=====
Permanent examples
=====
```

The package Permanent provides the function permanent for square matrices. The permanent of a square matrix can be computed in the same way as the determinant by expansion of minors except that for the permanent the sign for each element is 1, rather than being 1 if the row plus column indices is positive and -1 otherwise. This function is much more difficult to compute efficiently than the determinant. An example of the use of permanent is the calculation of the n-th derangement number, defined to be the number of different possibilities for n couples to dance but never with their own spouse.

Consider an n by n matrix with entries 0 on the diagonal and 1 elsewhere. Think of the rows as one-half of each couple (for example, the males) and the columns the other half. The permanent of such a matrix gives the desired derangement number.

```
kn n ==
 r : MATRIX INT := new(n,n,1)
 for i in 1..n repeat
 r.i.i := 0
 r
```

Here are some derangement numbers, which you see grow quite fast.

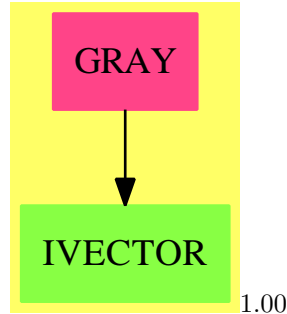

```
permanent(kn(5) :: SQMATRIX(5,INT))

[permanent(kn(n) :: SQMATRIX(n,INT)) for n in 1..13]
```

permanent: SM -> R
++ permanent(x) computes the permanent of a square matrix x.
++ The {\em permanent} is equivalent to
++ the \spadfun{determinant} except that coefficients have
++ no change of sign. This function
++ is much more difficult to compute than the
++ {\em determinant}. The formula used is by H.J. Ryser,
++ improved by [Nijenhuis and Wilf, Ch. 19].
++ Note: permanent(x) choose one of three algorithms, depending
++ on the underlying ring R and on n, the number of rows (and
++ columns) of x:\begin{items}
++ \item 1. if 2 has an inverse in R we can use the algorithm of
++ [Nijenhuis and Wilf, ch.19,p.158]; if 2 has no inverse,
++ some modifications are necessary:
++ \item 2. if {\em n > 6} and R is an integral domain with characteristic
++ different from 2 (the algorithm works if and only 2 is not a
++ zero-divisor of R and {\em characteristic()}$R \neq 2},
++ but how to check that for any given R ?),
++ the local function {\em permanent2} is called;
++ \item 3. else, the local function {\em permanent3} is called
++ (works for all commutative rings R).
++ \end{items}

symmetricGroup: PI -> PERMGRP I
++ symmetricGroup(n) constructs the symmetric group {\em Sn}
++ acting on the integers 1,...,n, generators are the
++ {\em n}-cycle {\em (1,...,n)} and the 2-cycle {\em (1,2)}.
symmetricGroup: L I -> PERMGRP I
++ symmetricGroup(li) constructs the symmetric group acting on
++ the integers in the list {\em li}, generators are the
++ cycle given by {\em li} and the 2-cycle {\em (li.1,li.2)}.
++ Note: duplicates in the list will be removed.
alternatingGroup: PI -> PERMGRP I
++ alternatingGroup(n) constructs the alternating group {\em An}
++ acting on the integers 1,...,n, generators are in general the
++ {\em n-2}-cycle {\em (3,...,n)} and the 3-cycle {\em (1,2,3)}
++ if n is odd and the product of the 2-cycle {\em (1,2)} with
++ {\em n-2}-cycle {\em (3,...,n)} and the 3-cycle {\em (1,2,3)}
++ if n is even.
alternatingGroup: L I -> PERMGRP I
++ alternatingGroup(li) constructs the alternating group acting
++ on the integers in the list {\em li}, generators are in general the
++ {\em n-2}-cycle {\em (li.3,...,li.n)} and the 3-cycle
++ {\em (li.1,li.2,li.3)}, if n is odd and
++ product of the 2-cycle {\em (li.1,li.2)} with
++ {\em n-2}-cycle {\em (li.3,...,li.n)} and the 3-cycle
++ {\em (li.1,li.2,li.3)}, if n is even.
++ Note: duplicates in the list will be removed.
abelianGroup: L PI -> PERMGRP I
++ abelianGroup([n1,...,nk]) constructs the abelian group that
++ is the direct product of cyclic groups with order {\em ni}.
cyclicGroup: PI -> PERMGRP I
++ cyclicGroup(n) constructs the cyclic group of order n acting
++ on the integers 1,...,n.
cyclicGroup: L I -> PERMGRP I
++ cyclicGroup([i1,...,ik]) constructs the cyclic group of
++ order k acting on the integers {\em i1},...,{\em ik}.
++ Note: duplicates in the list will be removed.
dihedralGroup: PI -> PERMGRP I
++ dihedralGroup(n) constructs the dihedral group of order 2n
++ acting on integers 1,...,N.
dihedralGroup: L I -> PERMGRP I

```

```

++ dihedralGroup([i1,...,ik]) constructs the dihedral group of
++ order 2k acting on the integers out of {\em i1},...,{\em ik}.
++ Note: duplicates in the list will be removed.
mathieu11: L I -> PERMGRP I
++ mathieu11(li) constructs the mathieu group acting on the 11
++ integers given in the list {\em li}.
++ Note: duplicates in the list will be removed.
++ error, if {\em li} has less or more than 11 different entries.
mathieu11: () -> PERMGRP I
++ mathieu11 constructs the mathieu group acting on the
++ integers 1,...,11.
mathieu12: L I -> PERMGRP I
++ mathieu12(li) constructs the mathieu group acting on the 12
++ integers given in the list {\em li}.
++ Note: duplicates in the list will be removed
++ Error: if {\em li} has less or more than 12 different entries.
mathieu12: () -> PERMGRP I
++ mathieu12 constructs the mathieu group acting on the
++ integers 1,...,12.
mathieu22: L I -> PERMGRP I
++ mathieu22(li) constructs the mathieu group acting on the 22
++ integers given in the list {\em li}.
++ Note: duplicates in the list will be removed.
++ Error: if {\em li} has less or more than 22 different entries.
mathieu22: () -> PERMGRP I
++ mathieu22 constructs the mathieu group acting on the
++ integers 1,...,22.
mathieu23: L I -> PERMGRP I
++ mathieu23(li) constructs the mathieu group acting on the 23
++ integers given in the list {\em li}.
++ Note: duplicates in the list will be removed.
++ Error: if {\em li} has less or more than 23 different entries.
mathieu23: () -> PERMGRP I
++ mathieu23 constructs the mathieu group acting on the
++ integers 1,...,23.
mathieu24: L I -> PERMGRP I
++ mathieu24(li) constructs the mathieu group acting on the 24
++ integers given in the list {\em li}.
++ Note: duplicates in the list will be removed.
++ Error: if {\em li} has less or more than 24 different entries.
mathieu24: () -> PERMGRP I
++ mathieu24 constructs the mathieu group acting on the
++ integers 1,...,24.
janko2: L I -> PERMGRP I
++ janko2(li) constructs the janko group acting on the 100
++ integers given in the list {\em li}.

```

```

++ Note: duplicates in the list will be removed.
++ Error: if {\em li} has less or more than 100 different entries
janko2: () -> PERMGRP I
++ janko2 constructs the janko group acting on the
++ integers 1,...,100.
rubiksGroup: () -> PERMGRP I
++ rubiksGroup constructs the permutation group representing
++ Rubik's Cube acting on integers {\em 10*i+j} for
++ {\em 1 <= i <= 6}, {\em 1 <= j <= 8}.
++ The faces of Rubik's Cube are labelled in the obvious way
++ Front, Right, Up, Down, Left, Back and numbered from 1 to 6
++ in this given ordering, the pieces on each face
++ (except the unmoveable center piece) are clockwise numbered
++ from 1 to 8 starting with the piece in the upper left
++ corner. The moves of the cube are represented as permutations
++ on these pieces, represented as a two digit
++ integer {\em ij} where i is the number of the face (1 to 6)
++ and j is the number of the piece on this face.
++ The remaining ambiguities are resolved by looking
++ at the 6 generators, which represent a 90 degree turns of the
++ faces, or from the following pictorial description.
++ Permutation group representing Rubik's Cube acting on integers
++ 10*i+j for 1 <= i <= 6, 1 <= j <= 8.
++
++ \begin{verbatim}
++ Rubik's Cube: +-----+ +--- B where: marks Side # :
++ / U /|/
++ / / | F(ront) <-> 1
++ L --> +-----+ R| R(ight) <-> 2
++ | | + U(p) <-> 3
++ | F | / D(own) <-> 4
++ | | / L(eft) <-> 5
++ +-----+ B(ack) <-> 6
++ ^
++ |
++ D
++
++ The Cube's surface:
++
++ +----+
++ |567|
++ |4U8|
++ |321|
++ +-----+-----+
++ |781|123|345|
++ |6L2|8F4|2R6|
++
++ The pieces on each side
++ (except the unmoveable center
++ piece) are clockwise numbered
++ from 1 to 8 starting with the
++ piece in the upper left
++ corner (see figure on the
++ left). The moves of the cube
++ are represented as

```

```

++ |543|765|187| permutations on these pieces.
++ +---+---+---+ Each of the pieces is
++ |123| represented as a two digit
++ |8D4| integer ij where i is the
++ |765| # of the side (1 to 6 for
++ +---+ F to B (see table above))
++ |567| and j is the # of the piece.
++ |4B8|
++ |321|
++ +---+
++ \end{verbatim}
youngGroup: L I -> PERMGRP I
++ youngGroup([n1,...,nk]) constructs the direct product of the
++ symmetric groups {\em Sn1},...,{\em Snk}.
youngGroup: Partition -> PERMGRP I
++ youngGroup(lambda) constructs the direct product of the symmetric
++ groups given by the parts of the partition {\em lambda}.

++ Also See:
++ AMS Classifications:
++ Keywords: groebner basis, polynomial ideals
++ References:
++ Description:
++ Groebner functions for P F
++ This package is an interface package to the groebner basis
++ package which allows you to compute groebner bases for polynomials
++ in either lexicographic ordering or total degree ordering refined
++ by reverse lex. The input is the ordinary polynomial type which
++ is internally converted to a type with the required ordering.
++ The resulting grobner basis is converted back to ordinary polynomials.
++ The ordering among the variables is controlled by an explicit list
++ of variables which is passed as a second argument. The coefficient
++ domain is allowed to be any gcd domain, but the groebner basis is
++ computed as if the polynomials were over a field.

```

PolynomialNumberTheoryFunctions(): Exports == Implementation where
 I ==> Integer
 RN ==> Fraction I
 SUP ==> SparseUnivariatePolynomial
 NNI ==> NonNegativeInteger

Exports ==> with
 bernoulli : I -> SUP RN
 ++ bernoulli(n) returns the nth Bernoulli polynomial \spad{B[n](x)}.
 ++ Bernoulli polynomials denoted \spad{B(n,x)} computed by solving the
 ++ differential equation \spad{differentiate(B(n,x),x) = n B(n-1,x)} where

```

```

++ \spad{B(0,x) = 1} and initial condition comes from \spad{B(n) = B(n,0)}.
chebyshevT: I -> SUP I
++ chebyshevT(n) returns the nth Chebyshev polynomial \spad{T[n](x)}.
++ Note: Chebyshev polynomials of the first kind, denoted \spad{T[n](x)},
++ computed from the two term recurrence. The generating function
++ \spad{(1-t*x)/(1-2*t*x+t**2) = sum(T[n](x)*t**n, n=0..infinity)}.
chebyshevU: I -> SUP I
++ chebyshevU(n) returns the nth Chebyshev polynomial \spad{U[n](x)}.
++ Note: Chebyshev polynomials of the second kind, denoted \spad{U[n](x)},
++ computed from the two term recurrence. The generating function
++ \spad{1/(1-2*t*x+t**2) = sum(T[n](x)*t**n, n=0..infinity)}.
cyclotomic: I -> SUP I
++ cyclotomic(n) returns the nth cyclotomic polynomial \spad{phi[n](x)}.
++ Note: \spad{phi[n](x)} is the factor of \spad{x**n - 1} whose roots
++ are the primitive nth roots of unity.
euler : I -> SUP RN
++ euler(n) returns the nth Euler polynomial \spad{E[n](x)}.
++ Note: Euler polynomials denoted \spad{E(n,x)} computed by solving the
++ differential equation \spad{differentiate(E(n,x),x) = n E(n-1,x)} where
++ \spad{E(0,x) = 1} and initial condition comes from \spad{E(n) = 2**n E(n,1}
fixedDivisor: SUP I -> I
++ fixedDivisor(a) for \spad{a(x)} in \spad{Z[x]} is the largest integer
++ f such that f divides \spad{a(x=k)} for all integers k.
++ Note: fixed divisor of \spad{a} is
++ \spad{reduce(gcd,[a(x=k) for k in 0..degree(a)])}.
hermite : I -> SUP I
++ hermite(n) returns the nth Hermite polynomial \spad{H[n](x)}.
++ Note: Hermite polynomials, denoted \spad{H[n](x)}, are computed from
++ the two term recurrence. The generating function is:
++ \spad{exp(2*t*x-t**2) = sum(H[n](x)*t**n/n!, n=0..infinity)}.
laguerre : I -> SUP I
++ laguerre(n) returns the nth Laguerre polynomial \spad{L[n](x)}.
++ Note: Laguerre polynomials, denoted \spad{L[n](x)}, are computed from
++ the two term recurrence. The generating function is:
++ \spad{exp(x*t/(t-1))/(1-t) = sum(L[n](x)*t**n/n!, n=0..infinity)}.
legendre : I -> SUP RN
++ legendre(n) returns the nth Legendre polynomial \spad{P[n](x)}.
++ Note: Legendre polynomials, denoted \spad{P[n](x)}, are computed from
++ the two term recurrence. The generating function is:
++ \spad{1/sqrt(1-2*t*x+t**2) = sum(P[n](x)*t**n, n=0..infinity)}.

removeRedundantFactors: LP -> LP
++ \axiom{removeRedundantFactors(lp)} returns \axiom{lq} such that if
++ \axiom{lp = [p1,...,pn]} and \axiom{lq = [q1,...,qm]}
++ then the product \axiom{p1*p2*...*pn} vanishes iff the product \axiom{
++ and the product of degrees of the \axiom{qi} is not greater than
++ the one of the \axiom{pj}, and no polynomial in \axiom{lq}
++ divides another polynomial in \axiom{lq}. In particular,
++ polynomials lying in the base ring \axiom{R} are removed.
++ Moreover, \axiom{lq} is sorted w.r.t \axiom{infRittWu?}.
++ Furthermore, if R is gcd-domain, the polynomials in \axiom{lq} are
++ pairwise without common non trivial factor.
removeRedundantFactors: (P,P) -> LP
++ \axiom{removeRedundantFactors(p,q)} returns the same as
++ \axiom{removeRedundantFactors([p,q])}
removeSquaresIfCan : LP -> LP
++ \axiom{removeSquaresIfCan(lp)} returns
++ \axiom{removeDuplicates [squareFreePart(p)$P for p in lp]}
++ if \axiom{R} is gcd-domain else returns \axiom{lp}.

```

```

unprotectedRemoveRedundantFactors: (P,P) -> LP
 ++ \axiom{unprotectedRemoveRedundantFactors(p,q)} returns the same as
 ++ \axiom{removeRedundantFactors(p,q)} but does assume that neither
 ++ \axiom{p} nor \axiom{q} lie in the base ring \axiom{R} and assumes that
 ++ \axiom{infRittWu?(p,q)} holds. Moreover, if \axiom{R} is gcd-domain,
 ++ then \axiom{p} and \axiom{q} are assumed to be square free.
removeRedundantFactors: (LP,P) -> LP
 ++ \axiom{removeRedundantFactors(lp,q)} returns the same as
 ++ \axiom{removeRedundantFactors(cons(q,lp))} assuming
 ++ that \axiom{removeRedundantFactors(lp)} returns \axiom{lp}
 ++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
 ++ by some polynomial \axiom{qj} associated to \axiom{pj}.
removeRedundantFactors : (LP,LP) -> LP
 ++ \axiom{removeRedundantFactors(lp,lq)} returns the same as
 ++ \axiom{removeRedundantFactors(concat(lp,lq))} assuming
 ++ that \axiom{removeRedundantFactors(lp)} returns \axiom{lp}
 ++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
 ++ by some polynomial \axiom{qj} associated to \axiom{pj}.
removeRedundantFactors : (LP,LP,(LP -> LP)) -> LP
 ++ \axiom{removeRedundantFactors(lp,lq,remOp)} returns the same as
 ++ \axiom{concat(remOp(removeRoughlyRedundantFactorsInPols(lp,lq)),lq)}
 ++ assuming that \axiom{remOp(lq)} returns \axiom{lq} up to similarity.
certainlySubVariety? : (LP,LP) -> B
 ++ \axiom{certainlySubVariety?(newlp,lp)} returns true iff for every \axiom{p}
 ++ in \axiom{lp} the remainder of \axiom{p} by \axiom{newlp} using the division algo
 ++ of Groebner techniques is zero.
possiblyNewVariety? : (LP, List LP) -> B
 ++ \axiom{possiblyNewVariety?(newlp,llp)} returns true iff for every \axiom{lp}
 ++ in \axiom{llp} certainlySubVariety?(newlp,lp) does not hold.
probablyZeroDim?: LP -> B
 ++ \axiom{probablyZeroDim?(lp)} returns true iff the number of polynomials
 ++ in \axiom{lp} is not smaller than the number of variables occurring
 ++ in these polynomials.
selectPolynomials : ((P -> B),LP) -> Record(goodPols:LP,badPols:LP)
 ++ \axiom{selectPolynomials(pred?,ps)} returns \axiom{gps,bps} where
 ++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
 ++ such that \axiom{pred?(p)} holds and \axiom{bps} are the other ones.
selectOrPolynomials : (List (P -> B),LP) -> Record(goodPols:LP,badPols:LP)
 ++ \axiom{selectOrPolynomials(lpred?,ps)} returns \axiom{gps,bps} where
 ++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
 ++ such that \axiom{pred?(p)} holds for some \axiom{pred?} in \axiom{lpred?}
 ++ and \axiom{bps} are the other ones.
selectAndPolynomials : (List (P -> B),LP) -> Record(goodPols:LP,badPols:LP)
 ++ \axiom{selectAndPolynomials(lpred?,ps)} returns \axiom{gps,bps} where
 ++ \axiom{gps} is a list of the polynomial \axiom{p} in \axiom{ps}
 ++ such that \axiom{pred?(p)} holds for every \axiom{pred?} in \axiom{lpred?}

```

```

++ and \axiom{bps} are the other ones.
quasiMonicPolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \axiom{quasiMonicPolynomials(lp)} returns \axiom{qmps,nqmps} where
++ \axiom{qmps} is a list of the quasi-monic polynomials in \axiom{lp}
++ and \axiom{nqmps} are the other ones.
univariate? : P -> B
++ \axiom{univariate?(p)} returns true iff \axiom{p} involves one and
++ only one variable.
univariatePolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \axiom{univariatePolynomials(lp)} returns \axiom{ups,nups} where
++ \axiom{ups} is a list of the univariate polynomials,
++ and \axiom{nups} are the other ones.
linear? : P -> B
++ \axiom{linear?(p)} returns true iff \axiom{p} does not lie
++ in the base ring \axiom{R} and has main degree \axiom{1}.
linearPolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \axiom{linearPolynomials(lp)} returns \axiom{lps,nlps} where
++ \axiom{lps} is a list of the linear polynomials in lp,
++ and \axiom{nlps} are the other ones.
bivariate? : P -> B
++ \axiom{bivariate?(p)} returns true iff \axiom{p} involves two and
++ only two variables.
bivariatePolynomials : LP -> Record(goodPols:LP,badPols:LP)
++ \axiom{bivariatePolynomials(lp)} returns \axiom{bps,nbps} where
++ \axiom{bps} is a list of the bivariate polynomials,
++ and \axiom{nbps} are the other ones.
removeRoughlyRedundantFactorsInPols : (LP, LP) -> LP
++ \axiom{removeRoughlyRedundantFactorsInPols(lp,lf)} returns
++ \axiom{newlp} where \axiom{newlp} is obtained from \axiom{lp}
++ by removing in every polynomial \axiom{p} of \axiom{lp}
++ any occurrence of a polynomial \axiom{f} in \axiom{lf}.
++ This may involve a lot of exact-quotients computations.
removeRoughlyRedundantFactorsInPols : (LP, LP,B) -> LP
++ \axiom{removeRoughlyRedundantFactorsInPols(lp,lf,opt)} returns
++ the same as \axiom{removeRoughlyRedundantFactorsInPols(lp,lf)}
++ if \axiom{opt} is \axiom{false} and if the previous operation
++ does not return any non null and constant polynomial,
++ else return \axiom{[1]}.
removeRoughlyRedundantFactorsInPol : (P,LP) -> P
++ \axiom{removeRoughlyRedundantFactorsInPol(p,lf)} returns the same as
++ removeRoughlyRedundantFactorsInPols([p],lf,true)
interReduce: LP -> LP
++ \axiom{interReduce(lp)} returns \axiom{lq} such that \axiom{lp}
++ and \axiom{lq} generate the same ideal and no polynomial
++ in \axiom{lq} is reducible by the others in the sense
++ of Groebner bases. Since no assumptions are required

```

```

 ++ the result may depend on the ordering the reductions are
 ++ performed.
roughBasicSet: LP -> Union(Record(bas:T,top:LP),"failed")
 ++ \axiom{roughBasicSet(lp)} returns the smallest (with Ritt-Wu
 ++ ordering) triangular set contained in \axiom{lp}.
crushedSet: LP -> LP
 ++ \axiom{crushedSet(lp)} returns \axiom{lg} such that \axiom{lp} and
 ++ and \axiom{lg} generate the same ideal and no rough basic
 ++ sets reduce (in the sense of Groebner bases) the other
 ++ polynomials in \axiom{lg}.
rewriteSetByReducingWithParticularGenerators : (LP,(P->B),((P,P)->B),((P,P)->P)) -> LP
 ++ \axiom{rewriteSetByReducingWithParticularGenerators(lp,pred?,redOp?,redOp)}
 ++ returns \axiom{lg} where \axiom{lg} is computed by the following
 ++ algorithm. Chose a basic set w.r.t. the reduction-test \axiom{redOp?}
 ++ among the polynomials satisfying property \axiom{pred?},
 ++ if it is empty then leave, else reduce the other polynomials by
 ++ this basic set w.r.t. the reduction-operation \axiom{redOp}.
 ++ Repeat while another basic set with smaller rank can be computed.
 ++ See code. If \axiom{pred?} is \axiom{quasiMonic?} the ideal is unchanged.
rewriteIdealWithQuasiMonicGenerators : (LP,((P,P)->B),((P,P)->P)) -> LP
 ++ \axiom{rewriteIdealWithQuasiMonicGenerators(lp,redOp?,redOp)} returns
 ++ \axiom{lg} where \axiom{lg} and \axiom{lp} generate
 ++ the same ideal in \axiom{R-1 P} and \axiom{lg}
 ++ has rank not higher than the one of \axiom{lp}.
 ++ Moreover, \axiom{lg} is computed by reducing \axiom{lp}
 ++ w.r.t. some basic set of the ideal generated by
 ++ the quasi-monic polynomials in \axiom{lp}.
if R has GcdDomain
then
 squareFreeFactors : P -> LP
 ++ \axiom{squareFreeFactors(p)} returns the square-free factors of \axiom{p}
 ++ over \axiom{R}
 univariatePolynomialsGcds : LP -> LP
 ++ \axiom{univariatePolynomialsGcds(lp)} returns \axiom{lg} where
 ++ \axiom{lg} is a list of the gcds of every pair in \axiom{lp}
 ++ of univariate polynomials in the same main variable.
 univariatePolynomialsGcds : (LP,B) -> LP
 ++ \axiom{univariatePolynomialsGcds(lp,opt)} returns the same as
 ++ \axiom{univariatePolynomialsGcds(lp)} if \axiom{opt} is
 ++ \axiom{false} and if the previous operation does not return
 ++ any non null and constant polynomial, else return \axiom{[1]}.
 removeRoughlyRedundantFactorsInContents : (LP, LP) -> LP
 ++ \axiom{removeRoughlyRedundantFactorsInContents(lp,lf)} returns
 ++ \axiom{newlp} where \axiom{newlp} is obtained from \axiom{lp}
 ++ by removing in the content of every polynomial of \axiom{lp}
 ++ any occurrence of a polynomial \axiom{f} in \axiom{lf}. Moreover,

```

```

 ++ squares over \axiom{R} are first removed in the content
 ++ of every polynomial of \axiom{lp}.
removeRedundantFactorsInContents : (LP, LP) -> LP
 ++ \axiom{removeRedundantFactorsInContents(lp,lf)} returns \axiom{newlp}
 ++ where \axiom{newlp} is obtained from \axiom{lp} by removing
 ++ in the content of every polynomial of \axiom{lp} any non trivial
 ++ factor of any polynomial \axiom{f} in \axiom{lf}. Moreover,
 ++ squares over \axiom{R} are first removed in the content
 ++ of every polynomial of \axiom{lp}.
removeRedundantFactorsInPols : (LP, LP) -> LP
 ++ \axiom{removeRedundantFactorsInPols(lp,lf)} returns \axiom{newlp}
 ++ where \axiom{newlp} is obtained from \axiom{lp} by removing
 ++ in every polynomial \axiom{p} of \axiom{lp} any non trivial
 ++ factor of any polynomial \axiom{f} in \axiom{lf}. Moreover,
 ++ squares over \axiom{R} are first removed in every
 ++ polynomial \axiom{lp}.
if (R has EuclideanDomain) and (R has CharacteristicZero)
then
 irreducibleFactors : LP -> LP
 ++ \axiom{irreducibleFactors(lp)} returns \axiom{lf} such that if
 ++ \axiom{lp} = [p1,...,pn] and \axiom{lf} = [f1,...,fm] then
 ++ \axiom{p1*p2*...*pn=0} means \axiom{f1*f2*...*fm=0}, and the \axiom{f}
 ++ are irreducible over \axiom{R} and are pairwise distinct.
 lazyIrreducibleFactors : LP -> LP
 ++ \axiom{lazyIrreducibleFactors(lp)} returns \axiom{lf} such that if
 ++ \axiom{lp} = [p1,...,pn] and \axiom{lf} = [f1,...,fm] then
 ++ \axiom{p1*p2*...*pn=0} means \axiom{f1*f2*...*fm=0}, and the \axiom{f}
 ++ are irreducible over \axiom{R} and are pairwise distinct.
 ++ The algorithm tries to avoid factorization into irreducible
 ++ factors as far as possible and makes previously use of gcd
 ++ techniques over \axiom{R}.
 removeIrreducibleRedundantFactors : (LP, LP) -> LP
 ++ \axiom{removeIrreducibleRedundantFactors(lp,lq)} returns the same
 ++ as \axiom{irreducibleFactors(concat(lp,lq))} assuming
 ++ that \axiom{irreducibleFactors(lp)} returns \axiom{lp}
 ++ up to replacing some polynomial \axiom{pj} in \axiom{lp}
 ++ by some polynomial \axiom{qj} associated to \axiom{pj}.

 ++ denomRicDE(op) returns a polynomial \spad{d} such that any rational

```

```

++ solution of the associated Riccati equation of \spad{op y = 0} is
++ of the form \spad{p/d + q'/q + r} for some polynomials p and q
++ and a reduced r. Also, \spad{deg(p) < deg(d)} and {gcd(d,q) = 1}.
leadingCoefficientRicDE: L -> List REC
++ leadingCoefficientRicDE(op) returns
++ \spad{[[m1, p1], [m2, p2], ... , [mk, pk]]} such that the polynomial
++ part of any rational solution of the associated Riccati equation of
++ \spad{op y = 0} must have degree mj for some j, and its leading
++ coefficient is then a zero of pj. In addition, \spad{m1>m2> ... >mk}.
constantCoefficientRicDE: (L, UP -> List F) -> List CNT
++ constantCoefficientRicDE(op, ric) returns
++ \spad{[[a1, L1], [a2, L2], ... , [ak, Lk]]} such that any rational
++ solution with no polynomial part of the associated Riccati equation of
++ \spad{op y = 0} must be one of the ai's in which case the equation for
++ \spad{z = y e^{-int ai}} is \spad{Li z = 0}.
++ \spad{ric} is a Riccati equation solver over \spad{F}, whose input
++ is the associated linear equation.
polyRicDE: (L, UP -> List F) -> List POL
++ polyRicDE(op, zeros) returns
++ \spad{[[p1, L1], [p2, L2], ... , [pk, Lk]]} such that the polynomial
++ part of any rational solution of the associated Riccati equation of
++ \spad{op y=0} must be one of the pi's (up to the constant coefficient),
++ in which case the equation for \spad{z=y e^{-int p}} is \spad{Li z=0}.
++ \spad{zeros} is a zero finder in \spad{UP}.
singRicDE: (L, (UP, UP2) -> List UP, UP -> Factored UP) -> List FRC
++ singRicDE(op, zeros, ezfactor) returns
++ \spad{[[f1, L1], [f2, L2], ... , [fk, Lk]]} such that the singular
++ part of any rational solution of the associated Riccati equation of
++ \spad{op y=0} must be one of the fi's (up to the constant coefficient),
++ in which case the equation for \spad{z=y e^{-int p}} is \spad{Li z=0}.
++ \spad{zeros(C(x),H(x,y))} returns all the \spad{P_i(x)}'s such that
++ \spad{H(x,P_i(x)) = 0 modulo C(x)}.
++ Argument \spad{ezfactor} is a factorisation in \spad{UP},
++ not necessarily into irreducibles.
changeVar: (L, UP) -> L
++ changeVar(+/[ai D^i], a) returns the operator \spad{+/[ai (D+a)^i]}.
changeVar: (L, RF) -> L
++ changeVar(+/[ai D^i], a) returns the operator \spad{+/[ai (D+a)^i]}.

## 17.125 package PRS PseudoRemainderSequence

The package constructor **PseudoRemainderSequence** provides efficient algorithms by Lionel Ducos (University of Poitiers, France) for computing sub-resultants. This leads to a speed up in many places in Axiom where sub-resultants are computed (polynomial system solving, algebraic factorization, integration).

## 17.126 PseudoRemainderSequence

<package INTPAF PureAlgebraicIntegration>≡
)abbrev package INTPAF PureAlgebraicIntegration
++ Integration of pure algebraic functions;
++ Author: Manuel Bronstein
++ Date Created: 27 May 1988
++ Date Last Updated: 24 June 1994
++ Description:
++ This package provides functions for integration, limited integration,
++ extended integration and the risch differential equation for
++ pure algebraic integrands;
PureAlgebraicIntegration(R, F, L): Exports == Implementation where
 R: Join(GcdDomain,RetractableTo Integer,OrderedSet, CharacteristicZero,
 LinearlyExplicitRingOver Integer)
 F: Join(FunctionSpace R, AlgebraicallyClosedField,
 TranscendentalFunctionCategory)
 L: SetCategory

SY ==> Symbol
N ==> NonNegativeInteger

CHV ==> Record(int:UPUP, left:UP, right:UP, den:RF, deg:N)
U1 ==> Union(F, "failed")
U2 ==> Union(Record(ratpart:F, coeff:F), "failed")
U3 ==> Union(Record(mainpart:F, limitedlogs:List LOG), "failed")
FAIL==> error "failed - cannot handle that integrand"

Exports ==> with
 palgint : (F, K, K) -> IR
 ++ palgint(f, x, y) returns the integral of \spad{f(x,y)dx}
 ++ where y is an algebraic function of x.
 palgextint: (F, K, K, F) -> U2
 ++ palgextint(f, x, y, g) returns functions \spad{[h, c]} such that
 ++ \spad{dh/dx = f(x,y) - c g}, where y is an algebraic function of x;
 ++ returns "failed" if no such functions exist.
 palglimint: (F, K, K, List F) -> U3
 ++ palglimint(f, x, y, [u1,...,un]) returns functions
 ++ \spad{[h,[[ci, ui]]]} such that the ui's are among \spad{[u1,...,un]}
 ++ and \spad{d(h + sum(ci log(ui)))/dx = f(x,y)} if such functions exist,
 ++ "failed" otherwise;
 ++ y is an algebraic function of x.
 palgRDE : (F, F, F, K, K, (F, F, SY) -> U1) -> U1
 ++ palgRDE(nfp, f, g, x, y, foo) returns a function \spad{z(x,y)}
 ++ such that \spad{dz/dx + n * df/dx z(x,y) = g(x,y)} if such a z exists,
 ++ "failed" otherwise;
 ++ y is an algebraic function of x;
 ++ \spad{foo(a, b, x)} is a function that solves
 ++ \spad{du/dx + n * da/dx u(x) = u(x)}
 ++ for an unknown \spad{u(x)} not involving y.
 ++ \spad{nfp} is \spad{n * df/dx}.
 if L has LinearOrdinaryDifferentialOperatorCategory F then
 palgLODE: (L, F, K, K, SY) -> REC
 ++ palgLODE(op, g, kx, y, x) returns the solution of \spad{op f = g}.
 ++ y is an algebraic function of x.

### 18.1 package QALGSET2 QuasiAlgebraicSet2

### 18.2 QuasiAlgebraicSet2

#### Exports:

radicalSimplify

```
<package QALGSET2 QuasiAlgebraicSet2>≡
)abbrev package QALGSET2 QuasiAlgebraicSet2
++ Author: William Sit
++ Date Created: March 13, 1992
++ Date Last Updated: June 12, 1992
++ Basic Operations:
++ Related Constructors:GroebnerPackage, IdealDecompositionPackage,
++ PolynomialIdeals
++ See Also: QuasiAlgebraicSet
++ AMS Classifications:
++ Keywords: Zariski closed sets, quasi-algebraic sets
++ References:William Sit, "An Algorithm for Parametric Linear Systems"
```

```

++ J. Sym. Comp., April, 1992
++ Description:
++ \spadtype{QuasiAlgebraicSet2} adds a function \spadfun{radicalSimplify}
++ which uses \spadtype{IdealDecompositionPackage} to simplify
++ the representation of a quasi-algebraic set. A quasi-algebraic set
++ is the intersection of a Zariski
++ closed set, defined as the common zeros of a given list of
++ polynomials (the defining polynomials for equations), and a principal
++ Zariski open set, defined as the complement of the common
++ zeros of a polynomial f (the defining polynomial for the inequation).
++ Quasi-algebraic sets are implemented in the domain
++ \spadtype{QuasiAlgebraicSet}, where two simplification routines are
++ provided:
++ \spadfun{idealSimplify} and \spadfun{simplify}.
++ The function
++ \spadfun{radicalSimplify} is added
++ for comparison study only. Because the domain
++ \spadtype{IdealDecompositionPackage} provides facilities for
++ computing with radical ideals, it is necessary to restrict
++ the ground ring to the domain \spadtype{Fraction Integer},
++ and the polynomial ring to be of type
++ \spadtype{DistributedMultivariatePolynomial}.
++ The routine \spadfun{radicalSimplify} uses these to compute groebner
++ basis of radical ideals and
++ is inefficient and restricted when compared to the
++ two in \spadtype{QuasiAlgebraicSet}.

++ Factorization of extended polynomials with rational coefficients.
++ This package implements factorization of extended polynomials
++ whose coefficients are rational numbers. It does this by taking the
++ lcm of the coefficients of the polynomial and creating a polynomial
++ with integer coefficients. The algorithm in \spadtype{GaloisGroupFactorizer} is
++ used to factor the integer polynomial. The result is normalized
++ with respect to the original lcm of the denominators.

## 19.35 package RINTERP RationalInterpolation

### 19.35.1 Introduction

This file contains a crude naïve implementation of rational interpolation, where the coefficients of the rational function are in any given field.

### 19.35.2 Questions and Outlook

- Maybe this file should be joined with `pinterp.spad`, where polynomial Lagrange interpolation is implemented. I have a second version that parallels the structure of `pinterp.spad` closely.
- There are probably better ways to implement rational interpolation. Maybe <http://www.cs.ucsb.edu/~omer/personal/abstracts/rational.html> contains something useful, but I don't know.
- Comments welcome!

## 19.36 RationalInterpolation

### Exports:

`interpolate`

```

(package RINTERP RationalInterpolation)≡
)abbrev package RINTERP RationalInterpolation
++ Description:
++ This package exports rational interpolation algorithms
RationalInterpolation(xx,F): Exports == Implementation where
 xx: Symbol
 F: Field
Exports == with
 interpolate: (List F, List F, NonNegativeInteger,
 NonNegativeInteger) -> Fraction Polynomial F

```

The implementation sets up a system of linear equations and solves it.

```
<package RINTERP RationalInterpolation>+≡
 Implementation == add
 interpolate(xlist, ylist, m, k) ==
```

First we check whether we have the right number of points and values. Clearly the number of points and the number of values must be identical. Note that we want to determine the numerator and denominator polynomials only up to a factor. Thus, we want to determine  $m + k + 1$  coefficients, where  $m$  is the degree of the polynomial in the numerator and  $k$  is the degree of the polynomial in the denominator.

In fact, we could also leave – for example –  $k$  unspecified and determine it as  $k = \#xlist - m - 1$ : I don't know whether this would be better.

```
<package RINTERP RationalInterpolation>+≡
 #xlist ^= #ylist =>
 error "Different number of points and values."
 #xlist ^= m+k+1 =>
 error "wrong number of points"
```

$$\begin{aligned} p(x_1) - y_1 q(x_1) &= a_0 + a_1 x_1 + \dots + a_m x_1^m - y_1(b_0 + b_1 x_1 + \dots + b_k x_1^k) = 0 \\ p(x_2) - y_2 q(x_2) &= a_0 + a_1 x_2 + \dots + a_m x_2^m - y_2(b_0 + b_1 x_2 + \dots + b_k x_2^k) = 0 \\ &\vdots \\ p(x_n) - y_n q(x_n) &= a_0 + a_1 x_n + \dots + a_m x_n^m - y_n(b_0 + b_1 x_n + \dots + b_k x_n^k) = 0 \end{aligned}$$
$$\begin{bmatrix} 1 & x_1 & \dots & x_1^m & -y_1 & -y_1 x_1 & \dots & -y_1 x_1^k \\ 1 & x_2 & \dots & x_2^m & -y_2 & -y_2 x_2 & \dots & -y_2 x_2^k \\ & & & \vdots & & & & \\ 1 & x_n & \dots & x_n^m & -y_n & -y_n x_n & \dots & -y_n x_n^k \end{bmatrix} \begin{bmatrix} a_0 \\ a_1 \\ \vdots \\ a_m \\ b_0 \\ b_1 \\ \vdots \\ b_k \end{bmatrix} = \mathbf{0}$$

```

⟨package RINTERP RationalInterpolation⟩+≡
 tempvec: List F := [1 for i in 1..(m+k+1)]

 collist: List List F := cons(tempvec,
 [(tempvec := [tempvec.i * xlist.i _
 for i in 1..(m+k+1)]) _
 for j in 1..max(m,k)])

 collist := append([collist.j for j in 1..(m+1)], _
 [[- collist.j.i * ylist.i for i in 1..(m+k+1)] _
 for j in 1..(k+1)])

```

```

⟨package RINTERP RationalInterpolation⟩+=
 res: List Vector F := nullSpace((transpose matrix collist) _
 ::Matrix F)

```

```

⟨package RINTERP RationalInterpolation⟩+=
 if #res~1 then output("Warning: unattainable points!" _
 ::OutputForm)$OutputPackage

```

In this situation, all the solutions will be equivalent, thus we can always simply take the first one:

```
<package RINTERP RationalInterpolation>+≡
 reslist: List List Polynomial F := _
 [[(res.1).(i+1)*(xx::Polynomial F)**i for i in 0..m], _
 [(res.1).(i+m+2)*(xx::Polynomial F)**i for i in 0..k]]
```

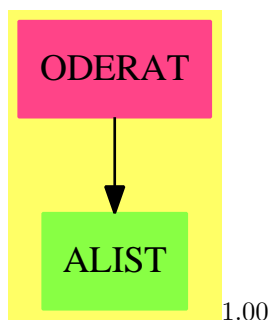

Finally, we generate the rational function:

```
<package RINTERP RationalInterpolation>+≡
 reduce((_+),reslist.1)/reduce((_+),reslist.2)

<RINTERP.dotabb>≡
 "RINTERP" [color="#FF4488",href="bookvol10.4.pdf#nameddest=RINTERP"]
 "PFECAT" [color="#4488FF",href="bookvol10.2.pdf#nameddest=PFECAT"]
 "RINTERP" -> "PFECAT"
```

Exports == with

```

rur: (LP,Boolean) -> List RUR
 ++ \spad{rur(lp,univ?) } returns a rational univariate representation
 ++ of \spad{lp}. This assumes that \spad{lp} defines a regular
 ++ triangular \spad{ts} whose associated variety is zero-dimensional
 ++ over \spad{R}. \spad{rur(lp,univ?) } returns a list of items
 ++ \spad{[u,lc]} where \spad{u} is an irreducible univariate polynomial
 ++ and each \spad{c} in \spad{lc} involves two variables: one from \spad{ls},
 ++ called the coordinate of \spad{c}, and an extra variable which
 ++ represents any root of \spad{u}. Every root of \spad{u} leads to
 ++ a tuple of values for the coordinates of \spad{lc}. Moreover,
 ++ a point \spad{x} belongs to the variety associated with \spad{lp} iff
 ++ there exists an item \spad{[u,lc]} in \spad{rur(lp,univ?) } and
 ++ a root \spad{r} of \spad{u} such that \spad{x} is given by the
 ++ tuple of values for the coordinates of \spad{lc} evaluated at \spad{r}.
 ++ If \spad{univ?} is \spad{true} then each polynomial \spad{c}
 ++ will have a constant leading coefficient w.r.t. its coordinate.
 ++ See the example which illustrates the \spadtype{ZeroDimensionalSolvePackage}
 ++ package constructor.
rur: (LP) -> List RUR
 ++ \spad{rur(lp)} returns the same as \spad{rur(lp,true)}
rur: (LP,Boolean,Boolean) -> List RUR
 ++ \spad{rur(lp,univ?,check?) } returns the same as \spad{rur(lp,true)}.
 ++ Moreover, if \spad{check?} is \spad{true} then the result is checked.

## 19.45 package POLUTIL RealPolynomialUtilitiesPackage

This file describes the Real Closure 1.0 package which consists of different packages, categories and domains :

The package RealPolynomialUtilitiesPackage which receives a field and a univariate polynomial domain with coefficients in the field. It computes some simple functions such as Strum and Sylvester sequences.

The category RealRootCharacterizationCategory provides abstract functionalities to work with "real roots" of univariate polynomials. These resemble variables with some functionalities needed to compute important operations.

RealClosedField is a category which provides common operations available over real closed fields. These include finding all the roots of univariate polynomial, taking square roots, ...

### CAVEATS

Since real algebraic expressions are stored as depending on "real roots" which are managed like variables, there is an ordering on these. This ordering is dynamical in the sense that any new algebraic takes precedence over older ones. In particular every creation function raises a new "real root". This has the effect that when you type something like  $\sqrt{2} + \sqrt{2}$  you have two new variables which happen to be equal. To avoid this name the expression such as in  $s2 := \sqrt{2} ; s2 + s2$

Also note that computing times depend strongly on the ordering you implicitly provide. Please provide algebraics in the order which is most natural to you.

### LIMITATIONS

The file `reclos.input` shows some basic use of the package. This package uses algorithms which are published in [1] and [2] which are based on field arithmetics, in particular for polynomial gcd related algorithms. This can be quite slow for high degree polynomials and subresultants methods usually work best. Beta versions of the package try to use these techniques in a better way and work significantly faster. These are mostly based on unpublished algorithms and cannot be distributed. Please contact the author if you have a particular problem to solve or want to use these versions.

Be aware that approximations behave as post-processing and that all computations are done exactly. They can thus be quite time consuming when depending on several "real roots".

## 19.55 package RECOP RecurrenceOperator

The package defined in this file provide an operator for the  $n^{th}$  term of a recurrence and an operator for the coefficient of  $x^n$  in a function specified by a functional equation.

## 19.56 RecurrenceOperator

### Exports:

```
getEq getOp evalADE evalRec
getShiftRec numberOfValuesNeeded shiftInfoRec
```

```
<package RECOP RecurrenceOperator>=
)abbrev package RECOP RecurrenceOperator
++ Author: Martin Rubey
++ Description:
++ This package provides an operator for the n-th term of a recurrence and an
++ operator for the coefficient of x^n in a function specified by a functional
++ equation.
RecurrenceOperator(R, F): Exports == Implementation where
 R: Join(OrderedSet, IntegralDomain, ConvertibleTo InputForm)
 F: Join(FunctionSpace R, AbelianMonoid, RetractableTo Integer, _
 RetractableTo Symbol, PartialDifferentialRing Symbol, _
 CombinatorialOpsCategory)
--RecurrenceOperator(F): Exports == Implementation where
-- F: Join(ExpressionSpace, AbelianMonoid, RetractableTo Integer,
-- RetractableTo Symbol, PartialDifferentialRing Symbol)

Exports == with

evalRec: (BasicOperator, Symbol, F, F, F, List F) -> F
++ \spad{evalRec(u, dummy, n, n0, eq, values)} creates an expression that
++ stands for u(n0), where u(n) is given by the equation eq. However, for
++ technical reasons the variable n has to be replaced by a dummy
++ variable dummy in eq. The argument values specifies the initial values
++ of the recurrence u(0), u(1),...
++ For the moment we don't allow recursions that contain u inside of
++ another operator.

evalADE: (BasicOperator, Symbol, F, F, F, List F) -> F
++ \spad{evalADE(f, dummy, x, n, eq, values)} creates an expression that
++ stands for the coefficient of x^n in the Taylor expansion of f(x),
```

```

++ where f(x) is given by the functional equation eq. However, for
++ technical reasons the variable x has to be replaced by a dummy
++ variable dummy in eq. The argument values specifies the first few
++ Taylor coefficients.

getEq: F -> F
++ \spad{getEq f} returns the defining equation, if f represents the
++ coefficient of an ADE or a recurrence.

getOp: F -> BasicOperator
++ \spad{getOp f}, if f represents the coefficient of a recurrence or
++ ADE, returns the operator representing the solution

-- should be local
numberOfValuesNeeded: (Integer, BasicOperator, Symbol, F) -> Integer

-- should be local
if R has Ring then
 getShiftRec: (BasicOperator, Kernel F, Symbol) -> Union(Integer, "failed")

 shiftInfoRec: (BasicOperator, Symbol, F) ->
 Record(max: Union(Integer, "failed"),
 ord: Union(Integer, "failed"),
 ker: Kernel F)

Implementation == add
<implementation: RecurrenceOperator>

```

### 19.56.1 Defining new operators

We define two new operators, one for recurrences, the other for functional equations. The operators for recurrences represents the  $n^{\text{th}}$  term of the corresponding sequence, the other the coefficient of  $x^n$  in the Taylor series expansion.

```

<implementation: RecurrenceOperator>≡
 oprecur := operator("rootOfRec"::Symbol)$BasicOperator

 opADE := operator("rootOfADE"::Symbol)$BasicOperator

 setProperty(oprecur, "%dummyVar", 2 pretend None)
 setProperty(opADE, "%dummyVar", 2 pretend None)

```

Setting these properties implies that the second and third arguments of `oprecur` are dummy variables and affects `tower$ES`: the second argument will not appear in `tower$ES`, if it does not appear in any argument but the first and second. The third argument will not appear in `tower$ES`, if it does not appear in any other argument. (`%defsum` is a good example)

The arguments of the two operators are as follows:

1. `eq`, i.e. the vanishing expression

```
<implementation: RecurrenceOperator>+≡
eqAsF: List F -> F
eqAsF 1 == 1.1
```

2. `dummy`, a dummy variable to make substitutions possible

```
<implementation: RecurrenceOperator>+≡
dummy: List F -> Symbol
dummy 1 == retract(1.2)@Symbol

dummyAsF: List F -> F
dummyAsF 1 == 1.2
```

3. the variable for display

```
<implementation: RecurrenceOperator>+≡
displayVariable: List F -> F
displayVariable 1 == 1.3
```

4. `operatorName(argument)`

```
<implementation: RecurrenceOperator>+≡
operatorName: List F -> BasicOperator
operatorName 1 == operator(kernels(1.4).1)

operatorNameAsF: List F -> F
operatorNameAsF 1 == 1.4

operatorArgument: List F -> F
operatorArgument 1 == argument(kernels(1.4).1).1
```

Concerning `rootOfADE`, note that although we have `arg` as argument of the operator, it is intended to indicate the coefficient, not the argument of the power series.

5. `values` in reversed order.

- `rootOfRec`: maybe `values` should be preceded by the index of the first given value. Currently, the last value is interpreted as  $f(0)$ .
- `rootOfADE`: values are the first few coefficients of the power series expansion in order.

```
⟨implementation: RecurrenceOperator⟩+≡
 initialValues: List F -> List F
 initialValues l == rest(l, 4)
```

## 19.56.2 Recurrences

### Extracting some information from the recurrence

We need to find out whether we can determine the next term of the sequence, and how many initial values are necessary.

```

<implementation: RecurrenceOperator> +=
 if R has Ring then
 getShiftRec(op: BasicOperator, f: Kernel F, n: Symbol)
 : Union(Integer, "failed") ==
 a := argument f
 if every?(freeOf?(#1, n::F), a) then return 0

 if #a ~= 1 then error "RECOP: operator should have only one argument"

 p := univariate(a.1, retract(n::F)@Kernel(F))
 if denominator p ~= 1 then return "failed"

 num := numer p

 if degree num = 1 and coefficient(num, 1) = 1
 and every?(freeOf?(#1, n::F), coefficients num)
 then return retractIfCan(coefficient(num, 0))
 else return "failed"

-- if the recurrence is of the form
-- $p(n, f(n+m-o), f(n+m-o+1), \dots, f(n+m)) = 0$
-- in which case shiftInfoRec returns [m, o, f(n+m)].

 shiftInfoRec(op: BasicOperator, argsym: Symbol, eq: F):
 Record(max: Union(Integer, "failed"),
 ord: Union(Integer, "failed"),
 ker: Kernel F) ==

-- ord and ker are valid only if all shifts are Integers
-- ker is the kernel of the maximal shift.
 maxShift: Integer
 minShift: Integer
 nextKernel: Kernel F

-- We consider only those kernels that have op as operator. If there is none,
-- we raise an error. For the moment we don't allow recursions that contain op
-- inside of another operator.

 error? := true

```

```

for f in kernels eq repeat
 if is?(f, op) then
 shift := getShiftRec(op, f, argsym)
 if error? then
 error? := false
 nextKernel := f
 if shift case Integer then
 maxShift := shift
 minShift := shift
 else return ["failed", "failed", nextKernel]
 else
 if shift case Integer then
 if maxShift < shift then
 maxShift := shift
 nextKernel := f
 if minShift > shift then
 minShift := shift
 else return ["failed", "failed", nextKernel]

if error? then error "evalRec: equation does not contain operator"

[maxShift, maxShift - minShift, nextKernel]

```

**Evaluating a recurrence**

```

<implementation: RecurrenceOperator> +=
 evalRec(op, argsym, argdisp, arg, eq, values) ==
 if ((n := retractIfCan(arg)@Union(Integer, "failed")) case "failed")
 or (n < 0)
 then
 shiftInfo := shiftInfoRec(op, argsym, eq)

 if (shiftInfo.ord case "failed") or ((shiftInfo.ord)::Integer > 0)
 then
 kernel(oprecur,
 append([eq, argsym::F, argdisp, op(arg)], values))
 else
 p := univariate(eq, shiftInfo.ker)
 num := numer p

-- If the degree is 1, we can return the function explicitly.

 if degree num = 1 then
 eval(-coefficient(num, 0)/coefficient(num, 1), argsym::F,
 arg::F-(shiftInfo.max)::Integer::F)
 else
 kernel(oprecur,
 append([eq, argsym::F, argdisp, op(arg)], values))
 else
 len: Integer := #values
 if n < len
 then values.(len-n)
 else
 shiftInfo := shiftInfoRec(op, argsym, eq)

 if shiftInfo.max case Integer then
 p := univariate(eq, shiftInfo.ker)

 num := numer p

 if degree num = 1 then

 next := -coefficient(num, 0)/coefficient(num, 1)
 nextval := eval(next, argsym::F,
 (len-(shiftInfo.max)::Integer)::F)
 newval := eval(nextval, op,
 evalRec(op, argsym, argdisp, #1, eq, values))
 evalRec(op, argsym, argdisp, arg, eq, cons(newval, values))
 else

```

```

 kernel(oprecur,
 append([eq, argsym::F, argdisp, op(arg)], values))

 else
 kernel(oprecur,
 append([eq, argsym::F, argdisp, op(arg)], values))

 numberOfValuesNeeded(numberOfValues: Integer,
 op: BasicOperator, argsym: Symbol, eq: F): Integer ==
 order := shiftInfoRec(op, argsym, eq).ord
 if order case Integer
 then min(numberOfValues, retract(order)@Integer)
 else numberOfValues

else
 evalRec(op, argsym, argdisp, arg, eq, values) ==
 kernel(oprecur,
 append([eq, argsym::F, argdisp, op(arg)], values))

 numberOfValuesNeeded(numberOfValues: Integer,
 op: BasicOperator, argsym: Symbol, eq: F): Integer ==
 numberOfValues

```

### Setting the evaluation property of oprecur

irecur is just a wrapper that allows us to write a recurrence relation as an operator.

```

<implementation: RecurrenceOperator>+≡
 irecur: List F -> F
 irecur l ==
 evalRec(operatorName l,
 dummy l, displayVariable l,
 operatorArgument l, eqAsF l, initialValues l)

 evaluate(oprecur, irecur)$BasicOperatorFunctions1(F)

```

**Displaying a recurrence relation**

```

<implementation: RecurrenceOperator>+≡
 ddrec: List F -> OutputForm
 ddrec l ==
 op := operatorName l
 values := reverse l
 eq := eqAsF l

 numberOfValues := numberOfValuesNeeded(#values-4, op, dummy l, eq)

 vals: List OutputForm
 := cons(eval(eq, dummyAsF l, displayVariable l)::OutputForm = _
 0::OutputForm,
 [elt(op::OutputForm, [(i-1)::OutputForm]) = _
 (values.i)::OutputForm
 for i in 1..numberOfValues])

 bracket(hconcat([(operatorNameAsF l)::OutputForm,
 ": ",
 commaSeparate vals])))

setProperty(oprecur, "%specialDisp",
 ddrec@(List F -> OutputForm) pretend None)

```

**19.56.3 Functional Equations****Determining the number of initial values for ADE's**

We use Joris van der Hoeven's instructions for ADE's. Given  $Q = p(f, f', \dots, f^{(r)})$  we first need to differentiate  $Q$  with respect to  $f^{(i)}$  for  $i \in \{0, 1, \dots, r\}$ , plug in the given truncated power series solution and determine the valuation.

```

<NOTYET implementation: RecurrenceOperator>≡
 getValuation(op, argsym, eq, maxorder, values): Integer ==
 max: Integer := -1;
 ker: Kernel F
 for i in 0..maxorder repeat
 ker := D(op(argsym), argsym, i)::Kernel F
 pol := univariate(eq, ker)
 dif := D pol
 ground numer(dif.D(op(argsym), argsym, i))

```

**Extracting some information from the functional equation**

`getOrder` returns the maximum derivative of `op` occurring in `f`.

```
<implementation: RecurrenceOperator>+≡
 getOrder(op: BasicOperator, f: Kernel F): NonNegativeInteger ==
 res: NonNegativeInteger := 0
 g := f
 while is?(g, %diff) repeat
 g := kernels(argument(g).1).1
 res := res+1

 if is?(g, op) then res else 0
```

**Extracting a coefficient given a functional equation**

```

<implementation: RecurrenceOperator>+≡

++ Date Last Updated: 12/16/1998
++ Basic Functions:
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ Description:
++ A package providing a new algorithm for solving polynomial systems
++ by means of regular chains. Two ways of solving are proposed:
++ in the sense of Zariski closure (like in Kalkbrener's algorithm)
++ or in the sense of the regular zeros (like in Wu, Wang or Lazard
++ methods). This algorithm is valid for any type
++ of regular set. It does not care about the way a polynomial is
++ added in a regular set, or how two quasi-components are compared
++ (by an inclusion-test), or how the invertibility test is made in
++ the tower of simple extensions associated with a regular set.
++ These operations are realized respectively by the domain \spad{TS}
++ and the packages
++ \axiomType{QCMACK}(R,E,V,P,TS) and \axiomType{RSETGCD}(R,E,V,P,TS).
++ The same way it does not care about the way univariate polynomial
++ gcd (with coefficients in the tower of simple extensions associated

```

```

++ with a regular set) are computed. The only requirement is that these
++ gcd need to have invertible initials (normalized or not).
++ WARNING. There is no need for a user to call directly any operation
++ of this package since they can be accessed by the domain \axiom{TS}.
++ Thus, the operations of this package are not documented.\newline

if R has commutative("*") then
 antisymmetricTensors : (M R,PI) -> M R
 ++ antisymmetricTensors(a,n) applies to the square matrix
 ++ {\em a} the irreducible, polynomial representation of the
 ++ general linear group {\em GLm}, where m is the number of
 ++ rows of {\em a}, which corresponds to the partition
 ++ {\em (1,1,...,1,0,0,...,0)} of n.
 ++ Error: if n is greater than m.
 ++ Note: this corresponds to the symmetrization of the representation
 ++ with the sign representation of the symmetric group {\em Sn}.
 ++ The carrier spaces of the representation are the antisymmetric
 ++ tensors of the n-fold tensor product.
if R has commutative("*") then
 antisymmetricTensors : (L M R, PI) -> L M R
 ++ antisymmetricTensors(la,n) applies to each
 ++ m-by-m square matrix in
 ++ the list {\em la} the irreducible, polynomial representation
 ++ of the general linear group {\em GLm}
 ++ which corresponds
 ++ to the partition {\em (1,1,...,1,0,0,...,0)} of n.
 ++ Error: if n is greater than m.
 ++ Note: this corresponds to the symmetrization of the representation
 ++ with the sign representation of the symmetric group {\em Sn}.
 ++ The carrier spaces of the representation are the antisymmetric

```

```

 ++ tensors of the n-fold tensor product.
createGenericMatrix : NNI -> M P R
 ++ createGenericMatrix(m) creates a square matrix of dimension k
 ++ whose entry at the i-th row and j-th column is the
 ++ indeterminate {\em x[i,j]} (double subscripted).
symmetricTensors : (M R, PI) -> M R
 ++ symmetricTensors(a,n) applies to the m-by-m
 ++ square matrix {\em a} the
 ++ irreducible, polynomial representation of the general linear
 ++ group {\em GLm}
 ++ which corresponds to the partition {\em (n,0,...,0)} of n.
 ++ Error: if {\em a} is not a square matrix.
 ++ Note: this corresponds to the symmetrization of the representation
 ++ with the trivial representation of the symmetric group {\em Sn}.
 ++ The carrier spaces of the representation are the symmetric
 ++ tensors of the n-fold tensor product.
symmetricTensors : (L M R, PI) -> L M R
 ++ symmetricTensors(la,n) applies to each m-by-m square matrix in the
 ++ list {\em la} the irreducible, polynomial representation
 ++ of the general linear group {\em GLm}
 ++ which corresponds
 ++ to the partition {\em (n,0,...,0)} of n.
 ++ Error: if the matrices in {\em la} are not square matrices.
 ++ Note: this corresponds to the symmetrization of the representation
 ++ with the trivial representation of the symmetric group {\em Sn}.
 ++ The carrier spaces of the representation are the symmetric
 ++ tensors of the n-fold tensor product.
tensorProduct : (M R, M R) -> M R
 ++ tensorProduct(a,b) calculates the Kronecker product
 ++ of the matrices {\em a} and b.
 ++ Note: if each matrix corresponds to a group representation
 ++ (repr. of generators) of one group, then these matrices
 ++ correspond to the tensor product of the two representations.
tensorProduct : (L M R, L M R) -> L M R
 ++ tensorProduct([a1,...,ak],[b1,...,bk]) calculates the list of
 ++ Kronecker products of the matrices {\em ai} and {\em bi}
 ++ for {1 <= i <= k}.
 ++ Note: If each list of matrices corresponds to a group representation
 ++ (repr. of generators) of one group, then these matrices
 ++ correspond to the tensor product of the two representations.
tensorProduct : M R -> M R
 ++ tensorProduct(a) calculates the Kronecker product
 ++ of the matrix {\em a} with itself.
tensorProduct : L M R -> L M R

++ their Realization in the Computer Algebra System Scratchpad,
++ Bayreuther Mathematische Schriften, Heft 33, 1990, 1-23.
++ Description:
++ RepresentationPackage2 provides functions for working with
++ modular representations of finite groups and algebra.
++ The routines in this package are created, using ideas of R. Parker,
++ (the meat-Axe) to get smaller representations from bigger ones,
++ i.e. finding sub- and factormodules, or to show, that such the

```

```

++ representations are irreducible.
++ Note: most functions are randomized functions of Las Vegas type
++ i.e. every answer is correct, but with small probability
++ the algorithm fails to get an answer.

public ==> with

completeEchelonBasis : V V R -> M R
++ completeEchelonBasis(lv) completes the basis {\em lv} assumed
++ to be in echelon form of a subspace of {\em R**n} (n the length
++ of all the vectors in {\em lv}) with unit vectors to a basis of
++ {\em R**n}. It is assumed that the argument is not an empty
++ vector and that it is not the basis of the 0-subspace.
++ Note: the rows of the result correspond to the vectors of the basis.
createRandomElement : (L M R, M R) -> M R
++ createRandomElement(aG,x) creates a random element of the group
++ algebra generated by {\em aG}.
-- randomWord : (L L I, L M) -> M R
--++ You can create your own 'random' matrix with "randomWord(lli, lm)".
--++ Each li in lli determines a product of matrices, the entries in li
--++ determine which matrix from lm is chosen. Finally we sum over all
--++ products. The result "sm" can be used to call split with (e.g.)
--++ second parameter "first nullSpace sm"
if R has EuclideanDomain then -- using rowEchelon
cyclicSubmodule : (L M R, V R) -> V V R
++ cyclicSubmodule(lm,v) generates a basis as follows.
++ It is assumed that the size n of the vector equals the number
++ of rows and columns of the matrices. Then the matrices generate
++ a subalgebra, say \spad{A}, of the algebra of all square matrices of
++ dimension n. {\em V R} is an \spad{A}-module in the natural way.
++ cyclicSubmodule(lm,v) generates the R-Basis of {\em Av} as
++ described in section 6 of R. A. Parker's "The Meat-Axe".
++ Note: in contrast to the description in "The Meat-Axe" and to

```

```

++ {\em standardBasisOfCyclicSubmodule} the result is in
++ echelon form.
standardBasisOfCyclicSubmodule : (L M R, V R) -> M R
++ standardBasisOfCyclicSubmodule(lm,v) returns a matrix as follows.
++ It is assumed that the size n of the vector equals the number
++ of rows and columns of the matrices. Then the matrices generate
++ a subalgebra, say \spad{A},
++ of the algebra of all square matrices of
++ dimension n. {\em V R} is an \spad{A}-module in the natural way.
++ standardBasisOfCyclicSubmodule(lm,v) calculates a matrix whose
++ non-zero column vectors are the R-Basis of {\em Av} achieved
++ in the way as described in section 6
++ of R. A. Parker's "The Meat-Axe".
++ Note: in contrast to {\em cyclicSubmodule}, the result is not
++ in echelon form.
if R has Field then -- only because of inverse in SM
areEquivalent? : (L M R, L M R, B, I) -> M R
++ areEquivalent?(aG0,aG1,randomelements,numberOfTries) tests
++ whether the two lists of matrices, all assumed of same
++ square shape, can be simultaneously conjugated by a non-singular
++ matrix. If these matrices represent the same group generators,
++ the representations are equivalent.
++ The algorithm tries
++ {\em numberOfTries} times to create elements in the
++ generated algebras in the same fashion. If their ranks differ,
++ they are not equivalent. If an
++ isomorphism is assumed, then
++ the kernel of an element of the first algebra
++ is mapped to the kernel of the corresponding element in the
++ second algebra. Now consider the one-dimensional ones.
++ If they generate the whole space (e.g. irreducibility !)
++ we use {\em standardBasisOfCyclicSubmodule} to create the
++ only possible transition matrix. The method checks whether the
++ matrix conjugates all corresponding matrices from {\em aGi}.
++ The way to choose the singular matrices is as in {\em meatAxe}.
++ If the two representations are equivalent, this routine
++ returns the transformation matrix {\em TM} with
++ {\em aG0.i * TM = TM * aG1.i} for all i. If the representations
++ are not equivalent, a small 0-matrix is returned.
++ Note: the case
++ with different sets of group generators cannot be handled.
areEquivalent? : (L M R, L M R) -> M R
++ areEquivalent?(aG0,aG1) calls {\em areEquivalent?(aG0,aG1,true,25)}.
++ Note: the choice of 25 was rather arbitrary.
areEquivalent? : (L M R, L M R, I) -> M R
++ areEquivalent?(aG0,aG1,numberOfTries) calls

```

```

++ {\em areEquivalent?(aG0,aG1,true,25)}.
++ Note: the choice of 25 was rather arbitrary.
isAbsolutelyIrreducible? : (L M R, I) -> B
++ isAbsolutelyIrreducible?(aG, numberOfTries) uses
++ Norton's irreducibility test to check for absolute
++ irreducibility, assuming if a one-dimensional kernel is found.
++ As no field extension changes create "new" elements
++ in a one-dimensional space, the criterium stays true
++ for every extension. The method looks for one-dimensionals only
++ by creating random elements (no fingerprints) since
++ a run of {\em meatAxe} would have proved absolute irreducibility
++ anyway.
isAbsolutelyIrreducible? : L M R -> B
++ isAbsolutelyIrreducible?(aG) calls
++ {\em isAbsolutelyIrreducible?(aG,25)}.
++ Note: the choice of 25 was rather arbitrary.
split : (L M R, V R) -> L L M R
++ split(aG, vector) returns a subalgebra \spad{A} of all
++ square matrix of dimension n as a list of list of matrices,
++ generated by the list of matrices aG, where n denotes both
++ the size of vector as well as the dimension of each of the
++ square matrices.
++ {\em V R} is an A-module in the natural way.
++ split(aG, vector) then checks whether the cyclic submodule
++ generated by {\em vector} is a proper submodule of {\em V R}.
++ If successful, it returns a two-element list, which contains
++ first the list of the representations of the submodule,
++ then the list of the representations of the factor module.
++ If the vector generates the whole module, a one-element list
++ of the old representation is given.
++ Note: a later version this should call the other split.
split: (L M R, V V R) -> L L M R
++ split(aG,submodule) uses a proper submodule of {\em R**n}
++ to create the representations of the submodule and of
++ the factor module.
if (R has Finite) and (R has Field) then
meatAxe : (L M R, B, I, I) -> L L M R
++ meatAxe(aG,randomElements,numberOfTries, maxTests) returns
++ a 2-list of representations as follows.
++ All matrices of argument aG are assumed to be square
++ and of equal size.
++ Then \spad{aG} generates a subalgebra, say \spad{A}, of the algebra
++ of all square matrices of dimension n. {\em V R} is an A-module
++ in the usual way.
++ meatAxe(aG,numberOfTries, maxTests) creates at most
++ {\em numberOfTries} random elements of the algebra, tests

```

```

++ them for singularity. If singular, it tries at most {\em maxTests}
++ elements of its kernel to generate a proper submodule.
++ If successful, a 2-list is returned: first, a list
++ containing first the list of the
++ representations of the submodule, then a list of the
++ representations of the factor module.
++ Otherwise, if we know that all the kernel is already
++ scanned, Norton's irreducibility test can be used either
++ to prove irreducibility or to find the splitting.
++ If {\em randomElements} is {\em false}, the first 6 tries
++ use Parker's fingerprints.
meatAxe : L M R -> L L M R
++ meatAxe(aG) calls {\em meatAxe(aG,false,25,7)} returns
++ a 2-list of representations as follows.
++ All matrices of argument \spad{aG} are assumed to be square
++ and of
++ equal size. Then \spad{aG} generates a subalgebra,
++ say \spad{A}, of the algebra
++ of all square matrices of dimension n. {\em V R} is an A-module
++ in the usual way.
++ meatAxe(aG) creates at most 25 random elements
++ of the algebra, tests
++ them for singularity. If singular, it tries at most 7
++ elements of its kernel to generate a proper submodule.
++ If successful a list which contains first the list of the
++ representations of the submodule, then a list of the
++ representations of the factor module is returned.
++ Otherwise, if we know that all the kernel is already
++ scanned, Norton's irreducibility test can be used either
++ to prove irreducibility or to find the splitting.
++ Notes: the first 6 tries use Parker's fingerprints.
++ Also, 7 covers the case of three-dimensional kernels over
++ the field with 2 elements.
meatAxe: (L M R, B) -> L L M R
++ meatAxe(aG, randomElements) calls {\em meatAxe(aG,false,6,7)},
++ only using Parker's fingerprints, if {\em randomElemnts} is false.
++ If it is true, it calls {\em meatAxe(aG,true,25,7)},
++ only using random elements.
++ Note: the choice of 25 was rather arbitrary.
++ Also, 7 covers the case of three-dimensional kernels over the field
++ with 2 elements.
meatAxe : (L M R, PI) -> L L M R
++ meatAxe(aG, numberOfTries) calls
++ {\em meatAxe(aG,true,numberOfTries,7)}.
++ Notes: 7 covers the case of three-dimensional
++ kernels over the field with 2 elements.

```

```

scanOneDimSubspaces: (L V R, I) -> V R
 ++ scanOneDimSubspaces(basis,n) gives a canonical representative
 ++ of the {\em n}-th one-dimensional subspace of the vector space
 ++ generated by the elements of {\em basis}, all from {\em R**n}.
 ++ The coefficients of the representative are of shape
 ++ {\em (0,...,0,1,...,*)}, {\em *} in R. If the size of R
 ++ is q, then there are {\em (q**n-1)/(q-1)} of them.
 ++ We first reduce n modulo this number, then find the
 ++ largest i such that {\em +/[q**i for i in 0..i-1] <= n}.
 ++ Subtracting this sum of powers from n results in an
 ++ i-digit number to basis q. This fills the positions of the
 ++ stars.

### 19.76 ResolveLatticeCompletion

#### Exports:

coerce

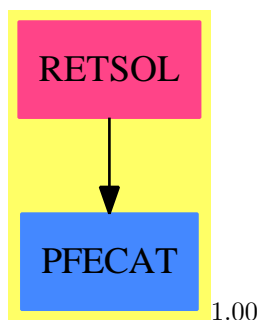

```

(package RESLATC ResolveLatticeCompletion)≡
)abbrev package RESLATC ResolveLatticeCompletion
++ Author: Stephen M. Watt
++ Date Created: 1986
++ Date Last Updated: May 30, 1991
++ Basic Operations:
++ Related Domains: ErrorFunctions, Exit, Void
++ Also See:
++ AMS Classifications:
++ Keywords: mode, resolve, type lattice
++ Examples:
++ References:
++ Description:
++ This package provides coercions for the special types \spadtype{Exit}
++ and \spadtype{Void}.
ResolveLatticeCompletion(S: Type): with
 coerce: S -> Void
 ++ coerce(s) throws all information about s away.
 ++ This coercion allows values of any type to appear
 ++ in contexts where they will not be used.
 ++ For example, it allows the resolution of different types in
 ++ the \spad{then} and \spad{else} branches when an \spad{if}
 ++ is in a context where the resulting value is not used.
 coerce: Exit -> S
 ++ coerce(e) is never really evaluated. This coercion is
 ++ used for formal type correctness when a function will not
 ++ return directly to its caller.

```

*(package SCACHE SortedCache)≡*

)abbrev package SCACHE SortedCache

++ Cache of elements in a set

++ Author: Manuel Bronstein

++ Date Created: 31 Oct 1988

++ Date Last Updated: 14 May 1991

++ A sorted cache of a cachable set S is a dynamic structure that

++ keeps the elements of S sorted and assigns an integer to each

++ element of S once it is in the cache. This way, equality and ordering

++ on S are tested directly on the integers associated with the elements

++ of S, once they have been entered in the cache.

SortedCache(S:CachableSet): Exports == Implementation where

N ==> NonNegativeInteger

DIFF ==> 1024

Exports ==> with

clearCache : () -> Void

++ clearCache() empties the cache.

cache : () -> List S

++ cache() returns the current cache as a list.

enterInCache: (S, S -> Boolean) -> S

++ enterInCache(x, f) enters x in the cache, calling \spad{f(y)} to

++ determine whether x is equal to y. It returns x with an integer

++ associated with it.

enterInCache: (S, (S, S) -> Integer) -> S

++ enterInCache(x, f) enters x in the cache, calling \spad{f(x, y)} to

++ determine whether \spad{x < y (f(x,y) < 0), x = y (f(x,y) = 0)}, or

++ \spad{x > y (f(x,y) > 0)}.

++ It returns x with an integer associated with it.

```

++ Keywords:
++ References:
++ Description:
++ This package lifts a mapping from coefficient rings R to S to
++ a mapping from sparse univariate polynomial over R to
++ a sparse univariate polynomial over S.
++ Note that the mapping is assumed
++ to send zero to zero, since it will only be applied to the non-zero
++ coefficients of the polynomial.

SparseUnivariatePolynomialFunctions2(R:Ring, S:Ring): with
 map: (R->S, SparseUnivariatePolynomial R) -> SparseUnivariatePolynomial S
 ++ map(func, poly) creates a new polynomial by applying func to
 ++ every non-zero coefficient of the polynomial poly.

++ AMS Classifications:
++ Keywords:
++ Description:
++ A package providing a new algorithm for solving polynomial systems
++ by means of regular chains. Two ways of solving are provided:
++ in the sense of Zariski closure (like in Kalkbrener's algorithm)
++ or in the sense of the regular zeros (like in Wu, Wang or Lazard-
++ Moreno methods). This algorithm is valid for nay type
++ of regular set. It does not care about the way a polynomial is
++ added in an regular set, or how two quasi-components are compared
++ (by an inclusion-test), or how the invertibility test is made in
++ the tower of simple extensions associated with a regular set.
++ These operations are realized respectively by the domain \spad{TS}
++ and the packages \spad{QCMPPK(R,E,V,P,TS)} and \spad{RSETGCD(R,E,V,P,TS)}.
++ The same way it does not care about the way univariate polynomial
++ gcds (with coefficients in the tower of simple extensions associated
++ with a regular set) are computed. The only requirement is that these

```

```

++ gcds need to have invertible initials (normalized or not).
++ WARNING. There is no need for a user to call directly any operation
++ of this package since they can be accessed by the domain \axiomType{TS}.
++ Thus, the operations of this package are not documented.\newline
++ References :
++ [1] M. MORENO MAZA "A new algorithm for computing triangular
++ decomposition of algebraic varieties" NAG Tech. Rep. 4/98.
++ Version: 2. Does not use any unproved criteria.

++ AMS Classifications:
++ Keywords:
++ Description:
++ A internal package for computing gcds and resultants of univariate polynomials
++ with coefficients in a tower of simple extensions of a field.
++ There is no need to use directly this package since its main operations are
++ available from \spad{TS}. \newline
++ References :

## 20.39 package STTAYLOR StreamTaylorSeriesOperations

Problems raising a UTS to a negative integer power.

The code in `powern(rn,x)` which raises an unnecessary error where no distinction between rational and integer powers are made.

The fix is easy. Since the problem does not exist in SUPS we can just take the definition there.

++ StreamTaylorSeriesOperations implements Taylor series arithmetic,
++ where a Taylor series is represented by a stream of its coefficients.
StreamTaylorSeriesOperations(A): Exports == Implementation where
 A : Ring
 RN ==> Fraction Integer
 I ==> Integer
 NNI ==> NonNegativeInteger
 ST ==> Stream
 SP2 ==> StreamFunctions2
 SP3 ==> StreamFunctions3
 L ==> List
 LA ==> List A
 YS ==> Y$ParadoxicalCombinatorsForStreams(A)
 UN ==> Union(ST A,"failed")
Exports ==> with
 "+" : (ST A,ST A) -> ST A
 ++ a + b returns the power series sum of \spad{a} and \spad{b}:
 ++ \spad{[a0,a1,...] + [b0,b1,...] = [a0 + b0,a1 + b1,...]}
 "-" : (ST A,ST A) -> ST A
 ++ a - b returns the power series difference of \spad{a} and
 ++ \spad{b}: \spad{[a0,a1,...] - [b0,b1,...] = [a0 - b0,a1 - b1,...]}
 "--" : ST A -> ST A
 ++ - a returns the power series negative of \spad{a}:
 ++ \spad{- [a0,a1,...] = [- a0,- a1,...]}
 "*" : (ST A,ST A) -> ST A
 ++ a * b returns the power series (Cauchy) product of \spad{a} and b:
 ++ \spad{[a0,a1,...] * [b0,b1,...] = [c0,c1,...]} where
 ++ \spad{ck = sum(i + j = k,ai * bk)}.
 "*" : (A,ST A) -> ST A
 ++ r * a returns the power series scalar multiplication of r by \spad{a}:
 ++ \spad{r * [a0,a1,...] = [r * a0,r * a1,...]}
 "*" : (ST A,A) -> ST A
 ++ a * r returns the power series scalar multiplication of \spad{a} by r:
 ++ \spad{[a0,a1,...] * r = [a0 * r,a1 * r,...]}
 "exquo" : (ST A,ST A) -> Union(ST A,"failed")
 ++ exquo(a,b) returns the power series quotient of \spad{a} by b,
 ++ if the quotient exists, and "failed" otherwise
 "/" : (ST A,ST A) -> ST A
 ++ a / b returns the power series quotient of \spad{a} by b.
 ++ An error message is returned if \spad{b} is not invertible.
 ++ This function is used in fixed point computations.
 recip : ST A -> UN
 ++ recip(a) returns the power series reciprocal of \spad{a}, or
 ++ "failed" if not possible.

```

```

monom : (A,I) -> ST A
 ++ monom(deg,coef) is a monomial of degree deg with coefficient
 ++ coef.
integers : I -> ST I
 ++ integers(n) returns \spad{[n,n+1,n+2,...]}.
oddintegers : I -> ST I
 ++ oddintegers(n) returns \spad{[n,n+2,n+4,...]}.
int : A -> ST A
 ++ int(r) returns [r,r+1,r+2,...], where r is a ring element.
mapmult : (ST A,ST A) -> ST A
 ++ mapmult([a0,a1,...],[b0,b1,...])
 ++ returns \spad{[a0*b0,a1*b1,...]}.
deriv : ST A -> ST A
 ++ deriv(a) returns the derivative of the power series with
 ++ respect to the power series variable. Thus
 ++ \spad{deriv([a0,a1,a2,...])} returns \spad{[a1,2 a2,3 a3,...]}.
gderiv : (I -> A,ST A) -> ST A
 ++ gderiv(f,[a0,a1,a2,...]) returns
 ++ \spad{[f(0)*a0,f(1)*a1,f(2)*a2,...]}.
coerce : A -> ST A
 ++ coerce(r) converts a ring element r to a stream with one element.
eval : (ST A,A) -> ST A
 ++ eval(a,r) returns a stream of partial sums of the power series
 ++ \spad{a} evaluated at the power series variable equal to r.
compose : (ST A,ST A) -> ST A
 ++ compose(a,b) composes the power series \spad{a} with
 ++ the power series b.
lagrange : ST A -> ST A
 ++ lagrange(g) produces the power series for f where f is
 ++ implicitly defined as \spad{f(z) = z*g(f(z))}.
revert : ST A -> ST A
 ++ revert(a) computes the inverse of a power series \spad{a}
 ++ with respect to composition.
 ++ the series should have constant coefficient 0 and first
 ++ order coefficient 1.
adddiag : ST ST A -> ST A
 ++ adddiag(x) performs diagonal addition of a stream of streams. if x =
 ++ \spad{[[a<0,0>,a<0,1>,...],[a<1,0>,a<1,1>,...],[a<2,0>,a<2,1>,...],...]}
 ++ and \spad{adddiag(x) = [b<0,b<1>,...]}, then b<k> = sum(i+j=k,a<i,j>)}.
lambert : ST A -> ST A
 ++ lambert(st) computes \spad{f(x) + f(x**2) + f(x**3) + ...}
 ++ if st is a stream representing \spad{f(x)}.
 ++ This function is used for computing infinite products.
 ++ If \spad{f(x)} is a power series with constant coefficient 1 then
 ++ \spad{prod(f(x**n),n = 1..infinity) = exp(lambert(log(f(x))))}.
oddlambert : ST A -> ST A

```

```

++ oddlambert(st) computes \spad{f(x) + f(x**3) + f(x**5) + ...}
++ if st is a stream representing \spad{f(x)}.
++ This function is used for computing infinite products.
++ If f(x) is a power series with constant coefficient 1 then
++ \spad{prod(f(x**(2*n-1)),n=1..infinity) = exp(oddlambert(log(f(x))))}.
evenlambert : ST A -> ST A
++ evenlambert(st) computes \spad{f(x**2) + f(x**4) + f(x**6) + ...}
++ if st is a stream representing \spad{f(x)}.
++ This function is used for computing infinite products.
++ If \spad{f(x)} is a power series with constant coefficient 1, then
++ \spad{prod(f(x**(2*n)),n=1..infinity) = exp(evenlambert(log(f(x))))}.
generalLambert : (ST A,I,I) -> ST A
++ generalLambert(f(x),a,d) returns
++ \spad{f(x**a) + f(x**(a + d)) + f(x**(a + 2 d)) + ...}.
++ \spad{f(x)} should have zero constant
++ coefficient and \spad{a} and d should be positive.
multisect : (I,I,ST A) -> ST A
++ multisect(a,b,st)
++ selects the coefficients of \spad{x**((a+b)*n+a)},
++ and changes them to \spad{x**n}.
invmultisect : (I,I,ST A) -> ST A
++ invmultisect(a,b,st) substitutes \spad{x**((a+b)*n)} for \spad{x**n}
++ and multiplies by \spad{x**b}.
if A has Algebra RN then
integrate : (A,ST A) -> ST A
++ integrate(r,a) returns the integral of the power series \spad{a}
++ with respect to the power series variable integration where
++ r denotes the constant of integration. Thus
++ \spad{integrate(a,[a0,a1,a2,...]) = [a,a0,a1/2,a2/3,...]}.
lazyIntegrate : (A,() -> ST A) -> ST A
++ lazyIntegrate(r,f) is a local function
++ used for fixed point computations.
nlde : ST ST A -> ST A
++ nlde(u) solves a
++ first order non-linear differential equation described by u of the
++ form \spad{[[b<0,0>,b<0,1>,...],[b<1,0>,b<1,1>,.,...]}
++ the differential equation has the form
++ \spad{y' = sum(i=0 to infinity,j=0 to infinity,b<i,j>*(x**i)*(y**j))}.
powern : (RN,ST A) -> ST A
++ powern(r,f) raises power series f to the power r.
if A has Field then
mapdiv : (ST A,ST A) -> ST A
++ mapdiv([a0,a1,...],[b0,b1,...]) returns
++ \spad{[a0/b0,a1/b1,...]}.
lazyGintegrate : (I -> A,A,() -> ST A) -> ST A
++ lazyGintegrate(f,r,g) is used for fixed point computations.

```

```

 power : (A,ST A) -> ST A
 ++ power(a,f) returns the power series f raised to the power \spad{a}.

++ Reference:

++ Description:

++ StructuralConstantsPackage provides functions creating  
++ structural constants from a multiplication tables or a basis  
++ of a matrix algebra and other useful functions in this context.

StructuralConstantsPackage(R:Field): public == private where

L ==> List

S ==> Symbol

FRAC ==> Fraction

POLY ==> Polynomial

V ==> Vector

M ==> Matrix

REC ==> Record(particular: Union(V R,"failed"),basis: List V R)

LSMP ==> LinearSystemMatrixPackage(R,V R,V R, M R)

public ==> with

```

-- what we really want to have here is a matrix over
-- linear polynomials in the list of symbols, having arbitrary
-- coefficients from a ring extension of R, e.g. FRAC POLY R.
structuralConstants : (L S, M FRAC POLY R) -> V M FRAC POLY R
 ++ structuralConstants(ls,mt) determines the structural constants
 ++ of an algebra with generators ls and multiplication table mt, the
 ++ entries of which must be given as linear polynomials in the
 ++ indeterminates given by ls. The result is in particular useful
 ++ as fourth argument for \spadtype{AlgebraGivenByStructuralConstants}
 ++ and \spadtype{GenericNonAssociativeAlgebra}.
structuralConstants : (L S, M POLY R) -> V M POLY R
 ++ structuralConstants(ls,mt) determines the structural constants
 ++ of an algebra with generators ls and multiplication table mt, the
 ++ entries of which must be given as linear polynomials in the
 ++ indeterminates given by ls. The result is in particular useful
 ++ as fourth argument for \spadtype{AlgebraGivenByStructuralConstants}
 ++ and \spadtype{GenericNonAssociativeAlgebra}.
structuralConstants: L M R -> V M R
 ++ structuralConstants(basis) takes the basis of a matrix
 ++ algebra, e.g. the result of \spadfun{basisOfCentroid} and calculates
 ++ the structural constants.
 ++ Note, that the it is not checked, whether basis really is a
 ++ basis of a matrix algebra.
coordinates: (M R, L M R) -> V R
 ++ coordinates(a,[v1,...,vn]) returns the coordinates of \spad{a}
 ++ with respect to the \spad{R}-module basis \spad{v1},...,\spad{vn}.

++ triangulate(M,v) returns
++ \spad{A,[[C_1,g_1,L_1,h_1],...,[C_k,g_k,L_k,h_k]]}
++ such that under the change of variable \spad{y = A z}, the first
++ order linear system \spad{D y = M y + v} is uncoupled as
++ \spad{D z_i = C_i z_i + g_i} and each \spad{C_i} is a companion
++ matrix corresponding to the scalar equation \spad{L_i z_j = h_i}.
triangulate: (M, V) -> REC
++ triangulate(m, v) returns \spad{[m_0, v_0]} such that \spad{m_0}
++ is upper triangular and the system \spad{m_0 x = v_0} is equivalent
++ to \spad{m x = v}.
solve: (MF,V,(LO,F)->USL) -> Union(Record(particular:V, basis:MF),"failed")
++ solve(m, v, solve) returns \spad{[[v_1,...,v_m], v_p]} such that
++ the solutions in \spad{F} of the system \spad{D x = m x + v} are
++ \spad{v_p + c_1 v_1 + ... + c_m v_m} where the \spad{c_i's} are
++ constants, and the \spad{v_i's} form a basis for the solutions of
++ \spad{D x = m x}.
++ Argument \spad{solve} is a function for solving a single linear
++ ordinary differential equation in \spad{F}.
solveInField: (M, V, (LO, F) -> FSL) -> VSL
++ solveInField(m, v, solve) returns \spad{[[v_1,...,v_m], v_p]} such
++ that the solutions in \spad{F} of the system \spad{m x = v} are
++ \spad{v_p + c_1 v_1 + ... + c_m v_m} where the \spad{c_i's} are
++ constants, and the \spad{v_i's} form a basis for the solutions of
++ \spad{m x = 0}.
++ Argument \spad{solve} is a function for solving a single linear
++ ordinary differential equation in \spad{F}.

++ Description:
++ Symbolic solver for systems of rational functions with coefficients
++ in an integral domain R.
++ The systems are solved in the field of rational functions over R.
++ Solutions are exact of the form variable = value when the value is
++ a member of the coefficient domain R. Otherwise the solutions
++ are implicitly expressed as roots of univariate polynomial equations over R.
++ Care is taken to guarantee that the denominators of the input
++ equations do not vanish on the solution sets.
++ The arguments to solve can either be given as equations or
++ as rational functions interpreted as equal
++ to zero. The user can specify an explicit list of symbols to
++ be solved for, treating all other symbols appearing as parameters
++ or omit the list of symbols in which case the system tries to
++ solve with respect to all symbols appearing in the input.

-- IS THERE A WORKING DOMAIN Tableau ??
-- coerce : M I -> Tableau(I)
-- ++ coerce(ytab) coerces the Young-Tableau ytab to an element of
-- ++ the domain Tableau(I).

```

```

coleman : (L I, L I, L I) -> M I
++ coleman(alpha,beta,pi):
++ there is a bijection from the set of matrices having nonnegative
++ entries and row sums {\em alpha}, column sums {\em beta}
++ to the set of {\em Salpha - Sbeta} double cosets of the
++ symmetric group {\em Sn}. ({\em Salpha} is the Young subgroup
++ corresponding to the improper partition {\em alpha}).
++ For a representing element {\em pi} of such a double coset,
++ coleman(alpha,beta,pi) generates the Coleman-matrix
++ corresponding to {\em alpha, beta, pi}.
++ Note: The permutation {\em pi} of {\em {1,2,...,n}} has to be given
++ in list form.
++ Note: the inverse of this map is {\em inverseColeman}
++ (if {\em pi} is the lexicographical smallest permutation
++ in the coset). For details see James/Kerber.
inverseColeman : (L I, L I, M I) -> L I
++ inverseColeman(alpha,beta,C):
++ there is a bijection from the set of matrices having nonnegative
++ entries and row sums {\em alpha}, column sums {\em beta}
++ to the set of {\em Salpha - Sbeta} double cosets of the
++ symmetric group {\em Sn}. ({\em Salpha} is the Young subgroup
++ corresponding to the improper partition {\em alpha}).

```

```

++ For such a matrix C, inverseColeman(alpha,beta,C)
++ calculates the lexicographical smallest {\em pi} in the
++ corresponding double coset.
++ Note: the resulting permutation {\em pi} of {\em {1,2,...,n}}
++ is given in list form.
++ Notes: the inverse of this map is {\em coleman}.
++ For details, see James/Kerber.
listYoungTableaus : (L I) -> L M I
++ listYoungTableaus(lambda) where {\em lambda} is a proper partition
++ generates the list of all standard tableaus of shape {\em lambda}
++ by means of lattice permutations. The numbers of the lattice
++ permutation are interpreted as column labels. Hence the
++ contents of these lattice permutations are the conjugate of
++ {\em lambda}.
++ Notes: the functions {\em nextLatticePermutation} and
++ {\em makeYoungTableau} are used.
++ The entries are from {\em 0,...,n-1}.
makeYoungTableau : (L I, L I) -> M I
++ makeYoungTableau(lambda,gitter) computes for a given lattice
++ permutation {\em gitter} and for an improper partition {\em lambda}
++ the corresponding standard tableau of shape {\em lambda}.
++ Notes: see {\em listYoungTableaus}.
++ The entries are from {\em 0,...,n-1}.
nextColeman : (L I, L I, M I) -> M I
++ nextColeman(alpha,beta,C) generates the next Coleman matrix
++ of column sums {\em alpha} and row sums {\em beta} according
++ to the lexicographical order from bottom-to-top.
++ The first Coleman matrix is achieved by {\em C=new(1,1,0)}.
++ Also, {\em new(1,1,0)} indicates that C is the last Coleman matrix.
nextLatticePermutation : (L I, L I, B) -> L I
++ nextLatticePermutation(lambda,lattP,constructNotFirst) generates
++ the lattice permutation according to the proper partition
++ {\em lambda} succeeding the lattice permutation {\em lattP} in
++ lexicographical order as long as {\em constructNotFirst} is true.
++ If {\em constructNotFirst} is false, the first lattice permutation
++ is returned.
++ The result {\em nil} indicates that {\em lattP} has no successor.
nextPartition : (V I, V I, I) -> V I
++ nextPartition(gamma,part,number) generates the partition of
++ {\em number} which follows {\em part} according to the right-to-left
++ lexicographical order. The partition has the property that
++ its components do not exceed the corresponding components of
++ {\em gamma}. The first partition is achieved by {\em part=[]}.
++ Also, {\em []} indicates that {\em part} is the last partition.
nextPartition : (L I, V I, I) -> V I
++ nextPartition(gamma,part,number) generates the partition of

```

```

++ {\em number} which follows {\em part} according to the right-to-left
++ lexicographical order. The partition has the property that
++ its components do not exceed the corresponding components of
++ {\em gamma}. the first partition is achieved by {\em part=[]}.
++ Also, {\em []} indicates that {\em part} is the last partition.
numberOfImproperPartitions: (I,I) -> I
++ numberOfImproperPartitions(n,m) computes the number of partitions
++ of the nonnegative integer n in m nonnegative parts with regarding
++ the order (improper partitions).
++ Example: {\em numberOfImproperPartitions (3,3)} is 10,
++ since {\em [0,0,3], [0,1,2], [0,2,1], [0,3,0], [1,0,2], [1,1,1],
++ [1,2,0], [2,0,1], [2,1,0], [3,0,0]} are the possibilities.
++ Note: this operation has a recursive implementation.
subSet : (I,I,I) -> L I
++ subSet(n,m,k) calculates the {\em k}-th {\em m}-subset of the set
++ {\em 0,1,...,(n-1)} in the lexicographic order considered as
++ a decreasing map from {\em 0,...,(m-1)} into {\em 0,...,(n-1)}.
++ See S.G. Williamson: Theorem 1.60.
++ Error: if not {\em (0 <= m <= n and 0 <= k < (n choose m))}.
unrankImproperPartitions0 : (I,I,I) -> L I
++ unrankImproperPartitions0(n,m,k) computes the {\em k}-th improper
++ partition of nonnegative n in m nonnegative parts in reverse
++ lexicographical order.
++ Example: {\em [0,0,3] < [0,1,2] < [0,2,1] < [0,3,0] <
++ [1,0,2] < [1,1,1] < [1,2,0] < [2,0,1] < [2,1,0] < [3,0,0]}.
++ Error: if k is negative or too big.
++ Note: counting of subtrees is done by
++ \spadfunFrom{numberOfImproperPartitions}{SymmetricGroupCombinatoricFunctions}.

unrankImproperPartitions1: (I,I,I) -> L I
++ unrankImproperPartitions1(n,m,k) computes the {\em k}-th improper
++ partition of nonnegative n in at most m nonnegative parts
++ ordered as follows: first, in reverse
++ lexicographically according to their non-zero parts, then
++ according to their positions (i.e. lexicographical order
++ using {\em subSet}: {\em [3,0,0] < [0,3,0] < [0,0,3] < [2,1,0] <
++ [2,0,1] < [0,2,1] < [1,2,0] < [1,0,2] < [0,1,2] < [1,1,1]}).
++ Note: counting of subtrees is done by
++ {\em numberOfImproperPartitionsInternal}.

## 21.7 package UTSSOL TaylorSolve

UTSSOL is a facility to compute the first few coefficients of a Taylor series given only implicitly by a function  $f$  that vanishes when applied to the Taylor series.

It uses the method of undetermined coefficients.

```
Could I either
\begin{itemize}
\item take a function $\text{UTSCAT}\ F \rightarrow \text{UTSCAT}\ F$ and still be able to compute
 with undetermined coefficients, or
\item take a function $\text{F} \rightarrow F$, and do likewise?
\end{itemize}
```

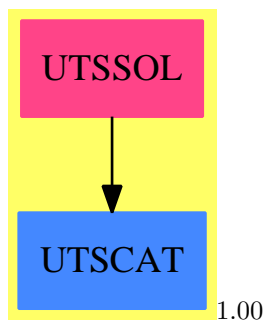

Let's see.

Try to compute the equation without resorting to power series. I.e., %  
 $\text{c}:\text{SUP}\ \text{SUP}\ F$ , and  $\text{f}:\text{SUP}\ \text{SUP}\ F \rightarrow \text{SUP}\ \text{SUP}\ F$ . Won't this make the  
 computation of coefficients terribly slow?

I could also try to replace transcendental kernels with variables\dots

Unfortunately,  $\text{SUP}\ F$  does not have  $\text{TRANFUN}$  -- well, it can't, of  
 course. However, I'd like to be able to compute %  
 $\sin(1+\text{monomial}(1,1))\text{UFPS}\ \text{SUP}\ \text{EXPR}\ \text{INT}$ .

## 21.8 TaylorSolve

### Exports:

seriesSolve

```

```
 F: Field
```

```
 SUP ==> SparseUnivariatePolynomialExpressions
```

```
 UTSF: UnivariateTaylorSeriesCategory F
```

```

UTSSUPF: UnivariateTaylorSeriesCategory SUP F
NNI ==> NonNegativeInteger

Exports == with
 seriesSolve: (UTSSUPF -> UTSSUPF, List F) -> UTSF

Implementation == add
<implementation: UTSSOL TaylorSolve>

<implementation: UTSSOL TaylorSolve>≡
 seriesSolve(f, l) ==
 c1 := map(#1::(SUP F), l)$ListFunctions2(F, SUP F)::(Stream SUP F)
 coeffs: Stream SUP F := concat(c1, generate(monomial(1$F,1$NNI)))
 --
 coeffs: Stream SUP F := concat(c1, monomial(1$F,1$NNI))

coeffs is the stream of the already computed coefficients of the solution, plus
one which is so far undetermined. We store in st.2 the complete stream and in
st.1 the stream starting with the first coefficient that has possibly not yet been
computed.

The mathematics is not quite worked out. If {\tt{}}coeffs is initialized as
stream with all coefficients set to the \emph{same} transcendental value,
and not enough initial values are given, then the missing ones are
implicitly assumed to be all identical. It may well happen that a solution
is produced, although it is not uniquely determined\dots

<implementation: UTSSOL TaylorSolve>+≡
 st: List Stream SUP F := [coeffs, coeffs]

```

Consider an arbitrary equation  $f(x, y(x)) = 0$ . When setting  $x = 0$ , we obtain  $f(0, y(0)) = 0$ . It is not necessarily the case that this determines  $y(0)$  uniquely, so we need one initial value that satisfies this equation.

`{\tt{seriesSolve}}` should check that the given initial values satisfy  $f(0, y(0), y'(0), \dots) = 0$ .

Now consider the derivatives of  $f$ , where we write  $y$  instead of  $y(x)$  for better readability:

$$\frac{d}{dx}f(x, y) = f_1(x, y) + f_2(x, y)y'$$

and

$$\begin{aligned} \frac{d^2}{dx^2}f(x, y) &= f_{1,1}(x, y) \\ &\quad + f_{1,2}(x, y)y' \\ &\quad + f_{2,1}(x, y)y' \\ &\quad + f_{2,2}(x, y)(y')^2 \\ &\quad + f_2(x, y)y'' \end{aligned}$$

In general,  $\frac{d^2}{dx^2}f(x, y)$  depends only linearly on  $y''$ .

This points to another possibility: Since we know that we only need to solve linear equations, we could compute two values and then use interpolation. This might be a bit slower, but more importantly: can we still check that we have enough initial values? Furthermore, we then really need that  $f$  is analytic, i.e., operators are not necessarily allowed anymore. However, it seems that composition is allowed.

```
<implementation: UTSSOL TaylorSolve>+≡
 next: () -> F :=
 nr := st.1
 res: F

 if ground?(coeff: SUP F := nr.1)$(SUP F)
```

If the next element was already calculated, we can simply return it:

```
<implementation: UTSSOL TaylorSolve>+≡
 then
 res := ground coeff
 st.1 := rest nr
 else
```

Otherwise, we have to find the first non-satisfied relation and solve it. It should be linear, or a single non-constant monomial. That is, the solution should be unique.

```

<implementation: UTSSOL TaylorSolve>+=
 ns := st.2
 eqs: Stream SUP F := coefficients f series ns
 while zero? first eqs repeat eqs := rest eqs
 eq: SUP F := first eqs
 if degree eq > 1 then
 if monomial? eq then res := 0
 else
 output(hconcat("The equation is: ", eq::OutputForm))
 $OutputPackage
 error "seriesSolve: equation for coefficient not line
 else res := (-coefficient(eq, 0$NNI)$(SUP F)
 /coefficient(eq, 1$NNI)$(SUP F))

 nr.1 := res::SUP F
-- concat!(st.2, monomial(1$F,1$NNI))
 st.1 := rest nr

Implementation ==> add

I have had to work my way around the following bug in the compiler: When a local variable is given a mapping as a value, e.g.

```
foo : SF -> SF := makeFloatFunction(f,t),
```

the compiler cannot distinguish that local variable from a local function defined elsewhere in the package. Thus, when 'foo' is passed to a function, e.g.

```
bird := fcn(foo),
```

foo will often be compiled as |DRAW;foo| rather than |foo|. This, of course, causes a run-time error.

To avoid this problem, local variables are not given mappings as values, but rather (singleton) lists of mappings. The first element of the list can always be extracted and everything goes through as before. There is no major loss in efficiency, as the computation of points will always dominate the computation time.

The function `myTrap1` is a local function for used in creating maps `SF -> Point SF` (two dimensional). The range of this function is `SingleFloat`. As originally coded it would return `$NaNvalue$Lisp` which is outside the range. Since this function is only used internally by the draw package we handle the “failed” case by returning zero. We handle the out-of-range case by returning the maximum or minimum `SingleFloat` value.

The function `myTrap2` is a local function for used in creating maps `SF -> Point SF` (three dimensional). The range of this function is `SingleFloat`. As originally coded it would return `$NaNvalue$Lisp` which is outside the range. Since this function is only used internally by the draw package we handle the “failed” case by returning zero. We handle the out-of-range case by returning the maximum or minimum `SingleFloat` value.

*(package DRAWCFUN TopLevelDrawFunctionsForCompiledFunctions)+≡*

Exports ==> with
expand : F -> F
 ++ expand(f) performs the following expansions on f:\begin{items}
 ++ \item 1. logs of products are expanded into sums of logs,
 ++ \item 2. trigonometric and hyperbolic trigonometric functions
 ++ of sums are expanded into sums of products of trigonometric
 ++ and hyperbolic trigonometric functions.
 ++ \item 3. formal powers of the form \spad{(a/b)**c} are expanded into
 ++ \spad{a**c * b**(-c)}.
 ++ \end{items}
simplify : F -> F
 ++ simplify(f) performs the following simplifications on f:\begin{items}
 ++ \item 1. rewrites trigs and hyperbolic trigs in terms
 ++ of \spad{sin} ,\spad{cos}, \spad{sinh}, \spad{cosh}.
 ++ \item 2. rewrites \spad{sin**2} and \spad{sinh**2} in terms
 ++ of \spad{cos} and \spad{cosh},
 ++ \item 3. rewrites \spad{exp(a)*exp(b)} as \spad{exp(a+b)}.
 ++ \item 4. rewrites \spad{(a**(1/n))**m * (a**(1/s))**t} as a single
 ++ power of a single radical of \spad{a}.
 ++ \end{items}
htrigs : F -> F
 ++ htrigs(f) converts all the exponentials in f into
 ++ hyperbolic sines and cosines.
simplifyExp: F -> F
 ++ simplifyExp(f) converts every product \spad{exp(a)*exp(b)}
 ++ appearing in f into \spad{exp(a+b)}.
simplifyLog : F -> F
 ++ simplifyLog(f) converts every \spad{log(a) - log(b)} appearing in f
 ++ into \spad{log(a/b)}, every \spad{log(a) + log(b)} into \spad{log(a*b)}
 ++ and every \spad{n*log(a)} into \spad{log(a^n)}.
expandPower: F -> F
 ++ expandPower(f) converts every power \spad{(a/b)**c} appearing
 ++ in f into \spad{a**c * b**(-c)}.
expandLog : F -> F
 ++ expandLog(f) converts every \spad{log(a/b)} appearing in f into
 ++ \spad{log(a) - log(b)}, and every \spad{log(a*b)} into
 ++ \spad{log(a) + log(b)}..
cos2sec : F -> F
 ++ cos2sec(f) converts every \spad{cos(u)} appearing in f into
 ++ \spad{1/sec(u)}.
cosh2sech : F -> F

```

```

 ++ cosh2sech(f) converts every \spad{cosh(u)} appearing in f into
 ++ \spad{1/sech(u)}.
cot2trig : F -> F
 ++ cot2trig(f) converts every \spad{cot(u)} appearing in f into
 ++ \spad{cos(u)/sin(u)}.
coth2trigh : F -> F
 ++ coth2trigh(f) converts every \spad{coth(u)} appearing in f into
 ++ \spad{cosh(u)/sinh(u)}.
csc2sin : F -> F
 ++ csc2sin(f) converts every \spad{csc(u)} appearing in f into
 ++ \spad{1/sin(u)}.
csch2sinh : F -> F
 ++ csch2sinh(f) converts every \spad{csch(u)} appearing in f into
 ++ \spad{1/sinh(u)}.
sec2cos : F -> F
 ++ sec2cos(f) converts every \spad{sec(u)} appearing in f into
 ++ \spad{1/cos(u)}.
sech2cosh : F -> F
 ++ sech2cosh(f) converts every \spad{sech(u)} appearing in f into
 ++ \spad{1/cosh(u)}.
sin2csc : F -> F
 ++ sin2csc(f) converts every \spad{sin(u)} appearing in f into
 ++ \spad{1/csc(u)}.
sinh2csch : F -> F
 ++ sinh2csch(f) converts every \spad{sinh(u)} appearing in f into
 ++ \spad{1/csch(u)}.
tan2trig : F -> F
 ++ tan2trig(f) converts every \spad{tan(u)} appearing in f into
 ++ \spad{sin(u)/cos(u)}.
tanh2trigh : F -> F
 ++ tanh2trigh(f) converts every \spad{tanh(u)} appearing in f into
 ++ \spad{sinh(u)/cosh(u)}.
tan2cot : F -> F
 ++ tan2cot(f) converts every \spad{tan(u)} appearing in f into
 ++ \spad{1/cot(u)}.
tanh2coth : F -> F
 ++ tanh2coth(f) converts every \spad{tanh(u)} appearing in f into
 ++ \spad{1/coth(u)}.
cot2tan : F -> F
 ++ cot2tan(f) converts every \spad{cot(u)} appearing in f into
 ++ \spad{1/tan(u)}.
coth2tanh : F -> F
 ++ coth2tanh(f) converts every \spad{coth(u)} appearing in f into
 ++ \spad{1/tanh(u)}.
removeCosSq: F -> F
 ++ removeCosSq(f) converts every \spad{cos(u)**2} appearing in f into

```

```

++ \spad{1 - sin(x)**2}, and also reduces higher
++ powers of \spad{cos(u)} with that formula.
removeSinSq: F -> F
++ removeSinSq(f) converts every \spad{sin(u)**2} appearing in f into
++ \spad{1 - cos(x)**2}, and also reduces higher powers of
++ \spad{sin(u)} with that formula.
removeCoshSq:F -> F
++ removeCoshSq(f) converts every \spad{cosh(u)**2} appearing in f into
++ \spad{1 - sinh(x)**2}, and also reduces higher powers of
++ \spad{cosh(u)} with that formula.
removeSinhSq:F -> F
++ removeSinhSq(f) converts every \spad{sinh(u)**2} appearing in f into
++ \spad{1 - cosh(x)**2}, and also reduces higher powers
++ of \spad{sinh(u)} with that formula.
if R has PatternMatchable(R) and R has ConvertibleTo(Pattern(R)) and F has Co
expandTrigProducts : F -> F
++ expandTrigProducts(e) replaces \axiom{sin(x)*sin(y)} by
++ \spad{(cos(x-y)-cos(x+y))/2}, \axiom{cos(x)*cos(y)} by
++ \spad{(cos(x-y)+cos(x+y))/2}, and \axiom{sin(x)*cos(y)} by
++ \spad{(sin(x-y)+sin(x+y))/2}. Note that this operation uses
++ the pattern matcher and so is relatively expensive. To avoid
++ getting into an infinite loop the transformations are applied
++ at most ten times.

solve

```

(package SOLVETRA TransSolvePackage)≡
)abbrev package SOLVETRA TransSolvePackage
++ Author: W. Wiwianka, Martin Rubey
++ Date Created: Summer 1991
++ Change History: 9/91
++ Basic Operations: solve
++ Related Constructors: RadicalSolvePackage, FloatingRealPackage
++ Keywords:
++ Description:
++ This package tries to find solutions of equations of type Expression(R).
++ This means expressions involving transcendental, exponential, logarithmic
++ and nthRoot functions.
++ After trying to transform different kernels to one kernel by applying
++ several rules, it calls zerosOf for the SparseUnivariatePolynomial in
++ the remaining kernel.
++ For example the expression \spad{sin(x)*cos(x)-2} will be transformed to
++ \spad{-2 tan(x/2)**4 -2 tan(x/2)**3 -4 tan(x/2)**2 +2 tan(x/2) -2}
++ by using the function normalize and then to
++ \spad{-2 tan(x)**2 + tan(x) -2}
++ with help of subsTan. This function tries to express the given function
++ in terms of \spad{tan(x/2)} to express in terms of \spad{tan(x)} .
++ Other examples are the expressions \spad{sqrt(x+1)+sqrt(x+7)+1} or
++ \spad{sqrt(sin(x))+1} .

++ Description:
++ Tools for constructing tubes around 3-dimensional parametric curves.
TubePlotTools(): Exports == Implementation where
 I ==> Integer
 SF ==> DoubleFloat
 L ==> List
 Pt ==> Point SF

Exports ==> with
 point: (SF,SF,SF,SF) -> Pt
 ++ point(x1,x2,x3,c) creates and returns a point from the three
 ++ specified coordinates \spad{x1}, \spad{x2}, \spad{x3}, and also
 ++ a fourth coordinate, c, which is generally used to specify the
 ++ color of the point.
 "*" : (SF,Pt) -> Pt
 ++ s * p returns a point whose coordinates are the scalar multiple
 ++ of the point p by the scalar s, preserving the color, or fourth
 ++ coordinate, of p.
 "+" : (Pt,Pt) -> Pt
 ++ p + q computes and returns a point whose coordinates are the sums

```

```

++ of the coordinates of the two points \spad{p} and \spad{q}, using
++ the color, or fourth coordinate, of the first point \spad{p}
++ as the color also of the point \spad{q}.
"-" : (Pt,Pt) -> Pt
++ p - q computes and returns a point whose coordinates are the
++ differences of the coordinates of two points \spad{p} and \spad{q},
++ using the color, or fourth coordinate, of the first point \spad{p}
++ as the color also of the point \spad{q}.
dot : (Pt,Pt) -> SF
++ dot(p,q) computes the dot product of the two points \spad{p}
++ and \spad{q} using only the first three coordinates, and returns
++ the resulting \spadtype{DoubleFloat}.
cross : (Pt,Pt) -> Pt
++ cross(p,q) computes the cross product of the two points \spad{p}
++ and \spad{q} using only the first three coordinates, and keeping
++ the color of the first point p. The result is returned as a point.
unitVector: Pt -> Pt
++ unitVector(p) creates the unit vector of the point p and returns
++ the result as a point. Note: \spad{unitVector(p) = p/|p|}.
cosSinInfo: I -> L L SF
++ cosSinInfo(n) returns the list of lists of values for n, in the
++ form: \spad{[[cos(n - 1) a,sin(n - 1) a],...,[cos 2 a,sin 2 a],[cos a,s
++ where \spad{a = 2 pi/n}. Note: n should be greater than 2.
loopPoints: (Pt,Pt,Pt,SF,L L SF) -> L Pt
++ loopPoints(p,n,b,r,lls) creates and returns a list of points
++ which form the loop with radius r, around the center point
++ indicated by the point p, with the principal normal vector of
++ the space curve at point p given by the point(vector) n, and the
++ binormal vector given by the point(vector) b, and a list of lists,
++ lls, which is the \spadfun{cosSinInfo} of the number of points
++ defining the loop.

)abbrev package TWOFACT TwoFactorize
++ Authors : P.Gianni, J.H.Davenport
++ Date Created : May 1990
++ Date Last Updated: March 1992
++ Description:
++ A basic package for the factorization of bivariate polynomials
++ over a finite field.
++ The functions here represent the base step for the multivariate factorizer.

TwoFactorize(F) : C == T
where
 F : FiniteFieldCategory
 SUP ==> SparseUnivariatePolynomial
 R ==> SUP F
 P ==> SUP R
 UPCF2 ==> UnivariatePolynomialCategoryFunctions2

C == with
 generalTwoFactor : (P) -> Factored P
 ++ generalTwoFactor(p) returns the factorisation of polynomial p,
 ++ a sparse univariate polynomial (sup) over a
 ++ sup over F.
 generalSqFr : (P) -> Factored P
 ++ generalSqFr(p) returns the square-free factorisation of polynomial p,
 ++ a sparse univariate polynomial (sup) over a
 ++ sup over F.
 twoFactor : (P,Integer) -> Factored P

```

```

 ++ twoFactor(p,n) returns the factorisation of polynomial p,
 ++ a sparse univariate polynomial (sup) over a
 ++ sup over F.
 ++ Also, p is assumed primitive and square-free and n is the
 ++ degree of the inner variable of p (maximum of the degrees
 ++ of the coefficients of p).

++ Basic Functions: squareFree, squareFreePart
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++ This package provides for square-free decomposition of
++ univariate polynomials over arbitrary rings, i.e.
++ a partial factorization such that each factor is a product
++ of irreducibles with multiplicity one and the factors are
++ pairwise relatively prime. If the ring
++ has characteristic zero, the result is guaranteed to satisfy
++ this condition. If the ring is an infinite ring of
++ finite characteristic, then it may not be possible to decide when
++ polynomials contain factors which are pth powers. In this
++ case, the flag associated with that polynomial is set to "nil"
++ (meaning that that polynomials are not guaranteed to be square-free).

O2 ==> FiniteLinearAggregateFunctions2(A, VA, B, VB)
UB ==> Union(B,"failed")

```

```

Exports ==> with

```

```

 scan : ((A, B) -> B, VA, B) -> VB
 ++ scan(func,vec,ident) creates a new vector whose elements are
 ++ the result of applying reduce to the binary function func,
 ++ increasing initial subsequences of the vector vec,
 ++ and the element ident.
 reduce : ((A, B) -> B, VA, B) -> B
 ++ reduce(func,vec,ident) combines the elements in vec using the
 ++ binary function func. Argument ident is returned if vec is empty.
 map : (A -> B, VA) -> VB
 ++ map(f, v) applies the function f to every element of the vector v
 ++ producing a new vector containing the values.
 map : (A -> UB, VA) -> Union(VB,"failed")
 ++ map(f, v) applies the function f to every element of the vector v
 ++ producing a new vector containing the values or \spad{"failed"}.

```

pointColorDefault : () -> PAL
++ pointColorDefault() returns the default color of points in a 2D
++ viewport.
pointColorDefault : PAL -> PAL
++ pointColorDefault(p) sets the default color of points in a 2D viewport
++ to the palette p.
lineColorDefault : () -> PAL
++ lineColorDefault() returns the default color of lines connecting
++ points in a 2D viewport.
lineColorDefault : PAL -> PAL
++ lineColorDefault(p) sets the default color of lines connecting points
++ in a 2D viewport to the palette p.
axesColorDefault : () -> PAL
++ axesColorDefault() returns the default color of the axes in a
++ 2D viewport.
axesColorDefault : PAL -> PAL
++ axesColorDefault(p) sets the default color of the axes in a 2D
++ viewport to the palette p.
unitsColorDefault : () -> PAL
++ unitsColorDefault() returns the default color of the unit ticks in
++ a 2D viewport.
unitsColorDefault : PAL -> PAL
++ unitsColorDefault(p) sets the default color of the unit ticks in
++ a 2D viewport to the palette p.
pointSizeDefault : () -> PI
++ pointSizeDefault() returns the default size of the points in
++ a 2D viewport.
pointSizeDefault : PI -> PI
++ pointSizeDefault(i) sets the default size of the points in a 2D
++ viewport to i.
viewPosDefault : () -> L NNI
++ viewPosDefault() returns the default X and Y position of a
++ viewport window unless overridden explicitly, newly created
++ viewports will have this X and Y coordinate.
viewPosDefault : L NNI -> L NNI
++ viewPosDefault([x,y]) sets the default X and Y position of a
++ viewport window unless overridden explicitly, newly created

```

```

 ++ viewports will have th X and Y coordinates x, y.
viewSizeDefault : () -> L PI
 ++ viewSizeDefault() returns the default viewport width and height.
viewSizeDefault : L PI -> L PI
 ++ viewSizeDefault([w,h]) sets the default viewport width to w and height
 ++ to h.
viewDefaults : () -> Void
 ++ viewDefaults() resets all the default graphics settings.
viewWriteDefault : () -> L S
 ++ viewWriteDefault() returns the list of things to write in a viewport
 ++ data file; a viewalone file is always generated.
viewWriteDefault : L S -> L S
 ++ viewWriteDefault(l) sets the default list of things to write in a
 ++ viewport data file to the strings in l; a viewalone file is always
 ++ generated.
viewWriteAvailable : () -> L S
 ++ viewWriteAvailable() returns a list of available methods for writing,
 ++ such as BITMAP, POSTSCRIPT, etc.
var1StepsDefault : () -> PI
 ++ var1StepsDefault() is the current setting for the number of steps to
 ++ take when creating a 3D mesh in the direction of the first defined
 ++ free variable (a free variable is considered defined when its
 ++ range is specified (e.g. x=0..10)).
var2StepsDefault : () -> PI
 ++ var2StepsDefault() is the current setting for the number of steps to
 ++ take when creating a 3D mesh in the direction of the first defined
 ++ free variable (a free variable is considered defined when its
 ++ range is specified (e.g. x=0..10)).
var1StepsDefault : PI -> PI
 ++ var1StepsDefault(i) sets the number of steps to take when creating a
 ++ 3D mesh in the direction of the first defined free variable to i
 ++ (a free variable is considered defined when its range is specified
 ++ (e.g. x=0..10)).
var2StepsDefault : PI -> PI
 ++ var2StepsDefault(i) sets the number of steps to take when creating a
 ++ 3D mesh in the direction of the first defined free variable to i
 ++ (a free variable is considered defined when its range is specified
 ++ (e.g. x=0..10)).
tubePointsDefault : PI -> PI
 ++ tubePointsDefault(i) sets the number of points to use when creating
 ++ the circle to be used in creating a 3D tube plot to i.
tubePointsDefault : () -> PI
 ++ tubePointsDefault() returns the number of points to be used when
 ++ creating the circle to be used in creating a 3D tube plot.
tubeRadiusDefault : Float -> SF -- current tube.spad asks for SF
 ++ tubeRadiusDefault(r) sets the default radius for a 3D tube plot to r.

```

```

tubeRadiusDefault : () -> SF
 ++ tubeRadiusDefault() returns the radius used for a 3D tube plot.

### 27.1 package ZDSOLVE ZeroDimensionalSolvePackage

Based on triangular decompositions and the **RealClosure** constructor, the package **ZeroDimensionalSolvePackage** provides operations for computing symbolically the real or complex roots of polynomial systems with finitely many solutions.

=====
ZeroDimensionalSolvePackage examples
=====
```

The ZeroDimensionalSolvePackage package constructor provides operations for computing symbolically the complex or real roots of zero-dimensional algebraic systems.

The package provides no multiplicity information (i.e. some returned roots may be double or higher) but only distinct roots are returned.

Complex roots are given by means of univariate representations of irreducible regular chains. These representations are computed by the univariateSolve operation (by calling the InternalRationalUnivariateRepresentationPackage package constructor which does the job).

Real roots are given by means of tuples of coordinates lying in the RealClosure of the coefficient ring. They are computed by the realSolve and positiveSolve operations. The former computes all the solutions of the input system with real coordinates whereas the later concentrate on the solutions with (strictly) positive coordinates. In both cases, the computations are performed by the RealClosure constructor.

Both computations of complex roots and real roots rely on triangular decompositions. These decompositions can be computed in two different ways. First, by applying the zeroSetSplit operation from the REGSET domain constructor. In that case, no Groebner bases are computed. This strategy is used by default. Secondly, by applying the zeroSetSplit from LEXTRIPK. To use this later strategy with the operations univariateSolve, realSolve and positiveSolve one just needs to use an extra boolean argument.

Note that the way of understanding triangular decompositions is detailed in the example of the RegularTriangularSet constructor.

The ZeroDimensionalSolvePackage constructor takes three arguments. The first one R is the coefficient ring; it must belong to the categories OrderedRing, EuclideanDomain, CharacteristicZero and RealConstant. This means essentially that R is Integer or Fraction(Integer). The second argument ls is the list of variables involved in the systems to solve. The third one MUST BE concat(ls,s) where s is an additional symbol used for the univariate representations. The abbreviation for ZeroDimensionalSolvePackage is ZDSOLVE.

We illustrate now how to use the constructor ZDSOLVE by two examples: the Arnborg and Lazard system and the L-3 system (Aubry and Moreno Maza). Note that the use of this package is also demonstrated in the example of the LexTriangularPackage constructor.

Define the coefficient ring.

```
R := Integer
Integer
Type: Domain
```

Define the lists of variables:

```
ls : List Symbol := [x,y,z,t]
[x,y,z,t]
Type: List Symbol
```

and:

```
ls2 : List Symbol := [x,y,z,t,new()$Symbol]
[x,y,z,t,%A]
Type: List Symbol
```

Call the package:

```
pack := ZDSOLVE(R,ls,ls2)
ZeroDimensionalSolvePackage(Integer,[x,y,z,t],[x,y,z,t,%A])
Type: Domain
```

Define a polynomial system (Arnborg-Lazard)

```
p1 := x**2*y*z + x*y**2*z + x*y*z**2 + x*y*z + x*y + x*z + y*z
 2 2 2
x y z + (x y + (x + x + 1)y + x)z + x y
Type: Polynomial Integer
```

```
p2 := x**2*y**2*z + x*y**2*z**2 + x**2*y*z + x*y*z + y*z + x + z
 2 2 2 2 2
x y z + (x y + (x + x + 1)y + 1)z + x
Type: Polynomial Integer
```

```
p3 := x**2*y**2*z**2 + x**2*y**2*z + x*y**2*z + x*y*z + x*z + z + 1
 2 2 2 2 2
x y z + ((x + x)y + x y + x + 1)z + 1
Type: Polynomial Integer
```

```

lp := [p1, p2, p3]
 2 2 2
[x y z + (x y + (x + x + 1)y + x)z + x y,
 2 2 2 2 2
x y z + (x y + (x + x + 1)y + 1)z + x,
 2 2 2 2 2
x y z + ((x + x)y + x y + x + 1)z + 1]
Type: List Polynomial Integer

```

Note that these polynomials do not involve the variable  $t$ ; we will use it in the second example.

First compute a decomposition into regular chains (i.e. regular triangular sets).

```

triangSolve(lp)$pack

]
Type: List RegularChain(Integer,[x,y,z,t])

```

We can see easily from this decomposition (consisting of a single regular chain) that the input system has 20 complex roots.

Then we compute a univariate representation of this regular chain.

```

Type: List Record(complexRoots: SparseUnivariatePolynomial Integer,
coordinates: List Polynomial Integer)

```

We see that the zeros of our regular chain are split into three components. This is due to the use of univariate polynomial factorization.

Each of these components consist of two parts. The first one is an irreducible univariate polynomial  $p(?)$  which defines a simple algebraic extension of the field of fractions of  $R$ . The second one consists of multivariate polynomials  $\text{pol1}(x,\%A)$ ,  $\text{pol2}(y,\%A)$  and  $\text{pol3}(z,\%A)$ . Each of these polynomials involve two variables: one is an indeterminate  $x$ ,  $y$  or  $z$  of the input system  $\text{lp}$  and the other is  $\%A$  which represents any root of  $p(?)$ . Recall that this  $\%A$  is the last element of the third parameter of ZDSOLVE. Thus any complex root  $?$  of  $p(?)$  leads to a solution of the input system  $\text{lp}$  by replacing  $\%A$  by this  $?$  in  $\text{pol1}(x,\%A)$ ,  $\text{pol2}(y,\%A)$  and  $\text{pol3}(z,\%A)$ . Note that the polynomials  $\text{pol1}(x,\%A)$ ,  $\text{pol2}(y,\%A)$  and  $\text{pol3}(z,\%A)$  have degree one w.r.t.  $x$ ,  $y$  or  $z$  respectively. This is always the case for all univariate representations. Hence the operation `univariateSolve` replaces a system of multivariate polynomials by a list of univariate polynomials, what justifies its name. Another example of univariate representations illustrates the `LexTriangularPackage` package constructor.

We now compute the solutions with real coordinates:

Type: List List RealClosure Fraction Integer

The number of real solutions for the input system is:

```

lr
 8

```

Type: PositiveInteger

Each of these real solutions is given by a list of elements in RealClosure(R). In these 8 lists, the first element is a value of  $z$ , the second of  $y$  and the last of  $x$ . This is logical since by setting the list of variables of the package to  $[x, y, z, t]$  we mean that the elimination ordering on the variables is  $t < z < y < x$ . Note that each system treated by the ZDSOLVE package constructor needs only to be zero-dimensional w.r.t. the variables involved in the system it-self and not necessarily w.r.t. all the variables used to define the package.

We can approximate these real numbers as follows. This computation takes between 30 sec. and 5 min, depending on your machine.

```

[[approximate(r,1/1000000) for r in point] for point in lr]

```

Type: List List Fraction Integer

We can also concentrate on the solutions with real (strictly) positive coordinates:

```

lpr := positiveSolve(lp)$pack
[]

```

Type: List List RealClosure Fraction Integer

Thus we have checked that the input system has no solution with strictly positive coordinates.

Let us define another polynomial system (L-3).

```

f0 := x**3 + y + z + t- 1
 3
 z + y + x + t - 1
 Type: Polynomial Integer

```

```

f1 := x + y**3 + z + t -1

 3 3 3 3 3 3 3
Type: List List RealClosure Fraction Integer

```

The number of real solutions for the input system is:

```

#l2r2
27
Type: PositiveInteger

```

Another example of computation of real solutions illustrates the LexTriangularPackage package constructor.

We concentrate now on the solutions with real (strictly) positive coordinates:

```

lpr2 := positiveSolve(lf)$pack
 1 3 1 1 3 1 1 3 1
[[%B40,- - %B40 + -, - - %B40 + -, - - %B40 + -]]
 3 3 3 3 3 3 3
Type: List List RealClosure Fraction Integer

```

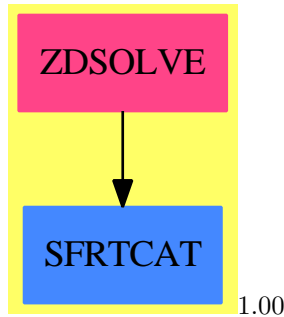

Finally, we approximate the coordinates of this point with 20 exact digits:

```
[approximate(r,1/10**21)::Float for r in lpr2.1]
[0.3221853546 2608559291, 0.3221853546 2608559291, 0.3221853546 2608559291,
 0.3221853546 2608559291]
Type: List Float
```

++ Author: Marc Moreno Maza
++ Date Created: 23/01/1999
++ Date Last Updated: 08/02/1999
++ Basic Functions:
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++ A package for computing symbolically the complex and real roots of
++ zero-dimensional algebraic systems over the integer or rational
++ numbers. Complex roots are given by means of univariate representations
++ of irreducible regular chains. Real roots are given by means of tuples
++ of coordinates lying in the \spadtype{RealClosure} of the coefficient ring.
++ This constructor takes three arguments. The first one \spad{R} is the
++ coefficient ring. The second one \spad{ls} is the list of variables involved
++ in the systems to solve. The third one must be \spad{concat(ls,s)} where
++ \spad{s} is an additional symbol used for the univariate representations.
++ WARNING: The third argument is not checked.
++ All operations are based on triangular decompositions.
++ The default is to compute these decompositions directly from the input
++ system by using the \spadtype{RegularChain} domain constructor.
++ The lexTriangular algorithm can also be used for computing these decompositions
++ (see the \spadtype{LexTriangularPackage} package constructor).
++ For that purpose, the operations \axiomOpFrom{univariateSolve}{ZeroDimensionalSolvePac
++ \axiomOpFrom{realSolve}{ZeroDimensionalSolvePackage} and
++ \axiomOpFrom{positiveSolve}{ZeroDimensionalSolvePackage} admit an optional
++ argument. \newline Author: Marc Moreno Maza.

 triangSolve: (LP,B,B) -> List RegularChain(R,ls)
 ++ \spad{triangSolve(lp,info?,lextri?)} decomposes the variety
 ++ associated with \axiom{lp} into regular chains.
 ++ Thus a point belongs to this variety iff it is a regular
 ++ zero of a regular set in in the output.
 ++ Note that \axiom{lp} needs to generate a zero-dimensional ideal.
 ++ If \axiom{lp} is not zero-dimensional then the result is only
 ++ a decomposition of its zero-set in the sense of the closure
 ++ (w.r.t. Zarisky topology).
```

```

++ Moreover, if \spad{info?} is \spad{true} then some information is
++ displayed during the computations.
++ See \axiomOpFrom{zeroSetSplit}{RegularTriangularSetCategory}(lp,true,info?).
++ If \spad{lextri?} is \spad{true} then the lexTriangular algorithm is called
++ from the \spadtype{LexTriangularPackage} constructor
++ (see \axiomOpFrom{zeroSetSplit}{LexTriangularPackage}(lp,false)).
++ Otherwise, the triangular decomposition is computed directly from the input
++ system by using the \axiomOpFrom{zeroSetSplit}{RegularChain} from \spadtype{RegularChain}
triangSolve: (LP,B) -> List RegularChain(R,ls)
++ \spad{triangSolve(lp,info?)} returns the same as \spad{triangSolve(lp,false)}
triangSolve: LP -> List RegularChain(R,ls)
++ \spad{triangSolve(lp)} returns the same as \spad{triangSolve(lp,false,false)}
univariateSolve: RegularChain(R,ls) -> List Record(complexRoots: U, coordinates: LP)
++ \spad{univariateSolve(ts)} returns a univariate representation
++ of \spad{ts}.
++ See \axiomOpFrom{rur}{RationalUnivariateRepresentationPackage}(lp,true).
univariateSolve: (LP,B,B,B) -> List RUR
++ \spad{univariateSolve(lp,info?,check?,lextri?)} returns a univariate
++ representation of the variety associated with \spad{lp}.
++ Moreover, if \spad{info?} is \spad{true} then some information is
++ displayed during the decomposition into regular chains.
++ If \spad{check?} is \spad{true} then the result is checked.
++ See \axiomOpFrom{rur}{RationalUnivariateRepresentationPackage}(lp,true).
++ If \spad{lextri?} is \spad{true} then the lexTriangular algorithm is called
++ from the \spadtype{LexTriangularPackage} constructor
++ (see \axiomOpFrom{zeroSetSplit}{LexTriangularPackage}(lp,false)).
++ Otherwise, the triangular decomposition is computed directly from the input
++ system by using the \axiomOpFrom{zeroSetSplit}{RegularChain} from \spadtype{RegularChain}
univariateSolve: (LP,B,B) -> List RUR
++ \spad{univariateSolve(lp,info?,check?)} returns the same as
++ \spad{univariateSolve(lp,info?,check?,false)}.
univariateSolve: (LP,B) -> List RUR
++ \spad{univariateSolve(lp,info?)} returns the same as
++ \spad{univariateSolve(lp,info?,false,false)}.
univariateSolve: LP -> List RUR
++ \spad{univariateSolve(lp)} returns the same as
++ \spad{univariateSolve(lp,false,false,false)}.
realSolve: RegularChain(R,ls) -> List REALSOL
++ \spad{realSolve(ts)} returns the set of the points in the regular
++ zero set of \spad{ts} whose coordinates are all real.
++ WARNING: For each set of coordinates given by \spad{realSolve(ts)}
++ the ordering of the indeterminates is reversed w.r.t. \spad{ls}.
realSolve: (LP,B,B,B) -> List REALSOL
++ \spad{realSolve(ts,info?,check?,lextri?)} returns the set of the points
++ in the variety associated with \spad{lp} whose coordinates are all real.
++ Moreover, if \spad{info?} is \spad{true} then some information is

```

```

++ displayed during decomposition into regular chains.
++ If \spad{check?} is \spad{true} then the result is checked.
++ If \spad{lextri?} is \spad{true} then the lexTriangular algorithm is ca
++ from the \spadtype{LexTriangularPackage} constructor
++ (see \axiomOpFrom{zeroSetSplit}{LexTriangularPackage}(lp,false)).
++ Otherwise, the triangular decomposition is computed directly from the i
++ system by using the \axiomOpFrom{zeroSetSplit}{RegularChain} from \spad
++ WARNING: For each set of coordinates given by \spad{realSolve(ts,info?,
++ the ordering of the indeterminates is reversed w.r.t. \spad{ls}.
realSolve: (LP,B,B) -> List REALSOL
++ \spad{realSolve(ts,info?,check?) returns the same as \spad{realSolve(t
realSolve: (LP,B) -> List REALSOL
++ \spad{realSolve(ts,info?) returns the same as \spad{realSolve(ts,info?
realSolve: LP -> List REALSOL
++ \spad{realSolve(lp)} returns the same as \spad{realSolve(ts,false,false
positiveSolve: RegularChain(R,ls) -> List REALSOL
++ \spad{positiveSolve(ts)} returns the points of the regular
++ set of \spad{ts} with (real) strictly positive coordinates.
positiveSolve: (LP,B,B) -> List REALSOL
++ \spad{positiveSolve(lp,info?,lextri?) returns the set of the points
++ in the variety associated with \spad{lp} whose coordinates are (real) s
++ Moreover, if \spad{info?} is \spad{true} then some information is
++ displayed during decomposition into regular chains.
++ If \spad{lextri?} is \spad{true} then the lexTriangular algorithm is ca
++ from the \spadtype{LexTriangularPackage} constructor
++ (see \axiomOpFrom{zeroSetSplit}{LexTriangularPackage}(lp,false)).
++ Otherwise, the triangular decomposition is computed directly from the i
++ system by using the \axiomOpFrom{zeroSetSplit}{RegularChain} from \spad
++ WARNING: For each set of coordinates given by \spad{positiveSolve(lp,in
++ the ordering of the indeterminates is reversed w.r.t. \spad{ls}.
positiveSolve: (LP,B) -> List REALSOL
++ \spad{positiveSolve(lp)} returns the same as \spad{positiveSolve(lp,inf
positiveSolve: LP -> List REALSOL
++ \spad{positiveSolve(lp)} returns the same as \spad{positiveSolve(lp,fal
squareFree: (TS) -> List ST
++ \spad{squareFree(ts)} returns the square-free factorization of \spad{ts}
++ Moreover, each factor is a Lazard triangular set and the decomposition
++ is a Kalkbrener split of \spad{ts}, which is enough here for
++ the matter of solving zero-dimensional algebraic systems.
++ WARNING: \spad{ts} is not checked to be zero-dimensional.
convert: Q -> Q2
++ \spad{convert(q)} converts \spad{q}.
convert: P -> PRC
++ \spad{convert(p)} converts \spad{p}.
convert: Q2 -> PRC
++ \spad{convert(q)} converts \spad{q}.

```

```

convert: U -> URC
 ++ \spad{convert(u)} converts \spad{u}.
convert: ST -> List Q2
 ++ \spad{convert(st)} returns the members of \spad{st}.

```

```
