBesselJ, SPECIALDIFF, iBesselJ@((List F, SE)->F)
    pretend None)
  setProperty(opBesselY, SPECIALDIFF, iBesselY@((List F, SE)->F)
    pretend None)
  setProperty(opBesselI, SPECIALDIFF, iBesselI@((List F, SE)->F)
    pretend None)
  setProperty(opBesselK, SPECIALDIFF, iBesselK@((List F, SE)->F)
    pretend None)

++ Computation of primitive elements.

++ Author: Manuel Bronstein

++ Date Created: 6 Jun 1990

++ Date Last Updated: 25 April 1991

++ Description:

++ FunctionsSpacePrimitiveElement provides functions to compute

++ primitive elements in functions spaces;

++ Keywords: algebraic, extension, primitive.

FunctionSpacePrimitiveElement(R, F): Exports == Implementation where

R: Join(IntegralDomain, OrderedSet, CharacteristicZero)

F: FunctionSpace R

SY ==> Symbol

P ==> Polynomial F

K ==> Kernel F

UP ==> SparseUnivariatePolynomial F

REC ==> Record(primelt:F, poly:List UP, prim:UP)

Exports ==> with

primitiveElement: List F -> Record(primelt:F, poly:List UP, prim:UP)

++ primitiveElement([a1,...,an]) returns \spad{[a, [q1,...,qn], q]}

++ such that then \spad{k(a1,...,an) = k(a)},

++ \spad{ai = qi(a)}, and \spad{q(a) = 0}.

++ This operation uses the technique of

++ \spadglossSee{groebner bases}{Groebner basis}.

```

if F has AlgebraicallyClosedField then
  primitiveElement: (F,F)->Record(primelt:F,pol1:UP,pol2:UP,prim:UP)
  ++ primitiveElement(a1, a2) returns \spad{[a, q1, q2, q]}
  ++ such that \spad{k(a1, a2) = k(a)},
  ++ \spad{ai = qi(a)}, and \spad{q(a) = 0}.
  ++ The minimal polynomial for a2 may involve a1, but the
  ++ minimal polynomial for a1 may not involve a2;
  ++ This operations uses \spadfun{resultant}.

```

++ Description:

++ This package converts expressions in some function space to power series in a variable x with coefficients in that function space. The function `\spadfun{exprToUPS}` converts expressions to power series whose coefficients do not contain the variable x . The function `\spadfun{exprToGenUPS}` converts functional expressions to power series whose coefficients may involve functions of `\spad{log(x)}`.

  exprToUPS : (FE,B,S) -> Result
    ++ exprToUPS(fcn,posCheck?,atanFlag) converts the expression
    ++ \spad{fcn} to a power series.  If \spad{posCheck?} is true,
    ++ log's of negative numbers are not allowed nor are nth roots of
    ++ negative numbers with n even.  If \spad{posCheck?} is false,
    ++ these are allowed.  \spad{atanFlag} determines how the case
    ++ \spad{atan(f(x))}, where \spad{f(x)} has a pole, will be treated.
    ++ The possible values of \spad{atanFlag} are \spad{"complex"},
    ++ \spad{"real: two sides"}, \spad{"real: left side"},
    ++ \spad{"real: right side"}, and \spad{"just do it"}.
    ++ If \spad{atanFlag} is \spad{"complex"}, then no series expansion
    ++ will be computed because, viewed as a function of a complex
    ++ variable, \spad{atan(f(x))} has an essential singularity.
    ++ Otherwise, the sign of the leading coefficient of the series
    ++ expansion of \spad{f(x)} determines the constant coefficient

```

```

++ in the series expansion of \spad{atan(f(x))}. If this sign cannot
++ be determined, a series expansion is computed only when
++ \spad{atanFlag} is \spad{"just do it"}. When the leading term
++ in the series expansion of \spad{f(x)} is of odd degree (or is a
++ rational degree with odd numerator), then the constant coefficient
++ in the series expansion of \spad{atan(f(x))} for values to the
++ left differs from that for values to the right. If \spad{atanFlag}
++ is \spad{"real: two sides"}, no series expansion will be computed.
++ If \spad{atanFlag} is \spad{"real: left side"} the constant
++ coefficient for values to the left will be used and if \spad{atanFlag}
++ \spad{"real: right side"} the constant coefficient for values to the
++ right will be used.
++ If there is a problem in converting the function to a power series,
++ a record containing the name of the function that caused the problem
++ and a brief description of the problem is returned.
++ When expanding the expression into a series it is assumed that
++ the series is centered at 0. For a series centered at a, the
++ user should perform the substitution \spad{x -> x + a} before calling
++ this function.

```

```

exprToGenUPS : (FE,B,S) -> Result

```

```

++ exprToGenUPS(fcn,posCheck?,atanFlag) converts the expression
++ \spad{fcn} to a generalized power series. If \spad{posCheck?}
++ is true, log's of negative numbers are not allowed nor are nth roots
++ of negative numbers with n even. If \spad{posCheck?} is false,
++ these are allowed. \spad{atanFlag} determines how the case
++ \spad{atan(f(x))}, where \spad{f(x)} has a pole, will be treated.
++ The possible values of \spad{atanFlag} are \spad{"complex"},
++ \spad{"real: two sides"}, \spad{"real: left side"},
++ \spad{"real: right side"}, and \spad{"just do it"}.
++ If \spad{atanFlag} is \spad{"complex"}, then no series expansion
++ will be computed because, viewed as a function of a complex
++ variable, \spad{atan(f(x))} has an essential singularity.
++ Otherwise, the sign of the leading coefficient of the series
++ expansion of \spad{f(x)} determines the constant coefficient
++ in the series expansion of \spad{atan(f(x))}. If this sign cannot
++ be determined, a series expansion is computed only when
++ \spad{atanFlag} is \spad{"just do it"}. When the leading term
++ in the series expansion of \spad{f(x)} is of odd degree (or is a
++ rational degree with odd numerator), then the constant coefficient
++ in the series expansion of \spad{atan(f(x))} for values to the
++ left differs from that for values to the right. If \spad{atanFlag}
++ is \spad{"real: two sides"}, no series expansion will be computed.
++ If \spad{atanFlag} is \spad{"real: left side"} the constant
++ coefficient for values to the left will be used and if \spad{atanFlag}
++ \spad{"real: right side"} the constant coefficient for values to the

```

```

++ right will be used.
++ If there is a problem in converting the function to a power
++ series, we return a record containing the name of the function
++ that caused the problem and a brief description of the problem.
++ When expanding the expression into a series it is assumed that
++ the series is centered at 0. For a series centered at a, the
++ user should perform the substitution \spad{x -> x + a} before calling
++ this function.
localAbs: FE -> FE
++ localAbs(fcn) = \spad{abs(fcn)} or \spad{sqrt(fcn**2)} depending
++ on whether or not FE has a function \spad{abs}. This should be
++ a local function, but the compiler won't allow it.

```

  makeFR: FinalFact -> Factored UP
    ++ makeFR(flist) turns the final factorization of henselFact into a
    ++ \spadtype{Factored} object.
  degreePartition: DDLList -> Multiset N
    ++ degreePartition(ddfactorization) returns the degree partition of
    ++ the polynomial f modulo p where ddfactorization is the distinct
    ++ degree factorization of f computed by
    ++ \spadfunFrom{ddFact}{ModularDistinctDegreeFactorizer}
    ++ for some prime p.
  musserTrials: () -> P
    ++ musserTrials() returns the number of primes that are tried in
    ++ \spadfun{modularFactor}.
  musserTrials: P -> P
    ++ musserTrials(n) sets to n the number of primes to be tried in
    ++ \spadfun{modularFactor} and returns the previous value.
  stopMusserTrials: () -> P
    ++ stopMusserTrials() returns the bound on the number of factors for
    ++ which \spadfun{modularFactor} stops to look for an other prime. You
    ++ will have to remember that the step of recombining the extraneous
    ++ factors may take up to \spad{2**stopMusserTrials()} trials.
  stopMusserTrials: P -> P
    ++ stopMusserTrials(n) sets to n the bound on the number of factors for
    ++ which \spadfun{modularFactor} stops to look for an other prime. You
    ++ will have to remember that the step of recombining the extraneous
    ++ factors may take up to \spad{2**n} trials. Returns the previous
    ++ value.
  numberOfFactors: DDLList -> N
    ++ numberOfFactors(ddfactorization) returns the number of factors of

```

```

++ the polynomial f modulo p where ddfactorization is the distinct
++ degree factorization of f computed by
++ \spadfunFrom{ddFact}{ModularDistinctDegreeFactorizer}
++ for some prime p.
modularFactor: UP -> MFact
++ modularFactor(f) chooses a "good" prime and returns the factorization
++ of f modulo this prime in a form that may be used by
++ \spadfunFrom{completeHensel}{GeneralHenselPackage}. If prime is zero
++ it means that f has been proved to be irreducible over the integers
++ or that f is a unit (i.e. 1 or -1).
++ f shall be primitive (i.e. content(p)=1) and square free (i.e.
++ without repeated factors).
useSingleFactorBound?: () -> Boolean
++ useSingleFactorBound?() returns \spad{true} if algorithm with single
++ factor bound is used for factorization, \spad{false} for algorithm
++ with overall bound.
useSingleFactorBound: Boolean -> Boolean
++ useSingleFactorBound(b) chooses the algorithm to be used by the
++ factorizers: \spad{true} for algorithm with single
++ factor bound, \spad{false} for algorithm with overall bound.
++ Returns the previous value.
useEisensteinCriterion?: () -> Boolean
++ useEisensteinCriterion?() returns \spad{true} if factorizers
++ check Eisenstein's criterion before factoring.
useEisensteinCriterion: Boolean -> Boolean
++ useEisensteinCriterion(b) chooses whether factorizers check
++ Eisenstein's criterion before factoring: \spad{true} for
++ using it, \spad{false} else. Returns the previous value.
eisensteinIrreducible?: UP -> Boolean
++ eisensteinIrreducible?(p) returns \spad{true} if p can be
++ shown to be irreducible by Eisenstein's criterion,
++ \spad{false} is inconclusive.
tryFunctionalDecomposition?: () -> Boolean
++ tryFunctionalDecomposition?() returns \spad{true} if
++ factorizers try functional decomposition of polynomials before
++ factoring them.
tryFunctionalDecomposition: Boolean -> Boolean
++ tryFunctionalDecomposition(b) chooses whether factorizers have
++ to look for functional decomposition of polynomials
++ (\spad{true}) or not (\spad{false}). Returns the previous value.
factor: UP -> Factored UP
++ factor(p) returns the factorization of p over the integers.
factor: (UP,N) -> Factored UP
++ factor(p,r) factorizes the polynomial p using the single factor bound
++ algorithm and knowing that p has at least r factors.
factor: (UP,List N) -> Factored UP

```

```

    ++ factor(p,listOfDegrees) factorizes the polynomial p using the single
    ++ factor bound algorithm and knowing that p has for possible
    ++ splitting of its degree listOfDegrees.
factor: (UP,List N,N) -> Factored UP
    ++ factor(p,listOfDegrees,r) factorizes the polynomial p using the single
    ++ factor bound algorithm, knowing that p has for possible
    ++ splitting of its degree listOfDegrees and that p has at least r
    ++ factors.
factor: (UP,N,N) -> Factored UP
    ++ factor(p,d,r) factorizes the polynomial p using the single
    ++ factor bound algorithm, knowing that d divides the degree of all
    ++ factors of p and that p has at least r factors.
factorSquareFree: UP -> Factored UP
    ++ factorSquareFree(p) returns the factorization of p which is supposed
    ++ not having any repeated factor (this is not checked).
factorSquareFree: (UP,N) -> Factored UP
    ++ factorSquareFree(p,r) factorizes the polynomial p using the single
    ++ factor bound algorithm and knowing that p has at least r factors.
    ++ f is supposed not having any repeated factor (this is not checked).
factorSquareFree: (UP,List N) -> Factored UP
    ++ factorSquareFree(p,listOfDegrees) factorizes the polynomial p using
    ++ the single factor bound algorithm and knowing that p has for possible
    ++ splitting of its degree listOfDegrees.
    ++ f is supposed not having any repeated factor (this is not checked).
factorSquareFree: (UP,List N,N) -> Factored UP
    ++ factorSquareFree(p,listOfDegrees,r) factorizes the polynomial p using
    ++ the single factor bound algorithm, knowing that p has for possible
    ++ splitting of its degree listOfDegrees and that p has at least r
    ++ factors.
    ++ f is supposed not having any repeated factor (this is not checked).
factorSquareFree: (UP,N,N) -> Factored UP
    ++ factorSquareFree(p,d,r) factorizes the polynomial p using the single
    ++ factor bound algorithm, knowing that d divides the degree of all
    ++ factors of p and that p has at least r factors.
    ++ f is supposed not having any repeated factor (this is not checked).
factorOfDegree: (P,UP) -> Union(UP,"failed")
    ++ factorOfDegree(d,p) returns a factor of p of degree d.
factorOfDegree: (P,UP,N) -> Union(UP,"failed")
    ++ factorOfDegree(d,p,r) returns a factor of p of degree
    ++ d knowing that p has at least r factors.
factorOfDegree: (P,UP,List N) -> Union(UP,"failed")
    ++ factorOfDegree(d,p,listOfDegrees) returns a factor
    ++ of p of degree d knowing that p has for possible splitting of its
    ++ degree listOfDegrees.
factorOfDegree: (P,UP,List N,N) -> Union(UP,"failed")
    ++ factorOfDegree(d,p,listOfDegrees,r) returns a factor

```

```

++ of p of degree d knowing that p has for possible splitting of its
++ degree listOfDegrees, and that p has at least r factors.
factorOfDegree: (P,UP,List N,N,Boolean) -> Union(UP,"failed")
++ factorOfDegree(d,p,listOfDegrees,r,sqf) returns a
++ factor of p of degree d knowing that p has for possible splitting of
++ its degree listOfDegrees, and that p has at least r factors.
++ If \spad{sqf=true} the polynomial is assumed to be square free (i.e.
++ without repeated factors).
henselFact: (UP,Boolean) -> FinalFact
++ henselFact(p,sqf) returns the factorization of p, the result
++ is a Record such that \spad{contp=}content p,
++ \spad{factors=}List of irreducible factors of p with exponent.
++ If \spad{sqf=true} the polynomial is assumed to be square free (i.e.
++ without repeated factors).
btwFact: (UP,Boolean,Set N,N) -> FinalFact
++ btwFact(p,sqf,pd,r) returns the factorization of p, the result
++ is a Record such that \spad{contp=}content p,
++ \spad{factors=}List of irreducible factors of p with exponent.
++ If \spad{sqf=true} the polynomial is assumed to be square free (i.e.
++ without repeated factors).
++ pd is the \spadtype{Set} of possible degrees. r is a lower bound for
++ the number of factors of p. Please do not use this function in your
++ code because its design may change.

Exports ==> with
  monic?: UP -> Boolean
    ++ monic?(p) tests if p is monic (i.e. leading coefficient equal to 1).
```

```

unvectorise: Vector R -> UP
  ++ unvectorise(v) returns the polynomial which has for coefficients the
  ++ entries of v in the increasing order.
reverse: UP -> UP
  ++ reverse(p) returns the reverse polynomial of p.
scaleRoots: (UP,R) -> UP
  ++ scaleRoots(p,c) returns the polynomial which has c times the roots
  ++ of p.
shiftRoots: (UP,R) -> UP
  ++ shiftRoots(p,c) returns the polynomial which has for roots c added
  ++ to the roots of p.
degreePartition: Factored UP -> Multiset N
  ++ degreePartition(f) returns the degree partition (i.e. the multiset
  ++ of the degrees of the irreducible factors) of
  ++ the polynomial f.

(package GENEEZ GenExEuclid)≡
)abbrev package GENEEZ GenExEuclid
++ Author : P.Gianni.
++ January 1990
++ The equation \spad{Af+Bg=h} and its generalization to n polynomials
++ is solved for solutions over the R, euclidean domain.
++ A table containing the solutions of \spad{Af+Bg=x**k} is used.
++ The operations are performed modulus a prime
++ which are in principle big enough,
++ but the solutions are tested and, in case of failure, a hensel
++ lifting process is used to get to the right solutions.
++ It will be used in the factorization of multivariate polynomials
++ over finite field, with \spad{R=F[x]}.

GenExEuclid(R,BP) : C == T
where
  R : EuclideanDomain
  PI ==> PositiveInteger
  NNI ==> NonNegativeInteger
  BP : UnivariatePolynomialCategory R
  L ==> List

C == with
  reduction: (BP,R) -> BP
    ++ reduction(p,prime) reduces the polynomial p modulo prime of R.
    ++ Note: this function is exported only because it's conditional.
  compBound: (BP,L BP) -> NNI
    ++ compBound(p,lp)

```

```

    ++ computes a bound for the coefficients of the solution
    ++ polynomials.
    ++ Given a polynomial right hand side p,
    ++ and a list lp of left hand side polynomials.
    ++ Exported because it depends on the valuation.
tablePow : (NNI,R,L BP) -> Union(Vector(L BP),"failed")
    ++ tablePow(maxdeg,prime,lpol) constructs the table with the
    ++ coefficients of the Extended Euclidean Algorithm for lpol.
    ++ Here the right side is \spad{x**k}, for k less or equal to maxdeg.
    ++ The operation returns "failed" when the elements
    ++ are not coprime modulo prime.
solveid : (BP,R,Vector L BP) -> Union(L BP,"failed")
    ++ solveid(h,table) computes the coefficients of the
    ++ extended euclidean algorithm for a list of polynomials
    ++ whose tablePow is table and with right side h.

testModulus : (R, L BP) -> Boolean
    ++ testModulus(p,lp) returns true if the the prime p
    ++ is valid for the list of polynomials lp, i.e. preserves
    ++ the degree and they remain relatively prime.

++ Rationalization of several types of genus 0 integrands;

```

```

++ Author: Manuel Bronstein

```

```

++ Date Created: 11 October 1988

```

```

++ Date Last Updated: 24 June 1994

```

```

++ Description:

```

```

++ This internal package rationalises integrands on curves of the form:

```

```

++ \spad{y\^2 = a x\^2 + b x + c}

```

```

++ \spad{y\^2 = (a x + b) / (c x + d)}

```

```

++ \spad{f(x, y) = 0} where f has degree 1 in x

```

```

++ The rationalization is done for integration, limited integration,

```

```

++ extended integration and the risch differential equation;

```

```

++ Description:

++ GrayCode provides a function for efficiently running

++ through all subsets of a finite set, only changing one element

++ by another one.

GrayCode: public == private where

PI ==> PositiveInteger

I ==> Integer

V ==> Vector

public ==> with

```

nextSubsetGray: (V V I,PI) -> V V I
++ nextSubsetGray(ww,n) returns a vector {\em vv} whose components
++ have the following meanings:\begin{items}
++ \item {\em vv.1}: a vector of length n whose entries are 0 or 1. This
++   can be interpreted as a code for a subset of the set 1,...,n;
++   {\em vv.1} differs from {\em ww.1} by exactly one entry;
++ \item {\em vv.2.1} is the number of the entry of {\em vv.1} which
++   will be changed next time;
++ \item {\em vv.2.1 = n+1} means that {\em vv.1} is the last subset;
++   trying to compute nextSubsetGray(vv) if {\em vv.2.1 = n+1}
++   will produce an error!
++ \end{items}
++ The other components of {\em vv.2} are needed to compute
++ nextSubsetGray efficiently.
++ Note: this is an implementation of [Williamson, Topic II, 3.54,
++ p. 112] for the special case {\em r1 = r2 = ... = rn = 2};
++ Note: nextSubsetGray produces a side-effect, i.e.
++ {\em nextSubsetGray(vv)} and {\em vv := nextSubsetGray(vv)}
++ will have the same effect.

```

```

firstSubsetGray: PI -> V V I

`<GroebnerFactorizationPackage.help>≡`

```
=====
GroebnerFactorizationPackage examples
=====
```

Solving systems of polynomial equations with the Groebner basis algorithm can often be very time consuming because, in general, the algorithm has exponential run-time. These systems, which often come from concrete applications, frequently have symmetries which are not taken advantage of by the algorithm. However, it often happens in this case that the polynomials which occur during the Groebner calculations are reducible. Since Axiom has an excellent polynomial factorization algorithm, it is very natural to combine the Groebner and factorization algorithms.

GroebnerFactorizationPackage exports the `groebnerFactorize` operation which implements a modified Groebner basis algorithm. In this algorithm, each polynomial that is to be put into the partial list of the basis is first factored. The remaining calculation is split into as many parts as there are irreducible factors. Call these factors p_1, \dots, p_N . In the branches corresponding to p_2, \dots, p_N , the factor p_1 can be divided out, and so on. This package also contains operations that allow you to specify the polynomials that are not zero on the common roots of the final Groebner basis.

Here is an example from chemistry. In a theoretical model of the cyclohexan C_6H_{12} , the six carbon atoms each sit in the center of gravity of a tetrahedron that has two hydrogen atoms and two carbon atoms at its corners. We first normalize and set the length of each edge to 1. Hence, the distances of one fixed carbon atom to each of its immediate neighbours is 1. We will denote the distances to the other three carbon atoms by x , y and z .

A. Dress developed a theory to decide whether a set of points and distances between them can be realized in an n -dimensional space. Here, of course, we have $n = 3$.

```
mfzn : SQMATRIX(6,DMP([x,y,z],Fraction INT)) := _
[ [0,1,1,1,1,1], [1,0,1,8/3,x,8/3], [1,1,0,1,8/3,y], _
  [1,8/3,1,0,1,8/3], [1,x,8/3,1,0,1], [1,8/3,y,8/3,1,0] ]
+0 1 1 1 1 1+
|           |
|           8   8|
|1  0  1  -  x  -|
|           3   3|
|           |
```

$$\begin{aligned}
 & \begin{vmatrix} & & & 8 & \\ 1 & 1 & 0 & 1 & -y \\ & & & 3 & \\ & & & & \\ & 8 & & & 8 \\ 1 & -1 & 0 & 1 & - \\ & 3 & & & 3 \\ & & & & \\ & & 8 & & \\ 1 & x & -1 & 0 & 1 \\ & & 3 & & \\ & & & & \\ & 8 & & 8 & \\ 1 & -y & -1 & 0 & \\ + & 3 & & 3 & + \end{vmatrix} \\
 & + \begin{vmatrix} & & & 8 & \\ 1 & 1 & 0 & 1 & -y \\ & & & 3 & \\ & & & & \\ & 8 & & & 8 \\ 1 & -1 & 0 & 1 & - \\ & 3 & & & 3 \\ & & & & \\ & & 8 & & \\ 1 & x & -1 & 0 & 1 \\ & & 3 & & \\ & & & & \\ & 8 & & 8 & \\ 1 & -y & -1 & 0 & \\ + & 3 & & 3 & + \end{vmatrix}
 \end{aligned}$$

Type: SquareMatrix(6,DistributedMultivariatePolynomial([x,y,z],
Fraction Integer))

For the cyclohexan, the distances have to satisfy this equation.

```

eq := determinant mfzn
      2 2    22 2    25 2    22    2    388      250      25 2    250      14575
    - x y  + -- x y - -- x  + -- x y  - --- x y - --- x - -- y  - --- y + -----
      3          9          3          9          27          9          27          81
Type: DistributedMultivariatePolynomial([x,y,z],Fraction Integer)

```

They also must satisfy the equations given by cyclic shifts of the indeterminates.

```

$$\left[x - \frac{19}{3}, y + \frac{5}{3}, z + \frac{5}{3} \right]$$

Type: List List DistributedMultivariatePolynomial([x,y,z],Fraction Integer)

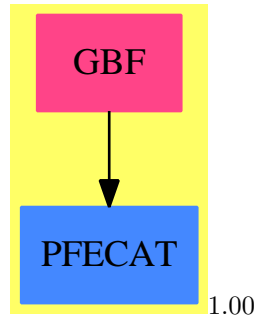

The union of the solutions of this list is the solution of our original problem. If we impose positivity conditions, we get two relevant ideals. One ideal is zero-dimensional, namely $x = y = z = 11/3$, and this determines the "boat" form of the cyclohexan. The other ideal is one-dimensional, which means that we have a solution space given by one parameter. This gives the "chair" form of the cyclohexan. The parameter describes the angle of the "back of the chair."

groebnerFactorize has an optional Boolean-valued second argument. When it is true partial results are displayed, since it may happen that the calculation does not terminate in a reasonable time. See the source code for GroebnerFactorizationPackage in groebf.spad.pamphlet for more details about the algorithms used.

++ Related Constructors:
++ Also See: GroebnerPackage, Ideal, IdealDecompositionPackage
++ AMS Classifications:
++ Keywords: groebner basis, groebner factorization, ideal decomposition
++ References:
++ Description:
++ \spadtype{GroebnerFactorizationPackage} provides the function
++ groebnerFactor" which uses the factorization routines of \Language{} to
++ factor each polynomial under consideration while doing the groebner basis
++ algorithm. Then it writes the ideal as an intersection of ideals
++ determined by the irreducible factors. Note that the whole ring may
++ occur as well as other redundancies. We also use the fact, that from the
++ second factor on we can assume that the preceding factors are
++ not equal to 0 and we divide all polynomials under considerations
++ by the elements of this list of "nonZeroRestrictions".
++ The result is a list of groebner bases, whose union of solutions
++ of the corresponding systems of equations is the solution of
++ the system of equation corresponding to the input list.
++ The term ordering is determined by the polynomial type used.
++ Suggested types include
++ \spadtype{DistributedMultivariatePolynomial},
++ \spadtype{HomogeneousDistributedMultivariatePolynomial},
++ \spadtype{GeneralDistributedMultivariatePolynomial}.

=====
groebner examples
=====
```

Example to call groebner:

```
s1:DMP[w,p,z,t,s,b]RN:= 45*p + 35*s - 165*b - 36
s2:DMP[w,p,z,t,s,b]RN:= 35*p + 40*z + 25*t - 27*s
s3:DMP[w,p,z,t,s,b]RN:= 15*w + 25*p*s + 30*z - 18*t - 165*b**2
s4:DMP[w,p,z,t,s,b]RN:= -9*w + 15*p*t + 20*z*s
s5:DMP[w,p,z,t,s,b]RN:= w*p + 2*z*t - 11*b**3
s6:DMP[w,p,z,t,s,b]RN:= 99*w - 11*b*s + 3*b**2
s7:DMP[w,p,z,t,s,b]RN:= b**2 + 33/50*b + 2673/10000
```

```
sn7:=[s1,s2,s3,s4,s5,s6,s7]
```

```
groebner(sn7,info)
```

groebner calculates a minimal Groebner Basis
all reductions are TOTAL reductions

To get the reduced critical pairs do:

```
groebner(sn7,"redcrit")
```

You can get other information by calling:

```
groebner(sn7,"info")
```

which returns:

```
ci => Leading monomial for critpair calculation
tci => Number of terms of polynomial i
cj => Leading monomial for critpair calculation
tcj => Number of terms of polynomial j
c => Leading monomial of critpair polynomial
tc => Number of terms of critpair polynomial
rc => Leading monomial of redcritpair polynomial
trc => Number of terms of redcritpair polynomial
tF => Number of polynomials in reduction list F
tD => Number of critpairs still to do
```

groebner normalForm

(package GB GroebnerPackage)≡

)abbrev package GB GroebnerPackage

++ Authors: Gebauer, Trager

++ Date Created: 12-1-86

++ Date Last Updated: 2-28-91

++ Basic Functions: groebner normalForm

++ Related Constructors: Ideal, IdealDecompositionPackage

++ Also See:

++ AMS Classifications:

++ Keywords: groebner basis, polynomial ideal

++ References:

++ Description: \spadtype{GroebnerPackage} computes groebner

++ bases for polynomial ideals. The basic computation provides

++ a distinguished set of generators for polynomial ideals over fields.

++ This basis allows an easy test for membership: the operation \spadfun{normalForm}

++ returns zero on ideal members. When the provided coefficient domain, Dom,

++ is not a field, the result is equivalent to considering the extended

++ ideal with \spadtype{Fraction(Dom)} as coefficients, but considerably more efficient

++ since all calculations are performed in Dom. Additional argument "info" and "redcrit"

++ can be given to provide incremental information during

++ computation. Argument "info" produces a computational summary for each s-polynomial.

++ Argument "redcrit" prints out the reduced critical pairs. The term ordering

++ is determined by the polynomial type used. Suggested types include

++ \spadtype{DistributedMultivariatePolynomial},

++ \spadtype{HomogeneousDistributedMultivariatePolynomial},

++ \spadtype{GeneralDistributedMultivariatePolynomial}.

reducing the degree of the polynomials

The degree of `poly3` is governed by $(a_0 + x_m a_1)^{x_m}$. Therefore, we substitute $A - x_m a_1$ for a_0 , which reduces the degree in a_1 by $x_m - x_{i+1}$.

```

```

Order and Degree

The following expressions for order and degree of the resultants `res1` and `res2` in `guessExpRatAux` were first guessed – partially with the aid of `guessRat`, and then proven to be correct.

```

<implementation: Guess - guessExpRat - Order and Degree>≡
ord1(x: List Integer, i: Integer): Integer ==
  n := #x - 3 - i
  x.(n+1)*reduce(_+, [x.j for j in 1..n], 0) + _
    2*reduce(_+, [reduce(_+, [x.k*x.j for k in 1..j-1], 0) _
      for j in 1..n], 0)

ord2(x: List Integer, i: Integer): Integer ==
  if zero? i then
    n := #x - 3 - i
    ord1(x, i) + reduce(_+, [x.j for j in 1..n], 0)*(x.(n+2)-x.(n+1))
  else
    ord1(x, i)

deg1(x: List Integer, i: Integer): Integer ==
  m := #x - 3
  (x.(m+3)+x.(m+1)+x.(1+i))*reduce(_+, [x.j for j in 2+i..m], 0) + _
    x.(m+3)*x.(m+1) + _
    2*reduce(_+, [reduce(_+, [x.k*x.j for k in 2+i..j-1], 0) _
      for j in 2+i..m], 0)

deg2(x: List Integer, i: Integer): Integer ==
  m := #x - 3
  deg1(x, i) + _
    (x.(m+3) + reduce(_+, [x.j for j in 2+i..m], 0)) * _
    (x.(m+2)-x.(m+1))

```

`evalResultant` evaluates the resultant of `p1` and `p2` at `d-o+1` points, so that we can recover it by interpolation.

```

<implementation: Guess - guessExpRat - evalResultant>≡
  evalResultant(p1: POLYS, p2: POLYS, o: Integer, d: Integer, va1: V, vA: V)_
  : List S ==
    res: List S := []
    d1 := degree(p1, va1)
    d2 := degree(p2, va1)
    lead: S
    for k in 1..d-o+1 repeat
      p1atk := univariate eval(p1, vA, k::S)
      p2atk := univariate eval(p2, vA, k::S)

```

It may happen, that the leading coefficients of one or both of the polynomials changes, when we evaluate it at k . In this case, we need to correct this by multiplying with the corresponding power of the leading coefficient of the other polynomial.

Consider the Sylvester matrix of the original polynomials. We want to evaluate it at $A = k$. If the first few leading coefficients of p_2 vanish, the first few columns of the Sylvester matrix have triangular shape, with the leading coefficient of p_1 on the diagonal. The same thing happens, if we exchange the roles of p_1 and p_2 , only that we have to take care of the sign, too.

```

<implementation: Guess - guessExpRat - evalResultant>+≡
    d1atk := degree p1atk
    d2atk := degree p2atk

    --      output("k: " string(k))$OutputPackage
    --      output("d1: " string(d1) " d1atk: " string(d1atk))$OutputPackage
    --      output("d2: " string(d2) " d2atk: " string(d2atk))$OutputPackage

    if d2atk < d2 then
        if d1atk < d1
        then lead := 0$S
        else lead := (leadingCoefficient p1atk)**((d2-d2atk)::NNI)
    else
        if d1atk < d1
        then lead := (-1$S)**d2 * (leadingCoefficient p2atk)**((d1-d1atk)::NNI)
        else lead := 1$S

    if zero? lead
    then res := cons(0, res)
    else res := cons(lead * (resultant(p1atk, p2atk)$SUP(S) exquo _
                                (k::S)**(o::NNI))::S,
                    res)

```

Since we also have an lower bound for the order of the resultant, we need to evaluate it only at $d - o + 1$ points. Furthermore, we can divide by k^o and still obtain a polynomial.

```

<implementation: Guess - guessExpRat - evalResultant>+≡
    reverse res

```

The main routine

```

      output(hconcat("degree ExpRat ">::OutputForm, i::OutputForm))
      $OutputPackage

```

Shouldn't we use the algorithm over `{\tt{}POLYS}` here? Strange enough, for polynomial interpolation, it is faster, but for rational interpolation *\emph{much}* slower. This should be investigated.

It seems that `{\tt{}maxDeg}` bounds the degree of the denominator, rather than the numerator? This is now added to the documentation of `{\tt{}maxDegree}`, it should make sense.

8.40.3 guessing rational functions with a binomial term

It is not clear whether one should take the model

```
\begin{equation*}
  \binom{a+bn}{n}q(n),
\end{equation*}
```

which includes rational functions, or

```
\begin{equation*}
  (a+bn)(a+bn+1)\dots (a+bn+n)q(n).
\end{equation*}
```

which includes rational functions times $n!$. We choose the former, since dividing by $n!$ is a common normalisation. The question remains whether we should do the same for `\tt{guessExpRat}`.

(implementation: Guess - guessBinRat)≡

```
EXT ==> (Integer, V, V) -> FPOLYS
EXTEXPR ==> (Symbol, F, F) -> EXPRR

--      if debug(options)$GOPT0 then
--          output(hconcat("degree BinRat ">::OutputForm, i::OutputForm))
--          $OutputPackage

```

Shouldn't we use the algorithm over $\{\texttt{POLYS}\}$ here? Strange enough, for polynomial interpolation, it is faster, but for rational interpolation *much* slower. This should be investigated.

It seems that $\{\texttt{maxDeg}\}$ bounds the degree of the denominator, rather than the numerator? This is now added to the documentation of $\{\texttt{maxDegree}\}$, it should make sense.

```

```

Streams

In this section we define some functions that provide streams for `HermitePade`.

The following three functions transform a partition `l` into a product of derivatives of `f`, using the given operators. We need to provide the same functionality for expressions, series and series with a transcendental element. Only for expressions we do not provide a version using the Hadamard product, although it would be quite easy to define an appropriate operator on expressions.

A partition $(\lambda_1^{p_1}, \lambda_2^{p_2}, \dots)$ is transformed into the expression $(f^{(\lambda_1-1)})^{p_1} (f^{(\lambda_2-1)})^{p_2} \dots$, i.e., the size of the part is interpreted as derivative, the exponent as power.

          for part in ll]

    reduce(hadamard$UFPS1(SUP F), fl)

```

It is not clear whether we should ‘prefer’ shifting and differentiation over powering. Currently, we produce the stream

$$\begin{array}{cccccccc} \emptyset & 1 & 11 & 2 & 111 & 21 & 3 & 1111 \\ 1 & f & f^2 & f' & f^3 & ff' & f'' & f^4 \dots \end{array}$$

Maybe it would be better to produce

$$\begin{array}{cccccccc} \emptyset & 1 & 2 & 11 & 3 & 21 & 111 & 4 \\ 1 & f & f' & f^2 & f'' & ff' & f^3 & f''' \dots \end{array}$$

instead, i.e., to leave the partitions unconjugated. Note however, that shifting and differentiation decrease the number of valid terms, while powering does not.

Note that we conjugate all partitions at the very end of the following procedure...

(implementation: Guess - Hermite-Pade - Streams)+≡

```
FilteredPartitionStream(options: LGOPT): Stream List Integer ==
  maxD := 1+maxDerivative(options)$GOPT0
  maxP := maxPower(options)$GOPT0

  if maxD > 0 and maxP > -1 then
    s := partitions(maxD, maxP)$PartitionsAndPermutations
  else
    s1: Stream Integer := generate(inc, 1)$Stream(Integer)
    s2: Stream Stream List Integer
      := map(partitions(#1)$PartitionsAndPermutations, s1)
      $StreamFunctions2(Integer, Stream List Integer)
    s3: Stream List Integer
      := concat(s2)$StreamFunctions1(List Integer)

  -- s := cons([],
  --           select(((maxD = 0) or (first #1 <= maxD)) _
  --                 and ((maxP = -1) or (# #1 <= maxP)), s3))

  s := cons([],
            select(((maxD = 0) or (# #1 <= maxD)) _
                  and ((maxP = -1) or (first #1 <= maxP)), s3))

  s := conjugates(s)$PartitionsAndPermutations
  if homogeneous(options)$GOPT0 then rest s else s

-- for functions
ADEguessStream(f: UFPSF, partitions: Stream List Integer,
               DS: DIFFSPECS, D1: DIFFSPEC1): Stream UFPSF ==
  map(termAsUFPSF(f, #1, DS, D1), partitions)
  $StreamFunctions2(List Integer, UFPSF)
```

```

-- for coefficients, i.e., using the Hadamard product
ADEguessStream2(f: UFPSF, partitions: Stream List Integer,
                DS: DIFFSPECS, D1: DIFFSPEC1): Stream UFPSF ==
  map(termAsUFPSF2(f, #1, DS, D1), partitions)
  $StreamFunctions2(List Integer, UFPSF)

```

The entries of the following stream indicate how many terms we loose when applying one of the power and shift or differentiation operators. More precisely, the n^{th} entry of the stream takes into account all partitions up to index n . Thus, the entries of the stream are weakly increasing.

(implementation: Guess - Hermite-Pade - Streams)+≡

```

  $StreamFunctions2(List Integer, EXPRR)

```

Operators

We need to define operators that transform series for differentiation and shifting. We also provide operators for q -analogs. The functionality corresponding to powering and taking the Hadamard product is provided by the streams, see Section 8.40.4.

We have to provide each operator in three versions:

- for expressions,
- for series, and
- for series with an additional transcendental element.

The latter makes it possible to detect lazily whether a computed coefficient of a series is valid or not.

Furthermore, we have to define for each operator how to extract the coefficient of x^k in $z^l f(x)$, where multiplication with z is defined depending on the operator. Again, it is necessary to provide this functionality for expressions, series and series with a transcendental element.

Finally, we define a function that returns the diagonal elements $c_{k,k}$ in the expansion $\langle x^k \rangle z f(x) = \sum_{i=0}^k c_{k,i} \langle x^i \rangle f(x)$, and an expression that represents the constant term for the inhomogeneous case.

The Differentiation Setting In this setting, we have $zf(x) := xf(x)$.

(implementation: Guess - Hermite-Pade - Operators) \equiv

```
diffDX: DIFFSPECX
```

```
diffDX(expr, x, n) == D(expr, x, n)
```

```
diffDS: DIFFSPECS
```

```
diffDS(s, n) == D(s, n)
```

```
diffDSF: DIFFSPECsf
```

```
diffDSF(s, n) ==
```

```
-- I have to help the compiler here a little to choose the right signature...
```

```
  if SUP F has _*: (NonNegativeInteger, SUP F) -> SUP F
```

```
  then D(s, n)
```

The next three functions extract the coefficient of x^k in $z^l f(x)$. Only, for expressions, we rather need $\sum_{k \geq 0} \langle x^k \rangle z^l f(x)$, i.e., the function itself, which is by definition equal to $x^l f(x)$.

```

<implementation: Guess - Hermite-Pade - Operators>+≡

         diffA, diffAF, diffAX, diffC]$HPSPEC
    else
        error "Guess: guessADE supports only displayAsGF"
```

Shifting The shift operator transforms a sequence $u(k)$ into $u(k+1)$. We also provide operators `ShiftSXGF`, `ShiftAXGF` that act on the power series, as long as no powering is involved. In this case, shifting transforms $f(x)$ into $\frac{f(x)-f(0)}{x}$. Multiplication with z transforms the coefficients $u(n)$ of the series into $zu(n) := nu(n)$. The description in terms of power series is given by $xDf(x)$.

```

```

q -Shifting The q -shift also transforms $u(n)$ into $u(n+1)$, and we can reuse the corresponding functions of the previous paragraph. However, this time multiplication with z is defined differently: the coefficient of x^k in $zu(n)$ is $q^n u(n)$. We do not define the corresponding functionality for power series.

(implementation: Guess - Hermite-Pade - Operators)+≡

Extend the action to polynomials The following operation uses the given action of z on a function to multiply a f with a polynomial.

(implementation: Guess - Hermite-Pade - Operators)+≡

```
makeEXPRR(DAX: DIFFSPECAX, x: Symbol, p: SUP F, expr: EXPRR): EXPRR ==
  if zero? p then 0$EXPRR
  else
    coerce(leadingCoefficient p)::EXPRR * DAX(degree p, x, expr) _
    + makeEXPRR(DAX, x, reductum p, expr)
```

Utilities

`list2UFPSF` and `list2UFPSSUPF` transform the list passed to the guessing functions into a series. One might be tempted to transform the list into a polynomial instead, but the present approach makes computing powers and derivatives much cheaper, since, because of laziness, only coefficients that are actually used are computed.

The second of the two procedures augments the list with a transcendental element. This way we can easily check whether a coefficient is valid or not: if it contains the transcendental element, it depends on data we do not have. In other words, this transcendental element simply represents the $O(x^d)$, when d is the number of elements in the list.

(implementation: Guess - Hermite-Pade - Utilities)≡

```
list2UFPSF(list: List F): UFPSF == series(list::Stream F)$UFPSF

list2UFPSSUPF(list: List F): UFPSSUPF ==
  l := [e::SUP(F) for e in list for i in 0..]::Stream SUP F
  series(l)$UFPSSUPF + monomial(monomial(1,1)$SUP(F), #list)$UFPSSUPF
```

`SUPF2SUPSUPF` interprets each coefficient as a univariate polynomial.

(implementation: Guess - Hermite-Pade - Utilities)+≡

```
SUPF2SUPSUPF(p: SUP F): SUP SUP F ==
  map(#1::SUP F, p)$SparseUnivariatePolynomialFunctions2(F, SUP F)
```

`getListSUPF` returns the first `o` elements of the stream, each truncated after degree `deg`.

<implementation: Guess - Hermite-Pade - Utilities>+≡

```
UFPSF2SUPF(f: UFPSF, deg: NNI): SUP F ==
  makeSUP univariatePolynomial(f, deg)
```

```
getListSUPF(s: Stream UFPSF, o: NNI, deg: NNI): List SUP F ==
  map(UFPSF2SUPF(#1, deg), entries complete first(s, o))
  $ListFunctions2(UFPSF, SUP F)
```

```
S2EXPRR(s: S): EXPRR ==
  if F is S then
    coerce(s pretend F)@EXPRR
  else if F is Fraction S then
    coerce(s::Fraction(S))@EXPRR
  else error "Type parameter F should be either equal to S or equal _
    to Fraction S"
```

<implementation: Guess - guessInterpolate>

<implementation: Guess - guessInterpolate2>

<implementation: Guess - testInterpolant>

`guessInterpolate` calls the appropriate `generalInterpolation` from `FFFG`, for one vector of degrees, namely `eta`.

<implementation: Guess - guessInterpolate>≡

```
guessInterpolate(guessList: List SUP F, eta: List NNI, D: HPSPEC)
  : Matrix SUP S ==
  if F is S then
    vguessList: Vector SUP S := vector(guessList pretend List(SUP(S)))
    generalInterpolation((D.C)(reduce(_+, eta)), D.A,
      vguessList, eta)$FFFG(S, SUP S)
  else if F is Fraction S then
    vguessListF: Vector SUP F := vector(guessList)
    generalInterpolation((D.C)(reduce(_+, eta)), D.A,
      vguessListF, eta)$FFFGF(S, SUP S, SUP F)

  else error "Type parameter F should be either equal to S or equal _
    to Fraction S"
```

`guessInterpolate2` calls the appropriate `generalInterpolation` from `FFFG`, for all degree vectors with given `sumEta` and `maxEta`.

```

<implementation: Guess - guessInterpolate2>≡
  guessInterpolate2(guessList: List SUP F,
                    sumEta: NNI, maxEta: NNI,
                    D: HPSPEC): Stream Matrix SUP S ==
    if F is S then
      vguessList: Vector SUP S := vector(guessList pretend List(SUP(S)))
      generalInterpolation((D.C)(sumEta), D.A,
                          vguessList, sumEta, maxEta)
      $FFFG(S, SUP S)
    else if F is Fraction S then
      vguessListF: Vector SUP F := vector(guessList)
      generalInterpolation((D.C)(sumEta), D.A,
                          vguessListF, sumEta, maxEta)
      $FFFGF(S, SUP S, SUP F)

    else error "Type parameter F should be either equal to S or equal _
              to Fraction S"

```

`testInterpolant` checks whether `p` is really a solution.

```

<implementation: Guess - testInterpolant>≡
  testInterpolant(resi: List SUP S,
                  list: List F,
                  testList: List UFPSSUPF,
                  exprList: List EXPRR,
                  initials: List EXPRR,
                  guessDegree: NNI,
                  D: HPSPEC,
                  dummy: Symbol, op: BasicOperator, options: LGOPT)
  : Union("failed", Record(function: EXPRR, order: NNI)) ==

```

First we make sure it is not a solution we should have found already. Note that we cannot check this if `maxDegree` is set, in which case some initial solutions may have been overlooked.

```

<implementation: Guess - testInterpolant>+≡
  ((maxDegree(options)$GOPT0 = -1) and
   (allDegrees(options)$GOPT0 = false) and
   zero?(last resi))
  => return "failed"

```

Then we check all the coefficients that should be valid. We want the zero solution only, if the function is really zero. Without this test, every sequence ending with zero is interpreted as the zero sequence, since the factor in front of the only non-vanishing term can cancel everything else.

```

<implementation: Guess - testInterpolant>+≡
  nonZeroCoefficient: Integer := 0

  for i in 1..#resi repeat
    if not zero? resi.i then
      if zero? nonZeroCoefficient then
        nonZeroCoefficient := i
      else
        nonZeroCoefficient := 0
        break

```

We set `nonZeroCoefficient` to the only non zero coefficient or, if there are several, it is 0. It should not happen that all coefficients in `resi` vanish.

Check that not all coefficients in `{\tt{resi}}` can vanish simultaneously.

```

<implementation: Guess - testInterpolant>+≡
  if not zero? nonZeroCoefficient then
    (freeOf?(exprList.nonZeroCoefficient, name op)) => return "failed"

  for e in list repeat
    if not zero? e then return "failed"

```

We first deal with the case that there is only one non-vanishing coefficient in **resi**. If the only expression in **exprList** whose coefficient does not vanish does not contain the name of the generating function, or if there is a non-zero term in **list**, we reject the proposed solution.

```

<implementation: Guess - testInterpolant>+≡
  else
    resiSUPF := map(SUPF2SUPSUPF SUPS2SUPF #1, resi)
                $ListFunctions2(SUP S, SUP SUP F)

    iterate? := true;
    for d in guessDegree+1.. repeat
      c: SUP F := generalCoefficient(D.AF, vector testList,
                                   d, vector resiSUPF)
                $FFFG(SUP F, UFPSSUPF)

      if not zero? c then
        iterate? := ground? c
        break

    iterate? => return "failed"

```

Here we check for each degree `d` larger than `guessDegree` whether the proposed linear combination vanishes. When the first coefficient that does not vanish contains the transcendental element we accept the linear combination as a solution.

Finally, it seems that we have found a solution. Now we cancel the greatest common divisor of the equation. Note that this may take quite some time, it seems to be quicker to check `generalCoefficient` with the original `resi`.

If `S` is a `Field`, the `gcd` will always be 1. Thus, in this case we make the result monic.

```

<implementation: Guess - testInterpolant>+≡
  g: SUP S
  if S has Field
  then g := leadingCoefficient(find(not zero? #1, reverse resi)::SUP(S))::SUP(S)
  else g := gcd resi
  resiF := map(SUPS2SUPF((#1 exquo g)::SUP(S)), resi)
           $ListFunctions2(SUP S, SUP F)

  if debug(options)$GOPT0 then
    output(hconcat("trying possible solution ", resiF::OutputForm))
    $OutputPackage

-- transform each term into an expression

  ex: List EXPRR := [makeEXPRR(D.AX, dummy, p, e) _
                    for p in resiF for e in exprList]

-- transform the list of expressions into a sum of expressions

  res: EXPRR
  if displayAsGF(options)$GOPT0 then
    res := evalADE(op, dummy, variableName(options)$GOPT0::EXPRR,
                  indexName(options)$GOPT0::EXPRR,
                  numerator reduce(_+, ex),
                  reverse initials)
          $RecurrenceOperator(Integer, EXPRR)
    ord: NNI := 0

```

The main routine

The following is the main guessing routine, called by all others – except `guessExprat`.

(implementation: Guess - guessHPaux) ≡

```
guessHPaux(list: List F, D: HPSPEC, options: LGOPT): GUESSRESULT ==
  reslist: GUESSRESULT := []
```

```
  listDegree := #list-1-safety(options)$GOPT0
  if listDegree < 0 then return reslist
```

We do as if we knew only the coefficients up to and including degree `listDegree-safety`. Thus, if we have less elements of the sequence than `safety`, there remain no elements for guessing. Originally we demanded to have at least two elements for guessing. However, we want to be able to induce from $[c, c]$ that the function equals c with `safety` one. This is important if we apply, for example, `guessRat` recursively. In this case, `listDegree` equals zero.

(implementation: Guess - guessHPaux) + ≡

```
  a := functionName(options)$GOPT0
  op := operator a
  x := variableName(options)$GOPT0
  dummy := new$Symbol
```

```
  initials: List EXPRR := [coerce(e)@EXPRR for e in list]
```

We need to create several streams. Let P be the univariate power series whose first few elements are given by `list`. As an example, consider the differentiation setting. In this case, the elements of `guessS` consist of P differentiated and taken to some power. The elements of `degreeS` are integers, that tell us how many terms less than in `list` are valid in the corresponding element of `guessS`. The elements of `testS` are very similar to those of `guessS`, with the difference that they are derived from P with an transcendental element added, which corresponds to $O(x^d)$. Finally, the elements of `exprS` contain representations of the transformations applied to P as expressions.

I am not sure whether it is better to get rid of denominators in `{\tt{}list}` here or, as I currently do it, only in `{\tt{}generalInterpolation{\char36}FFFG}`. %\$
If we clear them at here, we cannot take advantage of factors that may appear only after differentiating or powering.

```
<implementation: Guess - guessHPaux>+≡
guessS  := (D.guessStream)(list2UFPSF list)
degreeS := D.degreeStream
testS   := (D.testStream)(list2UFPSSUPF list)
exprS   := (D.exprStream)(op(dummy::EXPRR)::EXPRR, dummy)
```

We call the number of terms of the linear combination its *order*. We consider linear combinations of at least two terms, since otherwise the function would have to vanish identically...

When proceeding in the stream `guessS`, it may happen that we loose valid terms. For example, when trying to find a linear ordinary differential equation, we are looking for a linear combination of f, f', f'', \dots . Suppose `listDegree` equals 2, i.e. we have

```
f           &= 1_0 + 1_1 x + 1_2 x^2\\
f^\prime    &= 1_1 + 2 1_2 x\\
f^{\prime\prime} &= 2 1_2.
```

Thus, each time we differentiate the series, we loose one term for guessing. Therefore, we cannot use the coefficient of x^2 of f'' for generating a linear combination. `guessDegree` contains the degree up to which all the generated series are correct, taking into account **safety**.

(implementation: Guess - guessHPaux)+≡

```
iterate?: Boolean := false -- this is necessary because the compiler
                             -- doesn't understand => "iterate" properly
                             -- the latter just leaves the current block, it
                             -- seems

for o in 2.. repeat
  empty? rest(guessS, (o-1)::NNI) => break
  guessDegree: Integer := listDegree-(degreeS.o)::Integer
  guessDegree < 0 => break
  if debug(options)$GOPT0 then
    output(hconcat("Trying order ", o::OutputForm))$OutputPackage
    output(hconcat("guessDegree is ", guessDegree::OutputForm))
      $OutputPackage
```

We now have to distinguish between the case where we try all combination of degrees and the case where we try only an (nearly) evenly distributed vector of degrees.

In the first case, `guessInterpolate2` is going to look at all degree vectors with `o` elements with total degree `guessDegree+1`. We give up as soon as the order `o` is greater than the number of available terms plus one. In the extreme case, i.e., when `o=guessDegree+2`, we allow for example constant coefficients for all terms of the linear combination. It seems that it is a bit arbitrary at what point we stop, however, we would like to be consistent with the evenly distributed case.

```
<implementation: Guess - guessHPaux>+≡
  if allDegrees(options)$GOPT0 then
    (o > guessDegree+2) => return reslist

    maxEta: Integer := 1+maxDegree(options)$GOPT0
    if maxEta = 0
      then maxEta := guessDegree+1
    else
```

In the second case, we first compute the number of parameters available for determining the coefficient polynomials. We have to take care of the fact, that HermitePade produces solutions with sum of degrees being one more than the sum of elements in `eta`.

```
<implementation: Guess - guessHPaux>+≡
  maxParams := divide(guessDegree::NNI+1, o)
  if debug(options)$GOPT0
    then output(hconcat("maxParams: ", maxParams::OutputForm))
      $OutputPackage
```

If we do not have enough parameters, we give up. We allow for at most one zero entry in the degree vector, because then there is one column that allows at least a constant term in each entry.

```
<implementation: Guess - guessHPaux>+≡
  if maxParams.quotient = 0 and maxParams.remainder < o-1
    then return reslist
```

If `maxDegree` is set, we skip the first few partitions, unless we cannot increase the order anymore.

I have no satisfactory way to determine whether we can increase the order or not.

```

<implementation: Guess - guessHPaux>+≡
  if ((maxDegree(options)$GOPT0 ~= -1) and
      (maxDegree(options)$GOPT0 < maxParams.quotient)) and
      not (empty? rest(guessS, o) or
          ((newGuessDegree := listDegree-(degreeS.(o+1))::Integer)
           < 0) or
          (((newMaxParams := divide(newGuessDegree::NNI+1, o+1))
            .quotient = 0) and
           (newMaxParams.remainder < o)))
  then iterate? := true
  else if ((maxDegree(options)$GOPT0 ~= -1) and
           (maxParams.quotient > maxDegree(options)$GOPT0))
  then
    guessDegree := o*(1+maxDegree(options)$GOPT0)-2
    eta: List NNI
    := [(if i < o
         then maxDegree(options)$GOPT0 + 1
         else maxDegree(options)$GOPT0)::NNI
        for i in 1..o]
  else eta: List NNI
    := [(if i <= maxParams.remainder
         then maxParams.quotient + 1
         else maxParams.quotient)::NNI for i in 1..o]

```

We distribute the parameters as evenly as possible. Is it better to have higher degrees at the end or at the beginning?

It remains to prepare `guessList`, which is the list of `o` power series polynomials truncated after degree `guessDegree`. Then we can call `HermitePade`.

`{\tt{maxDegree}}` should be handled differently, maybe: we should only pass as many coefficients to `{\tt{FFFG}}` as `{\tt{maxDegree}}` implies! That is, if we cannot increase the order anymore, we should decrease `{\tt{guessDegree}}` to `%$o\cdot {\tt{maxDegree}} - 2$` and set `{\tt{eta}}` accordingly. I might have to take care of `{\tt{allDegrees}}`, too.

```

8.40.5 guess – applying operators recursively

The main observation made by Christian Krattenthaler in designing his program Rate is the following: it occurs frequently that although a sequence of numbers is not generated by a rational function, the sequence of successive quotients is.

We slightly extend upon this idea, and apply recursively one or both of the two following operators:

Δ_n the differencing operator, transforming $f(n)$ into $f(n) - f(n - 1)$, and

Q_n the operator that transforms $f(n)$ into $f(n)/f(n - 1)$.

(implementation: Guess - guess)≡

```

++ Description:
++ This is an inner package for factoring multivariate polynomials
++ over various coefficient domains in characteristic 0.
++ The univariate factor operation is passed as a parameter.
++ Multivariate hensel lifting is used to lift the univariate
++ factorization

-- Both exposed functions call mFactor. This deals with issues such as
-- monomial factors, contents, square-freeness etc., then calls intfact.
-- This uses intChoose to find a "good" evaluation and factorise the
-- corresponding univariate, and then uses MultivariateLifting to find
-- the multivariate factors.

InnerNormalBasisFieldFunctions(GF): Exports == Implementation where
  GF      : FiniteFieldCategory      -- the ground field

  PI      ==> PositiveInteger
  NNI     ==> NonNegativeInteger
  I       ==> Integer
  SI      ==> SingleInteger
  SUP     ==> SparseUnivariatePolynomial
  VGF     ==> Vector GF
  M       ==> Matrix
  V       ==> Vector
  L       ==> List
  OUT     ==> OutputForm
  TERM    ==> Record(value:GF,index:SI)
  MM      ==> ModMonic(GF,SUP GF)

Exports ==> with

  setFieldInfo: (V L TERM,GF) -> Void
    ++ setFieldInfo(m,p) initializes the field arithmetic, where m is
    ++ the multiplication table and p is the respective normal element
    ++ of the ground field GF.
  random      : PI          -> VGF
    ++ random(n) creates a vector over the ground field with random entries.
  index      : (PI,PI)     -> VGF
    ++ index(n,m) is a index function for vectors of length n over
    ++ the ground field.
  pol        : VGF         -> SUP GF
    ++ pol(v) turns the vector \spad{[v0,...,vn]} into the polynomial
    ++ \spad{v0+v1*x+ ... + vn*x**n}.
  xn         : NNI         -> SUP GF
    ++ xn(n) returns the polynomial \spad{x**n-1}.
  dAndcExp   : (VGF,NNI,SI) -> VGF
    ++ dAndcExp(v,n,k) computes \spad{v**e} interpreting v as an element of
    ++ normal basis field. A divide and conquer algorithm similar to the
    ++ one from D.R.Stinson,
    ++ "Some observations on parallel Algorithms for fast exponentiation in
    ++ GF(2^n)", Siam J. Computation, Vol.19, No.4, pp.711-717, August 1990
    ++ is used. Argument k is a parameter of this algorithm.
  repSq      : (VGF,NNI)   -> VGF
    ++ repSq(v,e) computes \spad{v**e} by repeated squaring,
    ++ interpreting v as an element of a normal basis field.
  expPot     : (VGF,SI,SI) -> VGF
    ++ expPot(v,e,d) returns the sum from \spad{i = 0} to
    ++ \spad{e - 1} of \spad{v**(q**i*d)}, interpreting

```

```

++ v as an element of a normal basis field and where q is
++ the size of the ground field.
++ Note: for a description of the algorithm, see T.Itoh and S.Tsujii,
++ "A fast algorithm for computing multiplicative inverses in GF(2^m)
++ using normal bases",
++ Information and Computation 78, pp.171-177, 1988.
qPot      : (VGF,I)      -> VGF
++ qPot(v,e) computes \spad{v**(q**e)}, interpreting v as an element of
++ normal basis field, q the size of the ground field.
++ This is done by a cyclic e-shift of the vector v.

C == with

charpol : MK -> SUK
++ charpol(m) computes the characteristic polynomial of a matrix
++ m with entries in K.
++ This function returns a polynomial
++ over K, while the general one (that is in EiegenPackage) returns
++ Fraction P K

solve1 : (SUK, Par) -> List F
++ solve1(pol, eps) finds the roots of the univariate polynomial
++ polynomial pol to precision eps. If K is \spad{Fraction Integer}
++ then only the real roots are returned, if K is
++ \spad{Complex Fraction Integer} then all roots are found.

innerEigenvectors : (MK,Par,UFactor) -> List(outForm)
++ innerEigenvectors(m,eps,factor) computes explicitly
++ the eigenvalues and the correspondent eigenvectors
++ of the matrix m. The parameter eps determines the type of
++ the output, factor is the univariate factorizer to be used
++ to reduce the characteristic polynomial into irreducible factors.

=====
```

The `binomial(n, r)` returns the number of subsets of `r` objects taken among `n` objects, i.e. $n!/(r! * (n-r)!)$

The binomial coefficients are the coefficients of the series expansion of a power of a binomial, that is

$$\sum_{k=0}^n \binom{n}{k} x^k = (1+x)^n$$

This leads to the famous pascal triangle. First we expose the `OutputForm` domain, which is normally hidden, so we can use it to format the lines.

```
)set expose add constructor OutputForm
```

Next we define a function that will output the list of binomial coefficients right justified with proper spacing:

```
pascalRow(n) == [right(binomial(n,i),4) for i in 0..n]
```

and now we format the whole line so that it looks centered:

```
displayRow(n)==output center blankSeparate pascalRow(n)
```

and we compute the triangle

```
for i in 0..7 repeat displayRow i
```

giving the pretty result:

```
Compiling function pascalRow with type NonNegativeInteger -> List
OutputForm
Compiling function displayRow with type NonNegativeInteger -> Void
```

```

      1
     1 1
    1 2 1
   1 3 3 1
  1 4 6 4 1
 1 5 10 10 5 1

10.48.2 PollardSmallFactor

This is Brent's[?] optimization of Pollard's[?] rho factoring. Brent's algorithm is about 24 percent faster than Pollard's. Pollard's algorithm has complexity $O(p^{1/2})$ where p is the smallest prime factor of the composite number N .

Pollard's idea is based on the observation that two numbers x and y are congruent modulo p with probability 0.5 after $1.177 * \sqrt{p}$ numbers have been randomly chosen. If we try to factor n and p is a factor of n , then

$$1 < \gcd(|x - y|, n) \leq n$$

since p divides both $|x - y|$ and n .

Given a function f which generates a pseudo-random sequence of numbers we allow x to walk the sequence in order and y to walk the sequence at twice the rate. At each cycle we compute $\gcd(|x - y|, n)$. If this GCD ever equals n then $x = y$ which means that we have walked "all the way around the pseudo-random cycle" and we terminate with failure.

This algorithm returns failure on all primes but also fails on some composite numbers.

Quoting Brent's back-tracking idea:

The best-known algorithm for finding GCDs is the Euclidean algorithm which takes $O(\log N)$ times as long as one multiplication mod N . Pollard showed that most of the GCD computations in Floyd's algorithm could be dispensed with. ... The idea is simple: if P_F computes $GCD(z_1, N)$, $GCD(z_2, N)$, ..., then we compute

$$q_i = \prod_{j=1}^i z_j \pmod{N}$$

and only compute $GCD(q_i, N)$ when i is a multiple of m , where $\log N \ll m \ll N^{1/4}$. Since $q_{i+1} = q_i \times z_{i+1} \pmod{N}$, the work required for each GCD computation in algorithm P_F is effectively reduced to that for a multiplication mod N in the modified algorithm. The probability of the algorithm failing because $q_i = 0$ increases, so it is best not to choose m too large. This problem can be minimized by backtracking to the state after the previous GCD computation and setting $m = 1$.

Brent incorporates back-tracking, omits the random choice of u , and makes some minor modifications. His algorithm (p192-183) reads:

```

y := x0; r := 1; q := 1;
repeat x := y;
    for i := 1 to r do y := f(y); k := 0;

```

```

repeat  $ys := y$ ;
  for  $i := 1$  to  $\min(m, r - k)$  do
    begin  $y := f(y)$ ;  $q := q * |x - y| \bmod N$ 
    end;
     $G := \text{GCD}(q, N)$ ;  $k := k + m$ 
  until  $(k \geq r)$  or  $(G > 1)$ ;  $r := 2 * r$ 
until  $G > 1$ ;
if  $G = N$  then
  repeat  $ys := f(ys)$ ;  $G := \text{GCD}(|y - yx|, N)$ 
  until  $G > 1$ ;
if  $G = N$  then failure else success

```

Here we use the function

$$(y * y + 5 :: I) \bmod n$$

as our pseudo-random sequence with a random starting value for y.

One possible optimization to explore is to keep a hash table for the computed values of the function $y_{i+1} := f(y_i)$ since we effectively walk the sequence several times. And we walk the sequence in a loop many times. But because we are generating a very large number of numbers the array can be a simple array of fixed size that captures the last n values. So if we make a fixed array F of, say 2^q elements we can store $f(y_i)$ in $F[y_i \bmod 2^q]$.

One property that this algorithm assumes is that the function used to generate the numbers has a long, hopefully complete, period. It is not clear that the recommended function has that property.

```

(package INTFACT IntegerFactorizationPackage)+≡

```

10.48.3 BasicSieve

We create a list of prime numbers up to the limit given. The prior code used a circular list but tests of that list show that on average more than 50% of the required prime numbers. Overall this is a small percentage of the time needed to factor.

This loop uses three pieces of information

1. n which is the number we are testing
2. d which is the current prime to test
3. lim which is the upper limit of the primes to test

We loop d over the list of primes. If the remaining number n is smaller than the square of d then n must be prime and if it is not one, we add it to the list of primes. If the remaining number is larger than the square of d we remove all factors of d, reducing n each time. Then we add a record of the new factor and its multiplicity, m. We continue the loop until we run out of primes.

Annoyingly enough, primes does not return an ordered list so we fix this.

The sieve works up to a given limit, reducing out the factors that it finds. If it can find all of the factors then it returns a factored result where the first element is the unit 1. If there is still a part of the number unfactored it returns the number and a list of the factors found and their multiplicity.

Basically we just loop thru the prime factors checking to see if they are a component of the number, n. If so, we remove the factor from the number n (possibly m times) and continue thru the list of primes.

(package INTFACT IntegerFactorizationPackage)+≡

```
BasicSieve(n, lim) ==
  p:=primes(1:I,lim:I)$IntegerPrimesPackage(I)
  l:List(I) := append([first p],reverse rest p)
  ls := empty()$List(FFE)
  for d in l repeat
    if n<d*d then
      if n>1 then ls := concat_!(ls, ["prime",n,1]$FFE)
      return makeFR(1, ls)
    for m in 0.. while zero?(n rem d) repeat n := n quo d
    if m>0 then ls := concat_!(ls, ["prime",d,convert m]$FFE)
  makeFR(n,ls)
```

10.48.4 BasicMethod

```
<package INTFACT IntegerFactorizationPackage>+≡  
BasicMethod n ==  
  u:I  
  if n<0 then (m := -n; u := -1)  
    else (m := n; u := 1)  
  x := BasicSieve(m, 1 + approxSqrt m)  
  makeFR(u, factorList x)
```

10.48.5 factor

The factor function is many orders of magnitude slower than the results of other systems. A posting on sci.math.symbolic showed that NTL could factor the final value (t6) in about 11 seconds. Axiom takes about 8 hours.

```
a1:=101
a2:=109
t1:=a1*a2
factor t1
```

```
a3:=21525175387
t2:=t1*a3
factor t2
```

```
a4:=218301576858349
t3:=t2*a4
factor t3
```

```
a5:=13731482973783137
t4:=t3*a5
factor t4
```

```
a6:=23326138687706820109
t5:=t4*a6
factor t5
```

```
a7:=4328240801173188438252813716944518369161
t6:=t5*a7
factor t6
```

```
(package INTFACT IntegerFactorizationPackage)+≡

`<IntegerLinearDependence.help>≡`

```
=====
IntegerLinearDependence examples
=====
```

The elements v_1, \dots, v_N of a module M over a ring R are said to be linearly dependent over R if there exist c_1, \dots, c_N in R , not all 0, such that $c_1 v_1 + \dots + c_N v_N = 0$. If such c_i 's exist, they form what is called a linear dependence relation over R for the v_i 's.

The package `IntegerLinearDependence` provides functions for testing whether some elements of a module over the integers are linearly dependent over the integers, and to find the linear dependence relations, if any.

Consider the domain of two by two square matrices with integer entries.

```
M := SQMATRIX(2,INT)
    SquareMatrix(2,Integer)
                        Type: Domain
```

Now create three such matrices.

```
m1: M := squareMatrix matrix [ [1, 2], [0, -1] ]
      +1  2 +
      |    |
      +0  -1+
                        Type: SquareMatrix(2,Integer)
```

```
m2: M := squareMatrix matrix [ [2, 3], [1, -2] ]
      +2  3 +
      |    |
      +1  -2+
                        Type: SquareMatrix(2,Integer)
```

```
m3: M := squareMatrix matrix [ [3, 4], [2, -3] ]
      +3  4 +
      |    |
      +2  -3+
                        Type: SquareMatrix(2,Integer)
```

This tells you whether m_1 , m_2 and m_3 are linearly dependent over the integers.

```
linearlyDependentOverZ? vector [m1, m2, m3]
true
                        Type: Boolean
```

Since they are linearly dependent, you can ask for the dependence relation.

```
c := linearDependenceOverZ vector [m1, m2, m3]
[1,- 2,1]
Type: Union(Vector Integer,...)
```

This means that the following linear combination should be 0.

```
c.1 * m1 + c.2 * m2 + c.3 * m3
+0  0+
|    |
+0  0+
Type: SquareMatrix(2,Integer)
```

When a given set of elements are linearly dependent over R , this also means that at least one of them can be rewritten as a linear combination of the others with coefficients in the quotient field of R .

To express a given element in terms of other elements, use the operation `solveLinearlyOverQ`.

```
solveLinearlyOverQ(vector [m1, m3], m2)
1 1
[-,-]
2 2
Type: Union(Vector Fraction Integer,...)
```

(IntegerNumberTheoryFunctions.help)≡

```
=====
IntegerNumberTheoryFunctions examples
=====
```

The IntegerNumberTheoryFunctions package contains a variety of operations of interest to number theorists. Many of these operations deal with divisibility properties of integers. (Recall that an integer a divides an integer b if there is an integer c such that $b = a * c$.)

The operation `divisors` returns a list of the divisors of an integer.

```
div144 := divisors(144)
      [1,2,3,4,6,8,9,12,16,18,24,36,48,72,144]
                        Type: List Integer
```

You can now compute the number of divisors of 144 and the sum of the divisors of 144 by counting and summing the elements of the list we just created.

```
#(div144)
      15
                        Type: PositiveInteger
```

```
reduce(+,div144)
      403
                        Type: PositiveInteger
```

Of course, you can compute the number of divisors of an integer n , usually denoted $d(n)$, and the sum of the divisors of an integer n , usually denoted $\sigma(n)$, without ever listing the divisors of n .

In Axiom, you can simply call the operations `numberOfDivisors` and `sumOfDivisors`.

```
numberOfDivisors(144)
      15
                        Type: PositiveInteger
```

```
sumOfDivisors(144)
      403
                        Type: PositiveInteger
```

The key is that $d(n)$ and $\sigma(n)$ are "multiplicative functions." This means that when n and m are relatively prime, that is, when n and m have no prime factor in common, then $d(nm) = d(n) d(m)$ and

$\text{sigma}(nm) = \text{sigma}(n) \text{sigma}(m)$. Note that these functions are trivial to compute when n is a prime power and are computed for general n from the prime factorization of n . Other examples of multiplicative functions are $\text{sigma}_k(n)$, the sum of the k -th powers of the divisors of n and $\text{varphi}(n)$, the number of integers between 1 and n which are prime to n . The corresponding Axiom operations are called `sumOfKthPowerDivisors` and `eulerPhi`.

An interesting function is $\mu(n)$, the Moebius μ function, defined as follows: $\mu(1) = 1$, $\mu(n) = 0$, when n is divisible by a square, and $\mu = (-1)^k$, when n is the product of k distinct primes. The corresponding Axiom operation is `moebiusMu`. This function occurs in the following theorem:

Theorem: (Moebius Inversion Formula):

Let $f(n)$ be a function on the positive integers and let $F(n)$ be defined by

$$F(n) = \sum_{d|n} f(d)$$

the sum of $f(n)$ over $d|n$ where the sum is taken over the positive divisors of n . Then the values of $f(n)$ can be recovered from the values of $F(n)$: $f(n) = \sum_{d|n} \mu(d) F(n/d)$ where again the sum is taken over the positive divisors of n .

When $f(n) = 1$, then $F(n) = d(n)$. Thus, if you sum $\mu(d) \cdot d(n/d)$ over the positive divisors d of n , you should always get 1.

```
f1(n)==reduce(+,[moebiusMu(d)*numberOfDivisors(quo(n,d))_
for d in divisors(n)])
```

Type: Void

```
f1(200)
```

```
1
```

Type: PositiveInteger

```
f1(846)
```

```
1
```

Type: PositiveInteger

Similarly, when $f(n) = n$, then $F(n) = \text{sigma}(n)$. Thus, if you sum $\mu(d) \cdot \text{sigma}(n/d)$ over the positive divisors d of n , you should always get n .

```
f2(n) == reduce(+,[moebiusMu(d) * sumOfDivisors(quo(n,d))_
for d in divisors(n)])
```

Type: Void

```
f2(200)
```

```
200
```

Type: PositiveInteger

```
f2(846)
846
```

Type: PositiveInteger

The Fibonacci numbers are defined by

$F(1) = F(2) = 1$ and
 $F(n) = F(n-1) + F(n-2)$ for $n = 3, 4, \dots$

The operation fibonacci computes the n-th Fibonacci number.

```
fibonacci(25)
75025
```

Type: PositiveInteger

```
[fibonacci(n) for n in 1..15]
[1,1,2,3,5,8,13,21,34,55,89,144,233,377,610]
Type: List Integer
```

Fibonacci numbers can also be expressed as sums of binomial coefficients.

```
fib(n) == reduce(+,[binomial(n-1-k,k) for k in 0..quo(n-1,2)])
Type: Void
```

```
fib(25)
75025
```

Type: PositiveInteger

```
[fib(n) for n in 1..15]
[1,1,2,3,5,8,13,21,34,55,89,144,233,377,610]
Type: List Integer
```

Quadratic symbols can be computed with the operations legendre and jacobi. The Legendre symbol a/p is defined for integers a and p with p an odd prime number. By definition,

$(a/p) = +1$, when a is a square (mod p),
 $(a/p) = -1$, when a is not a square (mod p), and
 $(a/p) = 0$, when a is divisible by p .

You compute (a/p) via the command legendre(a,p).

```
legendre(3,5)
- 1
```

Type: Integer

```

legendre(23,691)
- 1

```

Type: Integer

The Jacobi symbol (a/n) is the usual extension of the Legendre symbol, where n is an arbitrary integer. The most important property of the Jacobi symbol is the following: if K is a quadratic field with discriminant d and quadratic character χ , then $\chi(n) = (d/n)$. Thus, you can use the Jacobi symbol to compute, say, the class numbers of imaginary quadratic fields from a standard class number formula.

This function computes the class number of the imaginary quadratic field with discriminant d .

```

h(d) == quo(reduce(+,[jacobi(d,k) for k in 1..quo(-d, 2)]),2-jacobi(d,2))
Type: Void

```

```

h(-163)
1

```

Type: PositiveInteger

```

h(-499)
3

```

Type: PositiveInteger

```

h(-1832)
26

```

Type: PositiveInteger

```

=====
The inverse function
=====

```

The inverse function is derived from the Extended Euclidean Algorithm. If we divide one integer by another nonzero integer we get an integer quotient plus a remainder which is, in general, a rational number. For instance,

$$13/5 = 2 + 3/5$$

where 2 is the quotient and $3/5$ is the remainder.

If we multiply thru by the denominator of the remainder we get an answer in integer terms which no longer involves division:

$$13 = 2(5) + 3$$

This gives a method of dividing integers. Specifically, if a and b are

positive integers, there exist unique non-negative integers q and r so that

$$a = qb + r, \text{ where } 0 \leq r < b$$

q is called the quotient and r the remainder.

The greatest common divisor of integers a and b , denoted by $\gcd(a, b)$, is the largest integer that divides (without remainder) both a and b . So, for example:

$$\begin{aligned}\gcd(15, 5) &= 5, \\ \gcd(7, 9) &= 1, \\ \gcd(12, 9) &= 3, \\ \gcd(81, 57) &= 3.\end{aligned}$$

The gcd of two integers can be found by repeated application of the division algorithm, this is known as the Euclidean Algorithm. You repeatedly divide the divisor by the remainder until the remainder is 0. The gcd is the last non-zero remainder in this algorithm. The following example shows the algorithm.

Finding the gcd of 81 and 57 by the Euclidean Algorithm:

$$\begin{aligned}81 &= 1(57) + 24 \\ 57 &= 2(24) + 9 \\ 24 &= 2(9) + 6 \\ 9 &= 1(6) + 3 \\ 6 &= 2(3) + 0\end{aligned}$$

So the greatest common divisor, the $\gcd(81, 57)=3$.

If the $\gcd(a, b) = r$ then there exist integers s and t so that

$$s(a) + t(b) = r$$

By back substitution in the steps in the Euclidean Algorithm, it is possible to find these integers s and t . We shall do this with the above example:

Starting with the next to last line, we have:

$$3 = 9 - 1(6)$$

From the line before that, we see that $6 = 24 - 2(9)$, so:

$$3 = 9 - 1(24 - 2(9)) = 3(9) - 1(24)$$

From the line before that, we have $9 = 57 - 2(24)$, so:

$$3 = 3(57 - 2(24)) - 1(24) = 3(57) - 7(24)$$

And, from the line before that $24 = 81 - 1(57)$, giving us:

$$3 = 3(57) - 7(81 - 1(57)) = 10(57) - 7(81)$$

So we have found $s = -7$ and $t = 10$.

The Extended Euclidean Algorithm computes the $\text{GCD}(a,b)$ and the values for s and t .

Suppose we were doing arithmetics modulo 26 and we needed to find the inverse of a number mod 26. This turned out to be a difficult task (and not always possible). We observed that a number x had an inverse mod 26 (i.e., a number y so that $xy = 1 \bmod 26$) if and only if $\text{gcd}(x,26) = 1$. In the general case the inverse of x exists if and only if $\text{gcd}(x, n) = 1$ and if it exists then there exist integers s and t so that

$$sx + tn = 1$$

But this says that $sx = 1 + (-t)n$, or in other words,

$$sx \equiv 1 \bmod n$$

So, s (reduced mod n if need be) is the inverse of x mod n . The extended Euclidean algorithm calculates s efficiently.

```
=====
Finding the inverse mod n
=====
```

We will number the steps of the Euclidean algorithm starting with step 0. The quotient obtained at step i will be denoted by q_i and an auxillary number, s_i . For the first two steps, the value of this number is given:

$$\begin{aligned} s(0) &= 0 \text{ and} \\ s(1) &= 1. \end{aligned}$$

For the remainder of the steps, we recursively calculate

$$s(i) = s(i-2) - s(i-1) q(i-2) \bmod n$$

The algorithm starts by "dividing" n by x . If the last non-zero remainder occurs at step k , then if this remainder is 1, x has an inverse and it is $s(k+2)$. If the remainder is not 1, then x does not have an inverse.

For example, find the inverse of 15 mod 26.

Step 0: $26 = 1(15) + 11$ $s(0) = 0$
 Step 1: $15 = 1(11) + 4$ $s(1) = 1$
 Step 2: $11 = 2(4) + 3$ $s(2) = 0 - 1(1) \bmod 26 = 25$
 Step 3: $4 = 1(3) + 1$ $s(3) = 1 - 25(1) \bmod 26 = -24 \bmod 26 = 2$
 Step 4: $3 = 3(1) + 0$ $s(4) = 25 - 2(2) \bmod 26 = 21$
 $s(5) = 2 - 21(1) \bmod 26 = -19 \bmod 26 = 7$

Notice that $15(7) = 105 = 1 + 4(26) \equiv 1 \pmod{26}$.

Using the half extended Euclidean algorithm we compute $1/a \bmod b$.

```
inverse:(INT,INT)->INT

```
=====
The Chinese Remainder Algorithm
=====
```

Let m_1, m_2, \dots, m_r be positive integers that are pairwise relatively prime.

Let x_1, x_2, \dots, x_r be integers with $0 \leq x_i < m_i$. Then, there is exactly one x in the interval $0 \leq x < m_1 \dots m_2 \dots m_r$ that satisfies the remainder equations

$$\text{irem}(x, m_i) = x_i, \quad i=1, 2, \dots, r$$

where irem is the positive integer remainder function.

For example, let $x_1 = 4$, $m_1 = 5$, $x_2 = 2$, $m_2 = 3$. We know that

$$\text{irem}(x, m_1) = x_1$$

$$\text{irem}(x, m_2) = x_2$$

where $0 \leq x_1 < m_1$ and $0 \leq x_2 < m_2$.

By the extended Euclidean Algorithm there are integers c and d such that

$$c m_1 + d m_2 = 1$$

In this case we are looking for an integer such that

$$\text{irem}(x, 5) = 4,$$

$$\text{irem}(x, 3) = 2$$

The algorithm we use is to first compute the positive integer remainder of x_1 and m_1 to get a new x_1 :

$$x_1 = \text{positiveRemainder}(x_1, m_1)$$

$$4 = \text{positiveRemainder}(4, 5)$$

Next compute the positive integer remainder of x_2 and m_2 to get a new x_2 :

$$x_2 = \text{positiveRemainder}(x_2, m_2)$$

$$2 = \text{positiveRemainder}(2, 3)$$

Then we compute $x_1 + m_1 \dots \text{positiveRemainder}(((x_2 - x_1) * \text{inverse}(m_1, m_2))), m_2)$

or

$$4 + 5 * \text{positiveRemainder}(((2 - 4) * \text{inverse}(5, 3))), 3)$$

or

$$4 + 5 * \text{positiveRemainder}(-2 * 2), 3)$$

or

$$4 + 5 * 2$$

or

$$14$$

This function has a restricted signature which only allows for computing the chinese remainder of two numbers and two moduli.

$$x_1 := 4$$

$$4$$

  bernoulli : I -> RN
    ++ \spad{bernoulli(n)} returns the nth Bernoulli number.
    ++ this is \spad{B(n,0)}, where \spad{B(n,x)} is the \spad{n}th Bernoulli
    ++ polynomial.
  chineseRemainder: (I,I,I,I) -> I
    ++ \spad{chineseRemainder(x1,m1,x2,m2)} returns w, where w is such that
    ++ \spad{w = x1 mod m1} and \spad{w = x2 mod m2}. Note: \spad{m1} and
    ++ \spad{m2} must be relatively prime.

```

```

divisors : I -> List I
  ++ \spad{divisors(n)} returns a list of the divisors of n.
euler : I -> I
  ++ \spad{euler(n)} returns the \spad{n}th Euler number. This is
  ++ \spad{2^n E(n,1/2)}, where \spad{E(n,x)} is the nth Euler polynomial.
eulerPhi : I -> I
  ++ \spad{eulerPhi(n)} returns the number of integers between 1 and n
  ++ (including 1) which are relatively prime to n. This is the Euler phi
  ++ function \spad{\phi(n)} is also called the totient function.
fibonacci : I -> I
  ++ \spad{fibonacci(n)} returns the nth Fibonacci number. the Fibonacci
  ++ numbers \spad{F[n]} are defined by \spad{F[0] = F[1] = 1} and
  ++ \spad{F[n] = F[n-1] + F[n-2]}.
  ++ The algorithm has running time \spad{O(log(n)^3)}.
  ++ Reference: Knuth, The Art of Computer Programming
  ++ Vol 2, Semi-Numerical Algorithms.
harmonic : I -> RN
  ++ \spad{harmonic(n)} returns the nth harmonic number. This is
  ++ \spad{H[n] = sum(1/k,k=1..n)}.
jacobi : (I,I) -> I
  ++ \spad{jacobi(a,b)} returns the Jacobi symbol \spad{J(a/b)}.
  ++ When b is odd, \spad{J(a/b) = product(L(a/p) for p in factor b )}.
  ++ Note: by convention, 0 is returned if \spad{gcd(a,b) != 1}.
  ++ Iterative \spad{O(log(b)^2)} version coded by Michael Monagan June 1987.
legendre : (I,I) -> I
  ++ \spad{legendre(a,p)} returns the Legendre symbol \spad{L(a/p)}.
  ++ \spad{L(a/p) = (-1)**((p-1)/2) mod p} (p prime), which is 0 if \spad{a}
  ++ is 0, 1 if \spad{a} is a quadratic residue \spad{mod p} and -1 otherwise.
  ++ Note: because the primality test is expensive,
  ++ if it is known that p is prime then use \spad{jacobi(a,p)}.
moebiusMu : I -> I
  ++ \spad{moebiusMu(n)} returns the Moebius function \spad{\mu(n)}.
  ++ \spad{\mu(n)} is either -1,0 or 1 as follows:
  ++ \spad{\mu(n) = 0} if n is divisible by a square > 1,
  ++ \spad{\mu(n) = (-1)^k} if n is square-free and has k distinct
  ++ prime divisors.
numberOfDivisors : I -> I
  ++ \spad{numberOfDivisors(n)} returns the number of integers between 1 and n
  ++ (inclusive) which divide n. The number of divisors of n is often
  ++ denoted by \spad{\tau(n)}.
sumOfDivisors : I -> I
  ++ \spad{sumOfDivisors(n)} returns the sum of the integers between 1 and n
  ++ (inclusive) which divide n. The sum of the divisors of n is often
  ++ denoted by \spad{\sigma(n)}.
sumOfKthPowerDivisors : (I,NNI) -> I
  ++ \spad{sumOfKthPowerDivisors(n,k)} returns the sum of the \spad{k}th

```

```

++ powers of the integers between 1 and n (inclusive) which divide n.
++ the sum of the \spad{k}th powers of the divisors of n is often denoted
++ by \spad{sigma_k(n)}.

++ References: Davenport's paper in ISSAC 1992
++ AXIOM Technical Report ATR/6
++ Description:
++ The \spadtype{IntegerPrimesPackage} implements a modification of
++ Rabin's probabilistic
++ primality test and the utility functions \spadfun{nextPrime},
++ \spadfun{prevPrime} and \spadfun{primes}.
IntegerPrimesPackage(I:IntegerNumberSystem): with
prime?: I -> Boolean
++ \spad{prime?(n)} returns true if n is prime and false if not.
++ The algorithm used is Rabin's probabilistic primality test

```

```

++ (reference: Knuth Volume 2 Semi Numerical Algorithms).
++ If \spad{prime? n} returns false, n is proven composite.
++ If \spad{prime? n} returns true, prime? may be in error
++ however, the probability of error is very low.
++ and is zero below  $25 \cdot 10^9$  (due to a result of Pomerance et al),
++ below  $10^{12}$  and  $10^{13}$  due to results of Pinch,
++ and below 341550071728321 due to a result of Jaeschke.
++ Specifically, this implementation does at least 10 pseudo prime
++ tests and so the probability of error is  $\text{\spad{< }4^{(-10)}}$ .
++ The running time of this method is cubic in the length
++ of the input n, that is  $\text{\spad{O( (log n)^3 )}}$ , for  $n < 10^{20}$ .
++ beyond that, the algorithm is quartic,  $\text{\spad{O( (log n)^4 )}}$ .
++ Two improvements due to Davenport have been incorporated
++ which catches some trivial strong pseudo-primes, such as
++ [Jaeschke, 1991]  $1377161253229053 \cdot 413148375987157$ , which
++ the original algorithm regards as prime
nextPrime: I -> I
  ++ \spad{nextPrime(n)} returns the smallest prime strictly larger than n
prevPrime: I -> I
  ++ \spad{prevPrime(n)} returns the largest prime strictly smaller than n
primes: (I,I) -> List I
  ++ \spad{primes(a,b)} returns a list of all primes p with
  ++ \spad{a <= p <= b}
== add

```

10.54.1 smallPrimes

This is a table of all of the primes in [2..10000]. It is used by the prime? function to check for primality. It is used by the primes function to generate arrays of primes in a given range. Changing the range included in this table implies changing the value of the nextSmallPrime variable. There is a constant in the function squareFree from IntegerFactorizationPackage that is the square of the upper bound of the table range, in this case 10000000.

Exports ==> with

  diagonalProduct: Mat -> R
  ++ diagonalProduct(m) returns the product of the elements on the
```

```

    ++ diagonal of the matrix m
matrixGcd: (Mat,R,NNI) -> R
    ++ matrixGcd(mat,sing,n) is \spad{gcd(sing,g)} where \spad{g} is the
    ++ gcd of the entries of the \spad{n}-by-\spad{n} upper-triangular
    ++ matrix \spad{mat}.
divideIfCan_!: (Matrix R,Matrix R,R,Integer) -> R
    ++ divideIfCan!(matrix,matrixOut,prime,n) attempts to divide the
    ++ entries of \spad{matrix} by \spad{prime} and store the result in
    ++ \spad{matrixOut}. If it is successful, 1 is returned and if not,
    ++ \spad{prime} is returned. Here both \spad{matrix} and
    ++ \spad{matrixOut} are \spad{n}-by-\spad{n} upper triangular matrices.
leastPower: (NNI,NNI) -> NNI
    ++ leastPower(p,n) returns e, where e is the smallest integer
    ++ such that \spad{p **e} >= n}
idealiser: (Mat,Mat) -> Mat
    ++ idealiser(m1,m2) computes the order of an ideal defined by m1 and m2
idealiser: (Mat,Mat,R) -> Mat
    ++ idealiser(m1,m2,d) computes the order of an ideal defined by m1 and m2
    ++ where d is the known part of the denominator
idealiserMatrix: (Mat, Mat) -> Mat
    ++ idealiserMatrix(m1, m2) returns the matrix representing the linear
    ++ conditions on the Ring associated with an ideal defined by m1 and m2.
moduleSum: (Ans,Ans) -> Ans
    ++ moduleSum(m1,m2) returns the sum of two modules in the framed
    ++ algebra \spad{F}. Each module \spad{mi} is represented as follows:
    ++ F is a framed algebra with R-module basis \spad{w1,w2,...,wn} and
    ++ \spad{mi} is a record \spad{[basis,basisDen,basisInv]}. If
    ++ \spad{basis} is the matrix \spad{(aij, i = 1..n, j = 1..n)}, then
    ++ a basis \spad{v1,...,vn} for \spad{mi} is given by
    ++ \spad{vi} = (1/basisDen) * sum(aij * wj, j = 1..n)}, i.e. the
    ++ \spad{i}-th row of 'basis' contains the coordinates of the
    ++ \spad{i}-th basis vector. Similarly, the \spad{i}-th row of the
    ++ matrix \spad{basisInv} contains the coordinates of \spad{wi} with
    ++ respect to the basis \spad{v1,...,vn}: if \spad{basisInv} is the
    ++ matrix \spad{(bij, i = 1..n, j = 1..n)}, then
    ++ \spad{wi} = sum(bij * vj, j = 1..n)}.

rur: (TS,B) -> List TS
++ \spad{rur(ts,univ?)} returns a rational univariate representation
++ of \spad{ts}. This assumes that the lowest polynomial in \spad{ts}
++ is a variable \spad{v} which does not occur in the other polynomials
++ of \spad{ts}. This variable will be used to define the simple
++ algebraic extension over which these other polynomials will be
++ rewritten as univariate polynomials with degree one.
++ If \spad{univ?} is \spad{true} then these polynomials will have
++ a constant initial.
checkRur: (TS, List TS) -> Boolean
++ \spad{checkRur(ts, lus)} returns \spad{true} if \spad{lus}
++ is a rational univariate representation of \spad{ts}.

=====
LazardSetSolvingPackage examples
=====
```

The LazardSetSolvingPackage package constructor solves polynomial systems by means of Lazard triangular sets. However one condition is relaxed: Regular triangular sets whose saturated ideals have positive dimension are not necessarily normalized.

The decompositions are computed in two steps. First the algorithm of Moreno Maza (implemented in the RegularTriangularSet domain constructor) is called. Then the resulting decompositions are converted into lists of square-free regular triangular sets and the redundant components are removed. Moreover, zero-dimensional regular triangular sets are normalized.

Note that the way of understanding triangular decompositions is detailed in the example of the RegularTriangularSet constructor.

The LazardSetSolvingPackage constructor takes six arguments. The first one, R, is the coefficient ring of the polynomials; it must belong to the category GcdDomain. The second one, E, is the exponent monoid of the polynomials; it must belong to the category OrderedAbelianMonoidSup. the third one, V, is the ordered set of variables; it must belong to the category OrderedSet. The fourth one is the polynomial ring; it must belong to the category RecursivePolynomialCategory(R,E,V). The fifth one is a domain of the category RegularTriangularSetCategory(R,E,V,P) and the last one is a domain of the category SquareFreeRegularTriangularSetCategory(R,E,V,P). The abbreviation for LazardSetSolvingPackage is LAZM3PK.

For the purpose of solving zero-dimensional algebraic systems, see also LexTriangularPackage and ZeroDimensionalSolvePackage. These packages are easier to call than LAZM3PK. Moreover, the ZeroDimensionalSolvePackage package provides operations to compute either the complex roots or the real roots.

We illustrate now the use of the LazardSetSolvingPackage package constructor with two examples (Butcher and Vermeer).

Define the coefficient ring.

```
R := Integer
      Integer
```

Define the list of variables,

```
ls : List Symbol := [b1,x,y,z,t,v,u,w]
    [b1,x,y,z,t,v,u,w]
```

and make it an ordered set:

```
V := OVAR(ls)
    OrderedVariableList [b1,x,y,z,t,v,u,w]
```

then define the exponent monoid.

```
E := IndexedExponents V
```

Define the polynomial ring.

```
P := NSMP(R, V)
```

Let the variables be polynomial.

```
b1: P := 'b1
```

```
x: P := 'x
```

```
y: P := 'y
```

```
z: P := 'z
```

```
t: P := 't
```

```
u: P := 'u
```

```
v: P := 'v
```

```
w: P := 'w
```

Now call the `{\tt RegularTriangularSet}` domain constructor.

```
T := REGSET(R,E,V,P)
```

Define a polynomial system (the Butcher example).

```
p0 := b1 + y + z - t - w
```

```
p1 := 2*z*u + 2*y*v + 2*t*w - 2*w**2 - w - 1
```

```

p2 := 3*z*u**2 + 3*y*v**2 - 3*t*w**2 + 3*w**3 + 3*w**2 - t + 4*w
p3 := 6*x*z*v - 6*t*w**2 + 6*w**3 - 3*t*w + 6*w**2 - t + 4*w
p4 := 4*z*u**3+ 4*y*v**3+ 4*t*w**3- 4*w**4 - 6*w**3+ 4*t*w- 10*w**2- w- 1
p5 := 8*x*z*u*v +8*t*w**3 -8*w**4 +4*t*w**2 -12*w**3 +4*t*w -14*w**2 -3*w -1
p6 := 12*x*z*v**2+12*t*w**3 -12*w**4 +12*t*w**2 -18*w**3 +8*t*w -14*w**2 -w -1
p7 := -24*t*w**3 + 24*w**4 - 24*t*w**2 + 36*w**3 - 8*t*w + 26*w**2 + 7*w + 1

lp := [p0, p1, p2, p3, p4, p5, p6, p7]
[b1 + y + z - t - w, 2v y + 2u z + 2w t - 2w - w - 1,
 2      2      2      3      2
3v y + 3u z + (- 3w - 1)t + 3w + 3w + 4w,
 2      3      2
6v z x + (- 6w - 3w - 1)t + 6w + 6w + 4w,
 3      3      3      4      3      2
4v y + 4u z + (4w + 4w)t - 4w - 6w - 10w - w - 1,
 3      2      4      3      2
8u v z x + (8w + 4w + 4w)t - 8w - 12w - 14w - 3w - 1,
 2      3      2      4      3      2
12v z x + (12w + 12w + 8w)t - 12w - 18w - 14w - w - 1,
 3      2      4      3      2
(- 24w - 24w - 8w)t + 24w + 36w + 26w + 7w + 1]

```

First of all, let us solve this system in the sense of Lazard by means of the REGSET constructor:

```

lts := zeroSetSplit(lp,false)$T
[{w + 1,u,v,t + 1,b1 + y + z + 2}, {w + 1,v,t + 1,z,b1 + y + 2},
 {w + 1,t + 1,z,y,b1 + 2}, {w + 1,v - u,t + 1,y + z,x,b1 + 2},
 {w + 1,u,t + 1,y,x,b1 + z + 2},

 5      4      3      2
{144w + 216w + 96w + 6w - 11w - 1,
 2      5      4      3      2
(12w + 9w + 1)u - 72w - 108w - 42w - 9w - 3w,
 2      4      3      2
(12w + 9w + 1)v + 36w + 54w + 18w ,
 3      2      4      3      2
(24w + 24w + 8w)t - 24w - 36w - 26w - 7w - 1,

 2      2      4      3      2
(12u v - 12u )z + (12w v + 12w + 4)t + (3w - 5)v + 36w + 42w + 6w

```

```

+
- 16w
,
2
2v y + 2u z + 2w t - 2w - w - 1,
2      3      2
6v z x + (- 6w - 3w - 1)t + 6w + 6w + 4w, b1 + y + z - t - w}
]

```

We can get the dimensions of each component of a decomposition as follows.

```

[coHeight(ts) for ts in lts]
[3,3,3,2,2,0]

```

The first five sets have a simple shape. However, the last one, which has dimension zero, can be simplified by using Lazard triangular sets.

Thus we call the SquareFreeRegularTriangularSet domain constructor,

```
ST := SREGSET(R,E,V,P)
```

and set the LAZM3PK package constructor to our situation.

```
pack := LAZM3PK(R,E,V,P,T,ST)
```

We are ready to solve the system by means of Lazard triangular sets:

```

zeroSetSplit(lp,false)$pack
[{w + 1,t + 1,z,y,b1 + 2}, {w + 1,v,t + 1,z,b1 + y + 2},
 {w + 1,u,v,t + 1,b1 + y + z + 2}, {w + 1,v - u,t + 1,y + z,x,b1 + 2},
 {w + 1,u,t + 1,y,x,b1 + z + 2},

5      4      3      2      4      3      2
{144w + 216w + 96w + 6w - 11w - 1, u - 24w - 36w - 14w + w + 1,

4      3      2      4      3      2
3v - 48w - 60w - 10w + 8w + 2, t - 24w - 36w - 14w - w + 1,

4      3      2
486z - 2772w - 4662w - 2055w + 30w + 127,

4      3      2
2916y - 22752w - 30312w - 8220w + 2064w + 1561,

4      3      2
356x - 3696w - 4536w - 968w + 822w + 371,

4      3      2
2916b1 - 30600w - 46692w - 20274w - 8076w + 593}
]

```

We see the sixth triangular set is {\em nicer} now: each one of its polynomials has a constant initial.

We follow with the Vermeer example. The ordering is the usual one for this system.

Define the polynomial system.

```
f0 := (w - v) ** 2 + (u - t) ** 2 - 1
```

$$t^2 - 2ut + v^2 - 2wv + u^2 + w^2 - 1$$

```
f1 := t ** 2 - v ** 3
```

$$t^2 - v^3$$

```
f2 := 2 * t * (w - v) + 3 * v ** 2 * (u - t)
```

$$(-3v^2 - 2v + 2w)t + 3uv^2$$

```
f3 := (3 * z * v ** 2 - 1) * (2 * z * t - 1)
```

$$6v^2tz + (-2t - 3v)z + 1$$

```
lf := [f0, f1, f2, f3]
```

$$[t^2 - 2ut + v^2 - 2wv + u^2 + w^2 - 1, t^2 - v^3, (-3v^2 - 2v + 2w)t + 3uv^2, 6v^2tz + (-2t - 3v)z + 1]$$

First of all, let us solve this system in the sense of Kalkbrener by means of the REGSET constructor:

```
zeroSetSplit(lf,true)$T
```

$$\left[\begin{array}{l} \{ \\ \quad 729u^6 + (-1458w^3 + 729w^2 - 4158w - 1685)u^4 \end{array} \right.$$

$$\begin{aligned}
& + \\
& \quad \begin{matrix} 6 & 5 & 4 & 3 & 2 & & 2 & 8 \\ (729w^6 - 1458w^5 - 2619w^4 - 4892w^3 - 297w^2 + 5814w + 427)u^2 + 729w^8 \end{matrix} \\
& + \\
& \quad \begin{matrix} 7 & 6 & 5 & 4 & 3 & 2 \\ 216w^7 - 2900w^6 - 2376w^5 + 3870w^4 + 4072w^3 - 1188w^2 - 1656w + 529 \end{matrix} \\
& , \\
& \quad \begin{matrix} 4 & 3 & 2 & & 2 & 6 & 5 \\ 2187u^4 + (-4374w^3 - 972w^2 - 12474w - 2868)u^2 + 2187w^6 - 1944w^5 \end{matrix} \\
& + \\
& \quad \begin{matrix} 4 & 3 & 2 \\ -10125w^4 - 4800w^3 + 2501w^2 + 4968w - 1587 \end{matrix} \\
& * \\
& \quad v \\
& + \\
& \quad \begin{matrix} 3 & 2 & 2 & 6 & 5 & 4 & 3 & 2 \\ (1944w^3 - 108w^2)u^2 + 972w^6 + 3024w^5 - 1080w^4 + 496w^3 + 1116w^2 \end{matrix} \\
& , \\
& \quad \begin{matrix} 2 & 2 & 2 & 2 & 2 \\ (3v^2 + 2v - 2w)t^2 - 3u^2v, ((4v - 4w)t^2 - 6uv^2)z^2 + (2t^2 + 3v^2)z - 1 \end{matrix} \\
&]
\end{aligned}$$

We have obtained one regular chain (i.e. regular triangular set) with dimension 1. This set is in fact a characterist set of the (radical of) the ideal generated by the input system lf. Thus we have only the generic points of the variety associated with lf (for the elimination ordering given by ls).

So let us get now a full description of this variety.

Hence, we solve this system in the sense of Lazard by means of the REGSET constructor:

$$\begin{aligned}
& \text{zeroSetSplit(lf,false)}\$T \\
& [\\
& \quad \{ \\
& \quad \quad \begin{matrix} 6 & 3 & 2 & 4 \\ 729u^6 + (-1458w^3 + 729w^2 - 4158w - 1685)u^4 \end{matrix} \\
& \quad + \\
& \quad \quad \begin{matrix} 6 & 5 & 4 & 3 & 2 & 2 & 8 \\ (729w^6 - 1458w^5 - 2619w^4 - 4892w^3 - 297w^2 + 5814w + 427)u^2 + 729w^8 \end{matrix} \\
& \quad + \\
& \quad \quad \begin{matrix} 7 & 6 & 5 & 4 & 3 & 2 \\ 216w^7 - 2900w^6 - 2376w^5 + 3870w^4 + 4072w^3 - 1188w^2 - 1656w + 529 \end{matrix} \\
& \quad , \\
& \quad \} \\
&]
\end{aligned}$$

$$\begin{aligned}
& 2187u^4 + (-4374w^3 - 972w^2 - 12474w - 2868)u^2 + 2187w^6 - 1944w^5 \\
& + (-10125w^4 - 4800w^3 + 2501w^2 + 4968w - 1587) \\
& * v \\
& + (1944w^3 - 108w^2)u^2 + 972w^6 + 3024w^5 - 1080w^4 + 496w^3 + 1116w^2 \\
& , \\
& (3v^2 + 2v - 2w)t^2 - 3uv^2, ((4v - 4w)t^2 - 6uv^2)z^2 + (2t + 3v)z - 1\} \\
& , \\
& \{27w^4 + 4w^3 - 54w^2 - 36w + 23, u, (12w + 2)v^2 - 9w^2 - 2w + 9, \\
& 6t^2 - 2v - 3w^2 + 2w + 3, 2tz - 1\} \\
& , \\
& \{59049w^6 + 91854w^5 - 45198w^4 + 145152w^3 + 63549w^2 + 60922w + 21420, \\
& 31484448266904w^5 - 18316865522574w^4 + 23676995746098w^3 \\
& + 6657857188965w^2 + 8904703998546w + 3890631403260 \\
& * u^2 \\
& + 94262810316408w^5 - 82887296576616w^4 + 89801831438784w^3 \\
& + 28141734167208w^2 + 38070359425432w + 16003865949120 \\
& , \\
& (243w^2 + 36w + 85)v^2 + (-81u^2 - 162w^3 + 36w^2 + 154w + 72)v^3 - 72w^3 + 4w^2, \\
& (3v^2 + 2v - 2w)t^2 - 3uv^2, ((4v - 4w)t^2 - 6uv^2)z^2 + (2t + 3v)z - 1\} \\
& ,
\end{aligned}$$

$$\begin{aligned} & \{ 27w^4 + 4w^3 - 54w^2 - 36w + 23, u, (12w + 2)v - 9w^2 - 2w + 9, \\ & 6t^2 - 2v - 3w^2 + 2w + 3, 3vz - 1 \} \\ &] \end{aligned}$$

We retrieve our regular chain of dimension 1 and we get three regular chains of dimension 0 corresponding to the degenerated cases. We want now to simplify these zero-dimensional regular chains by using Lazard triangular sets. Moreover, this will allow us to prove that the above decomposition has no redundant component.

Generally, decompositions computed by the REGSET constructor do not have redundant components. However, to be sure that no redundant component occurs one needs to use the SREGSET or LAZM3PK constructors.

So let us solve the input system in the sense of Lazard by means of the LAZM3PK constructor:

```
zeroSetSplit(lf,false)$pack
[

]
```

Due to square-free factorization, we obtained now four zero-dimensional regular chains. Moreover, each of them is normalized (the initials are constant). Note that these zero-dimensional components may be investigated further with the `ZeroDimensionalSolvePackage` package constructor.

++ Keywords:
++ Description:
++ A package for solving polynomial systems by means of Lazard triangular
++ sets [1].
++ This package provides two operations. One for solving in the sense
++ of the regular zeros, and the other for solving in the sense of
++ the Zariski closure. Both produce square-free regular sets.
++ Moreover, the decompositions do not contain any redundant component.
++ However, only zero-dimensional regular sets are normalized, since
++ normalization may be time consuming in positive dimension.
++ The decomposition process is that of [2].\newline

LexTriangularPackage examples
=====
```

The LexTriangularPackage package constructor provides an implementation of the lexTriangular algorithm (D. Lazard "Solving Zero-dimensional Algebraic Systems", J. of Symbol. Comput., 1992). This algorithm decomposes a zero-dimensional variety into zero-sets of regular triangular sets. Thus the input system must have a finite number of complex solutions. Moreover, this system needs to be a lexicographical Groebner basis.

This package takes two arguments: the coefficient-ring R of the polynomials, which must be a GcdDomain and their set of variables given by ls a List Symbol. The type of the input polynomials must be NewSparseMultivariatePolynomial(R,V) where V is OrderedVariableList(ls). The abbreviation for LexTriangularPackage is LEXTRIPK. The main operations are lexTriangular and squareFreeLexTriangular. The later provide decompositions by means of square-free regular triangular sets, built with the SquareFreeRegularTriangularSet constructor, whereas the former uses the RegularTriangularSet constructor. Note that these constructors also implement another algorithm for solving algebraic systems by means of regular triangular sets; in that case no computations of Groebner bases are needed and the input system may have any dimension (i.e. it may have an infinite number of solutions).

The implementation of the lexTriangular algorithm provided in the LexTriangularPackage constructor differs from that reported in "Computations of gcd over algebraic towers of simple extensions" by M. Moreno Maza and R. Rioboo (in proceedings of AAECC11, Paris, 1995). Indeed, the squareFreeLexTriangular operation removes all multiplicities of the solutions (i.e. the computed solutions are pairwise different) and the lexTriangular operation may keep some multiplicities; this later operation runs generally faster than the former.

The interest of the lexTriangular algorithm is due to the following experimental remark. For some examples, a triangular decomposition of a zero-dimensional variety can be computed faster via a lexicographical Groebner basis computation than by using a direct method (like that of SquareFreeRegularTriangularSet and RegularTriangularSet). This happens typically when the total degree of the system relies essentially on its smallest variable (like in the Katsura systems). When this is not the case, the direct method may give better timings (like in the Rose system).

Of course, the direct method can also be applied to a lexicographical Groebner basis. However, the `lexTriangular` algorithm takes advantage of the structure of this basis and avoids many unnecessary computations which are performed by the direct method.

For this purpose of solving algebraic systems with a finite number of solutions, see also the `ZeroDimensionalSolvePackage`. It allows to use both strategies (the `lexTriangular` algorithm and the direct method) for computing either the complex or real roots of a system.

Note that the way of understanding triangular decompositions is detailed in the example of the `RegularTriangularSet` constructor.

Since the `LexTriangularPackage` package constructor is limited to zero-dimensional systems, it provides a `zeroDimensional?` operation to check whether this requirement holds. There is also a `groebner` operation to compute the lexicographical Groebner basis of a set of polynomials with type `NewSparseMultivariatePolynomial(R,V)`. The elimination ordering is that given by `ls` (the greatest variable being the first element of `ls`). This basis is computed by the FLGM algorithm (Faugere et al. "Efficient Computation of Zero-Dimensional Groebner Bases by Change of Ordering", J. of Symbol. Comput., 1993) implemented in the `LinGroebnerPackage` package constructor.

Once a lexicographical Groebner basis is computed, then one can call the operations `lexTriangular` and `squareFreeLexTriangular`. Note that these operations admit an optional argument to produce normalized triangular sets. There is also a `zeroSetSplit` operation which does all the job from the input system; an error is produced if this system is not zero-dimensional.

Let us illustrate the facilities of the `LexTriangularPackage` constructor by a famous example, the cyclic-6 root system.

Define the coefficient ring.

```
R := Integer
Integer
Type: Domain
```

Define the list of variables,

```
ls : List Symbol := [a,b,c,d,e,f]
[a,b,c,d,e,f]
Type: List Symbol
```

and make it an ordered set.

```
V := OVAR(lis)
  OrderedVariableList [a,b,c,d,e,f]
  Type: Domain
```

Define the polynomial ring.

```
P := NSMP(R, V)
  NewSparseMultivariatePolynomial(Integer, OrderedVariableList [a,b,c,d,e,f])
  Type: Domain
```

Define the polynomials.

```
p1: P := a*b*c*d*e*f - 1
  f e d c b a - 1
  Type: NewSparseMultivariatePolynomial(Integer,
  OrderedVariableList [a,b,c,d,e,f])
```

```
p2: P := a*b*c*d*e + a*b*c*d*f + a*b*c*e*f + a*b*d*e*f + a*c*d*e*f + b*c*d*e*f
  (((e + f)d + f e)c + f e d)b + f e d c)a + f e d c b
  Type: NewSparseMultivariatePolynomial(Integer,
  OrderedVariableList [a,b,c,d,e,f])
```

```
p3: P := a*b*c*d + a*b*c*f + a*b*e*f + a*d*e*f + b*c*d*e + c*d*e*f
  (((d + f)c + f e)b + f e d)a + e d c b + f e d c
  Type: NewSparseMultivariatePolynomial(Integer,
  OrderedVariableList [a,b,c,d,e,f])
```

```
p4: P := a*b*c + a*b*f + a*e*f + b*c*d + c*d*e + d*e*f
  ((c + f)b + f e)a + d c b + e d c + f e d
  Type: NewSparseMultivariatePolynomial(Integer,
  OrderedVariableList [a,b,c,d,e,f])
```

```
p5: P := a*b + a*f + b*c + c*d + d*e + e*f
  (b + f)a + c b + d c + e d + f e
  Type: NewSparseMultivariatePolynomial(Integer,
  OrderedVariableList [a,b,c,d,e,f])
```

```
p6: P := a + b + c + d + e + f
  a + b + c + d + e + f
  Type: NewSparseMultivariatePolynomial(Integer,
  OrderedVariableList [a,b,c,d,e,f])
```

```
lp := [p1, p2, p3, p4, p5, p6]
  [f e d c b a - 1, (((e + f)d + f e)c + f e d)b + f e d c)a + f e d c b,
```

```

(((d + f)c + f e)b + f e d)a + e d c b + f e d c,
((c + f)b + f e)a + d c b + e d c + f e d,
(b + f)a + c b + d c + e d + f e, a + b + c + d + e + f]
Type: List NewSparseMultivariatePolynomial(Integer,
                                             OrderedVariableList [a,b,c,d,e,f])

```

Now call LEXTRIPK.

```

lextripack := LEXTRIPK(R,ls)
LexTriangularPackage(Integer,[a,b,c,d,e,f])
Type: Domain

```

Compute the lexicographical Groebner basis of the system. This may take between 5 minutes and one hour, depending on your machine.

```

lg := groebner(lp)$lextripack
[a + b + c + d + e + f,

```

Note that the first set of the decomposition is normalized (all initials are integer numbers) but not the second one (normalized triangular sets are defined in the description of the `NormalizedTriangularSetCategory` constructor).

So apply now `lexTriangular` to produce normalized triangular sets.

```

```

[ [init(p) for p in (ts :: List(P))] for ts in lts]
[[1,3,1,3,1,1], [1,1,1,1,1,1], [1,1,1,1,1,1], [1,1,1,1,1,1],
[1387545279120,1387545279120,1387545279120,1387545279120,1387545279120,1],
[1,1,1,1,1,1]]
Type: List List NewSparseMultivariatePolynomial(Integer,
OrderedVariableList [a,b,c,d,e,f])

```

Note that each triangular set in `lts` is a lexicographical Groebner basis. Recall that a point belongs to the variety associated with `lp` if and only if it belongs to that associated with one triangular set `ts` in `lts`.

By running the `squareFreeLexTriangular` operation, we retrieve the above decomposition.

```
squareFreeLexTriangular(lg,true)$lextripack

```

```

{f - 1, e + 4f e + f, d + e + 4f, c - f, b - f, a - f}]
Type: List SquareFreeRegularTriangularSet(Integer,
      IndexedExponents OrderedVariableList [a,b,c,d,e,f],
      OrderedVariableList [a,b,c,d,e,f],
      NewSparseMultivariatePolynomial(Integer,
      OrderedVariableList [a,b,c,d,e,f]))

```

Thus the solutions given by `lts` are pairwise different.

We count them as follows.

```

reduce(+,[degree(ts) for ts in lts])
156
Type: PositiveInteger

```

We can investigate the triangular decomposition `lts` by using the `ZeroDimensionalSolvePackage`.

This requires to add an extra variable (smaller than the others) as follows.

```

ls2 : List Symbol := concat(ls,new())$Symbol)
[a,b,c,d,e,f,%A]
Type: List Symbol

```

Then we call the package.

```

zdpack := ZDSOLVE(R,ls,ls2)
(20) ZeroDimensionalSolvePackage(Integer,[a,b,c,d,e,f],[a,b,c,d,e,f,%A])
Type: Domain

```

We compute a univariate representation of the variety associated with the input system as follows.

```

concat [univariateSolve(ts)$zdpack for ts in lts]

Type: List Record(complexRoots: SparseUnivariatePolynomial Integer,
                  coordinates: List Polynomial Integer)

```

Since the `univariateSolve` operation may split a regular set, it returns a list. This explains the use of `concat`.

Look at the last item of the result. It consists of two parts. For

any complex root ? of the univariate polynomial in the first part, we get a tuple of univariate polynomials (in a, ..., f respectively) by replacing %A by ? in the second part. Each of these tuples t describes a point of the variety associated with lp by equaling to zero the polynomials in t.

Note that the way of reading these univariate representations is explained also in the example illustrating the ZeroDimensionalSolvePackage constructor.

Now, we compute the points of the variety with real coordinates.

```
concat [realSolve(ts)$zdpack for ts in lts]

Type: List List RealClosure Fraction Integer

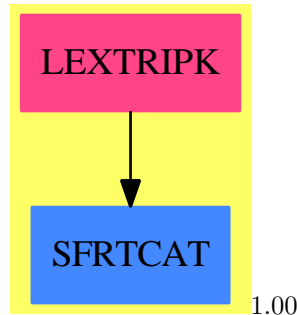

```

We obtain 24 points given by lists of elements in the RealClosure of Fraction of R. In each list, the first value corresponds to the indeterminate f, the second to e and so on.

++ Description:
++ A package for solving polynomial systems with finitely many solutions.
++ The decompositions are given by means of regular triangular sets.
++ The computations use lexicographical Groebner bases.
++ The main operations are \axiomOpFrom{lexTriangular}{LexTriangularPackage}
++ and \axiomOpFrom{squareFreeLexTriangular}{LexTriangularPackage}.
++ The second one provide decompositions by means of square-free regular triangul
++ Both are based on the {\em lexTriangular} method described in [1].
++ They differ from the algorithm described in [2] by the fact that
++ multiciplities of the roots are not kept.
++ With the \axiomOpFrom{squareFreeLexTriangular}{LexTriangularPackage} operation
++ all multiciplities are removed. With the other operation some multiciplities m
++ Both operations admit an optional argument to produce normalized triangular se

13.27 package LIST2 ListFunctions2

13.28 ListFunctions2

Exports:

map reduce scan

```

<package LIST2 ListFunctions2>≡
)abbrev package LIST2 ListFunctions2
++ Author:
++ Date Created:
++ Change History:
++ Basic Operations: map, reduce, scan
++ Related Constructors: List
++ Also See: ListFunctions3
++ AMS Classification:
++ Keywords: list, aggregate, map, reduce
++ Description:
++ \spadtype{ListFunctions2} implements utility functions that
++ operate on two kinds of lists, each with a possibly different
++ type of element.
ListFunctions2(A:Type, B:Type): public == private where
  LA      ==> List A
  LB      ==> List B
  O2      ==> FiniteLinearAggregateFunctions2(A, LA, B, LB)

public ==> with
  scan: ((A, B) -> B, LA, B) -> LB
    ++ scan(fn,u,ident) successively uses the binary function
    ++ \spad{fn} to reduce more and more of list \spad{u}.
    ++ \spad{ident} is returned if the \spad{u} is empty.
    ++ The result is a list of the reductions at each step. See
    ++ \spadfun{reduce} for more information. Examples:
    ++ \spad{scan(fn,[1,2],0) = [fn(2,fn(1,0)),fn(1,0)]} and
    ++ \spad{scan(*,[2,3],1) = [2 * 1, 3 * (2 * 1)]}.
  
```

```

reduce: ((A, B) -> B, LA, B) -> B
++ reduce(fn,u,ident) successively uses the binary function
++ \spad{fn} on the elements of list \spad{u} and the result
++ of previous applications. \spad{ident} is returned if the
++ \spad{u} is empty. Note the order of application in
++ the following examples:
++ \spad{reduce(fn,[1,2,3],0) = fn(3,fn(2,fn(1,0)))} and
++ \spad{reduce(*,[2,3],1) = 3 * (2 * 1)}.
map:      (A -> B, LA) -> LB
++ map(fn,u) applies \spad{fn} to each element of
++ list \spad{u} and returns a new list with the results.
++ For example \spad{map(square,[1,2,3]) = [1,4,9]}.

private ==> add
  map(f, l)      == map(f, l)$02
  scan(f, l, b)  == scan(f, l, b)$02
  reduce(f, l, b) == reduce(f, l, b)$02

(package LIST2MAP ListToMap)≡
)abbrev package LIST2MAP ListToMap
++ Author: Manuel Bronstein
++ Date Created: 22 Mar 1988
++ Change History:
++   11 Oct 1989   MB   ?
++ Basic Operations: match
++ Related Constructors: List
++ Also See:
++ AMS Classification:
++ Keywords: mapping, list
++ Description:
++   \spadtype{ListToMap} allows mappings to be described by a pair of
++   lists of equal lengths. The image of an element \spad{x},
++   which appears in position \spad{n} in the first list, is then
++   the \spad{n}th element of the second list. A default value or
++   default function can be specified to be used when \spad{x}
++   does not appear in the first list. In the absence of defaults,
++   an error will occur in that case.
ListToMap(A:SetCategory, B:Type): Exports == Implementation where
  LA ==> List A
  LB ==> List B
  AB ==> (A -> B)

Exports ==> with
  match: (LA, LB ) -> AB
    ++ match(la, lb) creates a map with no default source or target values
    ++ defined by lists la and lb of equal length.
  
```

```

++ The target of a source value \spad{x} in la is the
++ value y with the same index lb.
++ Error: if la and lb are not of equal length.
++ Note: when this map is applied, an error occurs when
++ applied to a value missing from la.
match: (LA, LB, A) -> B
++ match(la, lb, a) creates a map
++ defined by lists la and lb of equal length, where \spad{a} is used
++ as the default source value if the given one is not in \spad{la}.
++ The target of a source value \spad{x} in la is the
++ value y with the same index lb.
++ Error: if la and lb are not of equal length.
match: (LA, LB, B) -> AB
++ match(la, lb, b) creates a map
++ defined by lists la and lb of equal length, where \spad{b} is used
++ as the default target value if the given function argument is
++ not in \spad{la}.
++ The target of a source value \spad{x} in la is the
++ value y with the same index lb.
++ Error: if la and lb are not of equal length.
match: (LA, LB, A, B) -> B
++ match(la, lb, a, b) creates a map
++ defined by lists la and lb of equal length.
++ and applies this map to a.
++ The target of a source value \spad{x} in la is the
++ value y with the same index lb.
++ Argument b is the default target value if a is not in la.
++ Error: if la and lb are not of equal length.
match: (LA, LB, AB) -> AB
++ match(la, lb, f) creates a map
++ defined by lists la and lb of equal length.
++ The target of a source value \spad{x} in la is the
++ value y with the same index lb.
++ Argument \spad{f} is used as the
++ function to call when the given function argument is not in
++ \spad{la}.
++ The value returned is f applied to that argument.
match: (LA, LB, A, AB) -> B
++ match(la, lb, a, f) creates a map
++ defined by lists la and lb of equal length.
++ and applies this map to a.
++ The target of a source value \spad{x} in la is the
++ value y with the same index lb.
++ Argument \spad{f} is a default function to call if a is not in la.
++ The value returned is then obtained by applying f to argument a.

=====

MakeFunction examples

=====

It is sometimes useful to be able to define a function given by the result of a calculation.

Suppose that you have obtained the following expression after several computations and that you now want to tabulate the numerical values of f for x between -1 and $+1$ with increment 0.1 .

```
expr := (x - exp x + 1)^2 * (sin(x^2) * x + 1)^3
      3   x 2      4      3   x 5      4      3      2 3
      (x (%e ) + (- 2x - 2x )%e + x + 2x + x )sin(x )
+
      2   x 2      3      2   x      4      3      2      2 2
      (3x (%e ) + (- 6x - 6x )%e + 3x + 6x + 3x )sin(x )
+
      x 2      2      x      3      2      2      x 2
      (3x (%e ) + (- 6x - 6x)%e + 3x + 6x + 3x)sin(x ) + (%e )
+
      x      2
      (- 2x - 2)%e + x + 2x + 1
                                         Type: Expression Integer
```

You could, of course, use the function `eval` within a loop and evaluate `expr` twenty-one times, but this would be quite slow. A better way is to create a numerical function f such that $f(x)$ is defined by the expression `expr` above, but without retyping `expr`! The package `MakeFunction` provides the operation function which does exactly this.

Issue this to create the function $f(x)$ given by `expr`.

```
function(expr, f, x)
f
                                         Type: Symbol
```

To tabulate `expr`, we can now quickly evaluate f 21 times.

```
tbl := [f(0.1 * i - 1) for i in 0..20];
                                         Type: List Float
```

Use the list $[x_1, \dots, x_n]$ as the third argument to `function` to create a multivariate function $f(x_1, \dots, x_n)$.

```

e := (x - y + 1)^2 * (x^2 * y + 1)^2
      4 4      5      4      2 3      6      5      4      3      2      2
      x y  + (- 2x  - 2x  + 2x )y  + (x  + 2x  + x  - 4x  - 4x  + 1)y
+
      4      3      2      2
      (2x  + 4x  + 2x  - 2x - 2)y + x  + 2x + 1
                                     Type: Polynomial Integer

```

```

function(e, g, [x, y])
g
                                     Type: Symbol

```

In the case of just two variables, they can be given as arguments without making them into a list.

```

function(e, h, x, y)
h
                                     Type: Symbol

```

Note that the functions created by function are not limited to floating point numbers, but can be applied to any type for which they are defined.

```

m1 := squareMatrix [ [1, 2], [3, 4] ]
      +1  2+
      |    |
      +3  4+
                                     Type: SquareMatrix(2,Integer)

```

```

m2 := squareMatrix [ [1, 0], [-1, 1] ]
      + 1  0+
      |    |
      +- 1  1+
                                     Type: SquareMatrix(2,Integer)

```

```

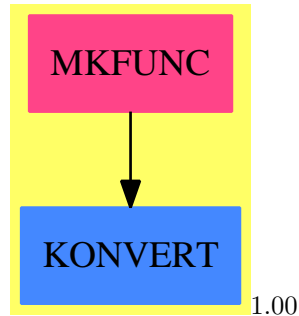

h(m1, m2)
      +- 7836  8960 +
      |          |
      +- 17132 19588+
                                     Type: SquareMatrix(2,Integer)

=====

MappingPackage examples

=====

Function are objects of type Mapping. In this section we demonstrate some library operations from the packages MappingPackage1, MappingPackage2, and MappingPackage3 that manipulate and create functions. Some terminology: a nullary function takes no arguments, a unary function takes one argument, and a binary function takes two arguments.

We begin by creating an example function that raises a rational number to an integer exponent.

```
power(q: FRAC INT, n: INT): FRAC INT == q**n
                                Type: Void
```

```
power(2,3)
8
                                Type: Fraction Integer
```

The twist operation transposes the arguments of a binary function. Here `rewop(a, b)` is `power(b, a)`.

```
rewop := twist power
      theMap(MAPPKG3;twist;MM;5!0)
                                Type: ((Integer,Fraction Integer) -> Fraction Integer)
```

This is 2^3 .

```
rewop(3, 2)
8
                                Type: Fraction Integer
```

Now we define square in terms of power.

```
square: FRAC INT -> FRAC INT
                                Type: Void
```

The `curryRight` operation creates a unary function from a binary one by providing a constant argument on the right.

```
square:= curryRight(power, 2)
      theMap(MAPPKG3;curryRight;MBM;1!0,0)
                                Type: (Fraction Integer -> Fraction Integer)
```

Likewise, the `curryLeft` operation provides a constant argument on the

left.

```
square 4
      16
```

Type: Fraction Integer

The `constantRight` operation creates (in a trivial way) a binary function from a unary one: `constantRight(f)` is the function g such that $g(a,b) = f(a)$.

```
squirrel := constantRight(square)$MAPPKG3(FRAC INT,FRAC INT,FRAC INT)
  theMap(MAPPKG3;constantRight;MM;3!0)
      Type: ((Fraction Integer,Fraction Integer) -> Fraction Integer)
```

Likewise, `constantLeft(f)` is the function g such that $g(a,b) = f(b)$.

```
squirrel(1/2, 1/3)
      1
      -
      4
```

Type: Fraction Integer

The `curry` operation makes a unary function nullary.

```
sixteen := curry(square, 4/1)
  theMap(MAPPKG2;curry;MAM;2!0,0)
      Type: (() -> Fraction Integer)
```

```
sixteen()
      16
```

Type: Fraction Integer

The `*` operation constructs composed functions.

```
square2 := square*square
  theMap(MAPPKG3;*;MMM;6!0,0)
      Type: (Fraction Integer -> Fraction Integer)
```

```
square2 3
      81
```

Type: Fraction Integer

Use the `**` operation to create functions that are n -fold iterations of other functions.

```
sc(x: FRAC INT): FRAC INT == x + 1
```

Type: Void

This is a list of Mapping objects.

```
incfns := [sc**i for i in 0..10]
[theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0)]
Type: List (Fraction Integer -> Fraction Integer)
```

This is a list of applications of those functions.

```
[f 4 for f in incfns]
[4,5,6,7,8,9,10,11,12,13,14]
Type: List Fraction Integer
```

Use the recur operation for recursion:

```
g := recur f means g(n,x) == f(n,f(n-1,...f(1,x))).

times(n:NNI, i:INT):INT == n*i
Type: Void

r := recur(times)
theMap(MAPPKG1;recur;2M;7!0,0)
Type: ((NonNegativeInteger,Integer) -> Integer)
```

This is a factorial function.

```
fact := curryRight(r, 1)
theMap(MAPPKG3;curryRight;MBM;1!0,0)
Type: (NonNegativeInteger -> Integer)

fact 4
24
Type: PositiveInteger
```

Constructed functions can be used within other functions.

```
mto2ton(m, n) ==
raiser := square^n
raiser m
Type: Void
```

This is $3^{(2^3)}$.

```
mto2ton(3, 3)
6561
```

Type: Fraction Integer

Here shiftfib is a unary function that modifies its argument.

```
shiftfib(r: List INT) : INT ==
  t := r.1
  r.1 := r.2
  r.2 := r.2 + t
  t
```

Type: Void

By currying over the argument we get a function with private state.

```
fibinit: List INT := [0, 1]
[0,1]
```

Type: List Integer

```
fibs := curry(shiftfib, fibinit)
theMap(MAPPKG2;curry;MAM;2!0,0)
Type: (() -> Integer)
```

```
[fibs() for i in 0..30]
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987, 1597,
 2584, 4181, 6765, 10946, 17711, 28657, 46368, 75025, 121393, 196418,
 317811, 514229, 832040]
```

Function are objects of type Mapping. In this section we demonstrate some library operations from the packages MappingPackage1, MappingPackage2, and MappingPackage3 that manipulate and create functions. Some terminology: a nullary function takes no arguments, a unary function takes one argument, and a binary function takes two arguments.

We begin by creating an example function that raises a rational number to an integer exponent.

```
power(q: FRAC INT, n: INT): FRAC INT == q**n
                                Type: Void
```

```
power(2,3)
8
                                Type: Fraction Integer
```

The twist operation transposes the arguments of a binary function. Here `rewop(a, b)` is `power(b, a)`.

```
rewop := twist power
theMap(MAPPKG3;twist;MM;5!0)
                                Type: ((Integer,Fraction Integer) -> Fraction Integer)
```

This is 2^3 .

```
rewop(3, 2)
8
                                Type: Fraction Integer
```

Now we define square in terms of power.

```
square: FRAC INT -> FRAC INT
                                Type: Void
```

The `curryRight` operation creates a unary function from a binary one by providing a constant argument on the right.

```
square:= curryRight(power, 2)
theMap(MAPPKG3;curryRight;MBM;1!0,0)
                                Type: (Fraction Integer -> Fraction Integer)
```

Likewise, the `curryLeft` operation provides a constant argument on the

left.

```
square 4
      16
```

Type: Fraction Integer

The constantRight operation creates (in a trivial way) a binary function from a unary one: constantRight(f) is the function g such that $g(a,b) = f(a)$.

```
squirrel := constantRight(square)$MAPPKG3(FRAC INT,FRAC INT,FRAC INT)
  theMap(MAPPKG3;constantRight;MM;3!0)

`<MappingPackage3.help>≡`

```
=====
MappingPackage examples
=====
```

Function are objects of type Mapping. In this section we demonstrate some library operations from the packages MappingPackage1, MappingPackage2, and MappingPackage3 that manipulate and create functions. Some terminology: a nullary function takes no arguments, a unary function takes one argument, and a binary function takes two arguments.

We begin by creating an example function that raises a rational number to an integer exponent.

```
power(q: FRAC INT, n: INT): FRAC INT == q**n
                                Type: Void
```

```
power(2,3)
8
                                Type: Fraction Integer
```

The twist operation transposes the arguments of a binary function. Here `rewop(a, b)` is `power(b, a)`.

```
rewop := twist power
theMap(MAPPKG3;twist;MM;5!0)
                                Type: ((Integer,Fraction Integer) -> Fraction Integer)
```

This is 2^3 .

```
rewop(3, 2)
8
                                Type: Fraction Integer
```

Now we define square in terms of power.

```
square: FRAC INT -> FRAC INT
                                Type: Void
```

The `curryRight` operation creates a unary function from a binary one by providing a constant argument on the right.

```
square:= curryRight(power, 2)
theMap(MAPPKG3;curryRight;MBM;1!0,0)
                                Type: (Fraction Integer -> Fraction Integer)
```

Likewise, the `curryLeft` operation provides a constant argument on the

left.

```
square 4
      16
```

Type: Fraction Integer

The constantRight operation creates (in a trivial way) a binary function from a unary one: constantRight(f) is the function g such that $g(a,b) = f(a)$.

```
squirrel := constantRight(square)$MAPPKG3(FRAC INT,FRAC INT,FRAC INT)
  theMap(MAPPKG3;constantRight;MM;3!0)
      Type: ((Fraction Integer,Fraction Integer) -> Fraction Integer)
```

Likewise, constantLeft(f) is the function g such that $g(a,b) = f(b)$.

```
squirrel(1/2, 1/3)
      1
      -
      4
```

Type: Fraction Integer

The curry operation makes a unary function nullary.

```
sixteen := curry(square, 4/1)
  theMap(MAPPKG2;curry;MAM;2!0,0)
      Type: (() -> Fraction Integer)
```

```
sixteen()
      16
```

Type: Fraction Integer

The * operation constructs composed functions.

```
square2 := square*square
  theMap(MAPPKG3;*;MMM;6!0,0)
      Type: (Fraction Integer -> Fraction Integer)
```

```
square2 3
      81
```

Type: Fraction Integer

Use the ** operation to create functions that are n-fold iterations of other functions.

```
sc(x: FRAC INT): FRAC INT == x + 1
```

Type: Void

This is a list of Mapping objects.

```
incfns := [sc**i for i in 0..10]
[theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0), theMap(MAPPKG1;**;MNniM;6!0,0),
 theMap(MAPPKG1;**;MNniM;6!0,0)]
Type: List (Fraction Integer -> Fraction Integer)
```

This is a list of applications of those functions.

```
[f 4 for f in incfns]
[4,5,6,7,8,9,10,11,12,13,14]
Type: List Fraction Integer
```

Use the recur operation for recursion:

```
g := recur f means g(n,x) == f(n,f(n-1,...f(1,x))).

times(n:NNI, i:INT):INT == n*i
Type: Void

r := recur(times)
theMap(MAPPKG1;recur;2M;7!0,0)
Type: ((NonNegativeInteger,Integer) -> Integer)
```

This is a factorial function.

```
fact := curryRight(r, 1)
theMap(MAPPKG3;curryRight;MBM;1!0,0)
Type: (NonNegativeInteger -> Integer)

fact 4
24
Type: PositiveInteger
```

Constructed functions can be used within other functions.

```
mto2ton(m, n) ==
raiser := square^n
raiser m
Type: Void
```

This is $3^{(2^3)}$.

```

mto2ton(3, 3)
6561

```

Type: Fraction Integer

Here shiftfib is a unary function that modifies its argument.

```

shiftfib(r: List INT) : INT ==
  t := r.1
  r.1 := r.2
  r.2 := r.2 + t
  t

```

Type: Void

By currying over the argument we get a function with private state.

```

fibinit: List INT := [0, 1]
[0,1]

```

Type: List Integer

```

fibs := curry(shiftfib, fibinit)
theMap(MAPPKG2;curry;MAM;2!0,0)
Type: (() -> Integer)

```

```

[fibs() for i in 0..30]
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, 377, 610, 987, 1597,

`<MappingPackage4.help>≡`

```
=====
MappingPackage examples
=====
```

We can construct some simple maps that take a variable x into an equation:

```
p:=(x:EXPR(INT)):EXPR(INT)-->3*x
q:=(x:EXPR(INT)):EXPR(INT)-->2*x+3
```

Now we can do the four arithmetic operations, $+$, $-$, $*$, $/$ on these newly constructed mappings. Since the maps are from the domain Expression Integer to the same domain we can also use symbolic values for the argument. All of the following will return 0, showing that function composition is equivalent to the result of doing the operations individually.

```
(p+q)(4)-(p(4)+q(4))
(p+q)(x)-(p(x)+q(x))
```

```
(p-q)(4)-(p(4)-q(4))
(p-q)(x)-(p(x)-q(x))
```

```
(p*q)(4)-(p(4)*q(4))
(p*q)(x)-(p(x)*q(x))
```

```
(p/q)(4)-(p(4)/q(4))
(p/q)(x)-(p(x)/q(x))
```

We can construct simple maps from Integer to Integer but this limits our ability to do division.

```
r:=(x:INT):INT--> (x*x*x)
s:=(y:INT):INT--> (y*y+3)
```

Again, all of these will return 0:

```
(r+s)(4)-(r(4)+s(4))
(r-s)(4)-(r(4)-s(4))
(r*s)(4)-(r(4)*s(4))
```

If we want to do division with Integer inputs we create the appropriate map:

```
t:=(x:INT):EXPR(INT)--> (x*x*x)
```

```
u:=(y:INT):EXPR(INT)--> (y*y+3)
```

```
(t/u)(4)-(t(4)/u(4))
```

We can even recover the original functions if we make a map that always returns the constant 1:

```
h:=(x:EXPR(INT)):EXPR(INT)-->1
```

```
theMap(Closure)
```

```
      Type: (Expression Integer -> Expression Integer)
```

```
(p/h)(x)
```

```
      3x
```

```
      Type: Expression Integer
```

```
(q/h)(x)
```

```
      2x + 3
```

```
      Type: Expression Integer
```

14.25 package MMLFORM MathMLFormat

Both this code and documentation are still under development and I don't pretend they are anywhere close to perfect or even finished. However the code does work and I hope it might be useful to somebody both for its ability to output MathML from Axiom and as an example of how to write a new output form.

14.25.1 Introduction to Mathematical Markup Language

MathML exists in two forms: presentation and content. At this time (2007-02-11) the package only has a presentation package. A content package is in the works however it is more difficult. Unfortunately Axiom does not make its semantics easily available. The **OutputForm** domain mediates between the individual Axiom domains and the user visible output but **OutputForm** does not provide full semantic information. From my currently incomplete understanding of Axiom it appears that remedying this would entail going back to the individual domains and rewriting a lot of code. However some semantics are conveyed directly by **OutputForm** and other things can be deduced from **OutputForm** or from the original user command.

14.25.2 Displaying MathML

The MathML string produced by ")set output mathml on" can be pasted directly into an appropriate xhtml page and then viewed in Firefox or some other MathML aware browser. The boiler plate code needed for a test page, test-mathml.xml, is:

```
<?xml version="1.0" ?>

<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1 plus MathML 2.0//EN"
    "http://www.w3.org/Math/DTD/mathml2/xhtml-math11-f.dtd" [
<!ENTITY mathml "http://www.w3.org/1998/Math/MathML">
]>

<html xmlns="http://www.w3.org/1999/xhtml"
    xmlns:xlink="http://www.w3.org/1999/xlink" >

    <head>
        <title>MathML Test </title>
    </head>

    <body>

    </body>
```

```
</html>
```

Paste the MathML string into the body element and it should display nicely in Firefox.

14.25.3 Test Cases

Here's a list of test cases that currently format correctly:

1. $(x+y)^2$
2. $\int x^2 x \, dx$
3. $\int x^2 x \, dx$
4. $(5 + \sqrt{63} + \sqrt{847})^{1/3}$
5. $\{1, 2, 3\}$
6. $\{x \bmod 5 \text{ for } x \text{ in primes}(2, 1000)\}$
7. $\text{series}(\sin(a^x), x=0)$
8. $\text{matrix} [[x^i + y^j \text{ for } i \text{ in } 1..10] \text{ for } j \text{ in } 1..10]$
9. $y := \text{operator } 'y \text{ a. } D(y(x, z), [x, x, z, x]) \text{ b. } D(y \ x, x, 2)$
10. $x := \text{series } 'x \text{ a. } \sin(1+x)$
11. $\text{series}(1/\log(y), y=1)$
12. $y:\text{UTS}(\text{FLOAT}, 'z, 0) := \exp(z)$
13. a. $c := \text{continuedFraction}(314159/100000)$ b. $c := \text{continuedFraction}(314159/100000)$

The **TexFormat** domain has the capability to format an object with subscripts, superscripts, presubscripts and presuperscripts however I don't know of any Axiom command that produces such an object. In fact at present I see the case of "SUPERSUB" being used for putting primes in the superscript position to denote ordinary differentiation. I also only see the "SUB" case being used to denote partial derivatives.

14.25.4)set output mathml on

Making mathml appear as output during a normal Axiom session by invoking ")set output mathml on" proved to be a bit tedious and seems to be undocumented. I document my experience here in case it proves useful to somebody else trying to get a new output format from Axiom.

In **MathMLFormat** the functions *coerce(expr : OutputForm) : String* and *display(s : String) : Void* provide the desired mathml output. Note that this package was constructed by close examination of Robert Sutor's **TexFormat** domain and much remains from that source. To have mathml displayed as

output we need to get Axiom to call `display(coerce(expr))` at the appropriate place. Here's what I did to get that to happen. Note that my starting point here was an attempt by Andrey Grozin to do the same. To figure things out I searched through files for "tex" to see what was done for the **TeXFormat** domain, and used `grep` to find which files had mention of **TeXFormat**.

14.25.5 File `src/interp/setvars.boot.pamphlet`

Create an output `mathml` section by analogy to the `tex` section. Remember to add the code chunk "outputmathmlCode" at the end.

`setvars.boot` is a bootstrap file which means that it has to be precompiled into lisp code and then that code has to be inserted back into `setvars.boot`. To do this extract the boot code by running "notangle" on it. I did this from the "tmp" directory. From inside axiom run ")lisp (boottran::boottool "tmp/setvars.boot")" which put "setvars.clisp" into "int/interp/setvars.clisp". Then replace the lisp in "setvars.boot.pamphlet" with that in the newly generated "setvars.clisp".

The relevant code chunks appearing in "setvars.boot.pamphlet" are:

```
outputmathmlCode
setOutputMathml
describeSetOutputMathml
```

and the relevant variables are:

```
setOutputMathml
$mathmlOutputStream
$mathmlOutputFile
$mathmlFormat
describeSetOutputMathml
```

14.25.6 File `setvart.boot.pamphlet`

Create an output `mathml` section in "setvart.boot.pamphlet" again patterned after the `tex` section. I changed the default file extension from ".stex" to ".smml".

To the "sectionoutput" table I added the line

```
mathml                created output in MathML style      Off:CONSOLE
```

Added the code chunk "outputmathml" to the code chunk "output" in "sectionoutput".

Relevant code chunks:

```
outputmathml
```

Relevant variables:

```

setOutputMathml
$mathmlFormat
$mathmlOutputFile

```

Note when copying the tex stuff I changed occurrences of "tex" to "mathml", "Tex" to "Mathml" and "TeX" to "MathML".

14.25.7 File src/algebra/Makefile.pamphlet

The file "src/algebra/tex.spad.pamphlet" contains the domain **TexFormat** (TEX) and the package **TexFormat1** (TEX1). However the sole function of **TexFormat1** is to *coerce* objects from a domain into **OutputForm** and then apply **TexFormat** to them. It is to save programmers the trouble of doing the coercion themselves from inside spad code. It does not appear to be used for the main purpose of delivering Axiom output in TeX format. In order to keep the mathml package as simple as possible, and because I didn't see much use for this, I didn't copy the **TexFormat1** package. So no analog of the TEX1 entries in "Makefile.pamphlet" were needed. One curiosity I don't understand is why TEX1 appears in layer 4 when it seems to depend on TEX which appears in layer 14.

Initially I added "\$OUT/MMLFORM.o" to layer 14 and "mathml.spad.pamphlet" to completed spad files in layer 14. When trying to compile the build failed at MMLFORM. It left "MMLFORM.erlib" in "int/algebra" instead of "MMLFORM.NRLIB" which confused me at first because mathml.spad compiled under a running axiom. By examining the file "obj/tmp/trace" I saw that a new dependency had been introduced, compared to TexFormat, with the function eltName depending on the domain FSAGG in layer 16. So the lines had to be moved from layer 14 to layer 17.

Added appropriate lines to "SPADFILES" and "DOCFILES".

14.25.8 File src/algebra/exposed.lsp.pamphlet

Add the line "(|MathMLFormat| . MMLFORM)"

14.25.9 File src/algebra/Lattice.pamphlet

I don't see that this file is used anywhere but I made the appropriate changes anyway by searching for "TEX" and mimicing everything for MMLFORM.

14.25.10 File src/doc/axiom.bib.pamphlet

Added mathml.spad subsection to "src/doc/axiom.bib.pamphlet".

14.25.11 File interp/i-output.boot.pamphlet

This is where the *coerce* and *display* functions from MathMLFormat actually get called. The following was added:

```
mathmlFormat expr ==
  mml := '(MathMLFormat)
  mmlrep := '(String)
  formatFn := getFunctionFromDomain("coerce",mml,[$OutputForm])
  displayFn := getFunctionFromDomain("display",mml,[mmlrep])
  SPADCALL(SPADCALL(expr,formatFn),displayFn)
  TERPRI $mathmlOutputStream
  FORCE_-OUTPUT $mathmlOutputStream
  NIL
```

Note that compared to the *texFormat* function there are a couple of differences. Since **MathMLFormat** is currently a package rather than a domain there is the "mmlrep" variable whereas in *texFormat* the argument of the "display" function is an instance of the domain. Also the *coerce* function here only has one argument, namely "\$OutputForm".

Also for the function "output(expr,domain)" add lines for mathml, e.g. "if \$mathmlFormat then mathmlFormat expr".

After these changes Axiom compiled with mathml enabled under)set output.

14.25.12 Public Declarations

The declarations

```
E      ==> OutputForm
I      ==> Integer
L      ==> List
S      ==> String
US     ==> UniversalSegment(Integer)
```

provide abbreviations for domains used heavily in the code. The publicly exposed functions are:

coerce: $E \rightarrow S$ This function is the main one for converting an expression in domain OutputForm into a MathML string.

coerceS: $E \rightarrow S$ This function is for use from the command line. It converts an OutputForm expression into a MathML string and does some formatting so that the output is not one long line. If you take the output from this function, stick it in an emacs buffer in nxml-mode and then indent according to mode, you'll get something that's nicer to look at than what comes from *coerce*. Note that *coerceS* returns the same value as *coerce* but invokes a display function as well so that the result will be printed twice in different formats. The need for

this is that the output from `coerce` is automatically formatted with line breaks by Axiom's output routine that are not in the right place.

coerceL: $E \rightarrow S$ Similar to `coerceS` except that the displayed result is the MathML string in one long line. These functions can be used, for instance, to get the MathML for the previous result by typing `coerceL`(

expres: $E \rightarrow S$ Converts **OutputForm** to **String** with the structure preserved with braces. This is useful in developing this package. Actually this is not quite accurate. The function *precondition* is first applied to the **OutputForm** expression before *expres*. Raw **OutputForm** and the nature of the *precondition* function is still obscure to me at the time of this writing (2007-02-14), however I probably need to understand it to make sure I'm not missing any semantics. The `spad` function *precondition* is just a wrapper for the `lisp` function `outputTranSLisp`, which I guess is compiled from `boot`.

display: $S \rightarrow \text{Void}$ This one prints the string returned by `coerce` as one long line, adding "math" tags: `$...$`. Thus the output from this can be stuck directly into an appropriate `html/xhtml` page and will be displayed nicely by a MathML aware browser.

displayF: $S \rightarrow \text{Void}$ This function doesn't exist yet but it would be nice to have a humanly readable formatted output as well. The basics do exist in the `coerceS` function however the formatting still needs some work to be really good.

```
(public declarations)≡
)abbrev domain MMLFORM MathMLFormat
++ Author: Arthur C. Ralfs
++ Date: January 2007
++ This package is based on the TeXFormat domain by Robert S. Sutor
++ without which I wouldn't have known where to start.
++ Basic Operations: coerce, coerceS, coerceL, expres, display
++ Description:
++   \spadtype{MathMLFormat} provides a coercion from \spadtype{OutputForm}
++   to MathML format.
```

```
MathMLFormat(): public == private where
```

```

E      ==> OutputForm
I      ==> Integer
L      ==> List
S      ==> String
US     ==> UniversalSegment(Integer)
```

```
public == SetCategory with
```

```

coerce:   E -> S
++ coerceS(o) changes o in the standard output format to MathML
++ format.
coerceS:  E -> S
++ coerceS(o) changes o in the standard output format to MathML
```

```

    ++ format and displays formatted result.
coerceL:  E -> S
    ++ coerceS(o) changes o in the standard output format to MathML
    ++ format and displays result as one long string.
expres:   E -> S
    ++ converts \spadtype{OutputForm} to \spadtype{String} with the
    ++ structure preserved with braces.  Actually this is not quite
    ++ accurate.  The function \spadfun{precondition} is first
    ++ applied to the
    ++ \spadtype{OutputForm} expression before \spadfun{expres}.
    ++ The raw \spadtype{OutputForm} and
    ++ the nature of the \spadfun{precondition} function is
    ++ still obscure to me
    ++ at the time of this writing (2007-02-14).
display:  S -> Void
    ++ prints the string returned by coerce, adding <math ...> tags.

```

14.25.14 Private Function Declarations

These are the local functions:

addBraces:S -> S

addBrackets:S -> S

atomize:E -> L E

displayElt:S -> Void function for recursively displaying mathml nicely formatted

eltLimit:(S,I,S) -> I demarcates end postion of mathml element with name:S starting at position i:I in mathml string s:S and returns end of end tag as i:I position in mathml string, i.e. find start and end of substring: <name ...>...</name>

eltName:(I,S) -> S find name of mathml element starting at position i:I in string s:S

group:S -> S

formatBinary:(S,L E, I) -> S

formatFunction:(S,L E, I) -> S

formatMatrix:L E -> S

formatNary:(S,L E, I) -> S

formatNaryNoGroup:(S,L E, I) -> S

formatNullary:S -> S

formatPlex:(S,L E, I) -> S

formatSpecial:(S,L E, I) -> S

formatUnary:(S, E, I) -> S

formatMml:(E,I) -> S

newWithNum:I -> \$ this is a relic from tex.spad and is not used here so far. I'll probably remove it.

parenthesize:S -> S

precondition:E -> E this function is applied to the OutputForm expression before doing anything else.

postcondition:S -> S this function is applied after all other OutputForm -> MathML transformations. In the TexFormat domain the ungroup function first peels off the outermost set of braces however I have replaced braces with <mrow>s here and sometimes the outermost set of <mrow>s is necessary to get proper display in Firefox. For instance with getting the correct size of brackets on a matrix the whole expression needs to be enclosed in a mrow element. It also checks for +- and removes the +.

stringify:E -> S

tagEnd:(S,I,S) -> I finds closing ">" of start or end tag for mathML element for formatting MathML string for human readability. No analog in TexFormat.

ungroup:S -> S

```

14.25.15 Public Function Definitions

Note that I use the function `sayTeX$Lisp` much as I would `printf` in a C program. I've noticed in grepping the code that there are other "say" functions, `sayBrightly` and `sayMessage` for instance, but I have no idea what the difference is between them at this point. `sayTeX$Lisp` does the job so for the time being I'll use that until I learn more.

The functions `coerceS` and `coerceL` should probably be changed to display functions, *i.e.* `displayS` and `displayL`, returning `Void`. I really only need the one `coerce` function.

```

⟨public function definitions⟩≡
  -- public function definitions

  coerce(expr : E): S ==
    s : S := postcondition formatMml(precondition expr, minPrec)
    s

  coerceS(expr : E): S ==

Formatting Functions

Still need to format `\zag` in `formatSpecial!`

In `formatPlex` the case `op = "INTSIGN"` is now passed off to `formatIntSign` which is a change from the `TexFormat` domain. This is done here for presentation mark up to replace the ugly bound variable that Axiom delivers. For content mark up this has to be done anyway.

The `formatPlex` function also allows for `op = "INDEFINTEGRAL"`. However I don't know what Axiom command gives rise to this case. The `INTSIGN` case already allows for both definite and indefinite integrals.

In the function `formatSpecial` various cases are handled including `SUB` and `SUPERSUB`. These cases are now caught in `formatMml` and so the code in `formatSpecial` doesn't get executed. The only cases I know of using these are partial derivatives for `SUB` and ordinary derivatives or `SUPERSUB` however in `TexFormat` the capability is there to handle multiscripts, i.e. an object with subscripts, superscripts, pre-subscripts and pre-superscripts but I am so far unaware of any Axiom command that produces such a multiscripted object.

Another question is how to represent derivatives. At present I have differential notation for partials and prime notation for ordinary derivatives, but it would be nice to allow for different derivative notations in different circumstances, maybe some options to `)set output mathml` on.

Ordinary derivatives are formatted in `formatSuperSub` and there are 2 versions, `formatSuperSub` and `formatSuperSub1`, which at this point have to be switched by swapping names.

++ Author: Clifton J. Williamson, P.Gianni
++ Date Created: 13 November 1989
++ Date Last Updated: December 1992
++ Basic Operations:
++ Related Domains: IndexedMatrix(R,minRow,minCol), Matrix(R),
++   RectangularMatrix(n,m,R), SquareMatrix(n,R)
++ Also See:
++ AMS Classifications:
++ Keywords: matrix, canonical forms, linear algebra
++ Examples:
++ References:
++ Description:
++   \spadtype{MatrixLinearAlgebraFunctions} provides functions to compute
++   inverses and canonical forms.
MatrixLinearAlgebraFunctions(R,Row,Col,M):Exports == Implementation where
  R   : CommutativeRing
  Row : FiniteLinearAggregate R
  Col : FiniteLinearAggregate R
  M   : MatrixCategory(R,Row,Col)
  I ==> Integer

Exports ==> with

```

```

determinant: M -> R
  ++ \spad{determinant(m)} returns the determinant of the matrix m.
  ++ an error message is returned if the matrix is not square.
minordet: M -> R
  ++ \spad{minordet(m)} computes the determinant of the matrix m using
  ++ minors. Error: if the matrix is not square.
elRow1!      : (M,I,I)      -> M
  ++ elRow1!(m,i,j) swaps rows i and j of matrix m : elementary operation
  ++ of first kind
elRow2!      : (M,R,I,I)    -> M
  ++ elRow2!(m,a,i,j) adds to row i a*row(m,j) : elementary operation of
  ++ second kind. (i ^=j)
elColumn2!   : (M,R,I,I)    -> M
  ++ elColumn2!(m,a,i,j) adds to column i a*column(m,j) : elementary
  ++ operation of second kind. (i ^=j)

if R has IntegralDomain then
  rank: M -> NonNegativeInteger
    ++ \spad{rank(m)} returns the rank of the matrix m.
  nullity: M -> NonNegativeInteger
    ++ \spad{nullity(m)} returns the nullity of the matrix m. This is
    ++ the dimension of the null space of the matrix m.
  nullSpace: M -> List Col
    ++ \spad{nullSpace(m)} returns a basis for the null space of the
    ++ matrix m.
  fractionFreeGauss! : M -> M
    ++ \spad{fractionFreeGauss(m)} performs the fraction
    ++ free gaussian elimination on the matrix m.
  invertIfCan : M -> Union(M,"failed")
    ++ \spad{invertIfCan(m)} returns the inverse of m over R
  adjoint : M -> Record(adjMat:M, detMat:R)
    ++ \spad{adjoint(m)} returns the adjoint matrix of m (i.e. the matrix
    ++ n such that m*n = determinant(m)*id) and the determinant of m.

if R has EuclideanDomain then
  rowEchelon: M -> M
    ++ \spad{rowEchelon(m)} returns the row echelon form of the matrix m.

  normalizedDivide: (R, R) -> Record(quotient:R, remainder:R)
    ++ normalizedDivide(n,d) returns a normalized quotient and
    ++ remainder such that consistently unique representatives
    ++ for the residue class are chosen, e.g. positive remainders

if R has Field then
  inverse: M -> Union(M,"failed")
    ++ \spad{inverse(m)} returns the inverse of the matrix.

```

```

++ If the matrix is not invertible, "failed" is returned.
++ Error: if the matrix is not square.

```
