++ Description:
++ \spadtype{MultiVariableCalculusFunctions} Package provides several
++ functions for multivariable calculus.
++ These include gradient, hessian and jacobian,
++ divergence and laplacian.
++ Various forms for banded and sparse storage of matrices are
++ included.
MultiVariableCalculusFunctions(S,F,FLAF,FLAS) : Exports == Implementation where
  PI ==> PositiveInteger
  NNI ==> NonNegativeInteger

S: SetCategory
F: PartialDifferentialRing(S)
FLAS: FiniteLinearAggregate(S)
  with finiteAggregate
  
```

FLAF: FiniteLinearAggregate(F)

Exports ==> with

```

gradient: (F,FLAS) -> Vector F
++ \spad{gradient(v,xlist)}
++ computes the gradient, the vector of first partial derivatives,
++ of the scalar field v,
++ v a function of the variables listed in xlist.
divergence: (FLAF,FLAS) -> F
++ \spad{divergence(vf,xlist)}
++ computes the divergence of the vector field vf,
++ vf a vector function of the variables listed in xlist.
laplacian: (F,FLAS) -> F
++ \spad{laplacian(v,xlist)}
++ computes the laplacian of the scalar field v,
++ v a function of the variables listed in xlist.
hessian: (F,FLAS) -> Matrix F
++ \spad{hessian(v,xlist)}
++ computes the hessian, the matrix of second partial derivatives,
++ of the scalar field v,
++ v a function of the variables listed in xlist.
bandedHessian: (F,FLAS,NNI) -> Matrix F
++ \spad{bandedHessian(v,xlist,k)}
++ computes the hessian, the matrix of second partial derivatives,
++ of the scalar field v,
++ v a function of the variables listed in xlist,
++ k is the semi-bandwidth, the number of nonzero subdiagonals,
++ 2*k+1 being actual bandwidth.
++ Stores the nonzero band in lower triangle in a matrix,
++ dimensions k+1 by #xlist,
++ whose rows are the vectors formed by diagonal, subdiagonal, etc.
++ of the real, full-matrix, hessian.
++ (The notation conforms to LAPACK/NAG-F07 conventions.)
-- At one stage it seemed a good idea to help the ASP<n> domains
-- with the types of their input arguments and this led to the
-- standard Gradient|Hessian|Jacobian functions.
--standardJacobian: (Vector(F),List(S)) -> Matrix F
-- ++ \spad{jacobian(vf,xlist)}
-- ++ computes the jacobian, the matrix of first partial derivatives,
-- ++ of the vector field vf,
-- ++ vf a vector function of the variables listed in xlist.
jacobian: (FLAF,FLAS) -> Matrix F
++ \spad{jacobian(vf,xlist)}
++ computes the jacobian, the matrix of first partial derivatives,
++ of the vector field vf,
++ vf a vector function of the variables listed in xlist.
```

```

bandedJacobian: (FLAF,FLAS,NNI,NNI) -> Matrix F
++ \spad{bandedJacobian(vf,xlist,kl,ku)}
++ computes the jacobian, the matrix of first partial derivatives,
++ of the vector field vf,
++ vf a vector function of the variables listed in xlist,
++ kl is the number of nonzero subdiagonals,
++ ku is the number of nonzero superdiagonals,
++ kl+ku+1 being actual bandwidth.
++ Stores the nonzero band in a matrix,
++ dimensions kl+ku+1 by #xlist.
++ The upper triangle is in the top ku rows,
++ the diagonal is in row ku+1,
++ the lower triangle in the last kl rows.
++ Entries in a column in the band store correspond to entries
++ in same column of full store.
++ (The notation conforms to LAPACK/NAG-F07 conventions.)

```

```

                                Eigenvalues and Eigenvectors
```

1. Scope of the Chapter

This chapter is concerned with computing

- eigenvalues and eigenvectors of a matrix
- eigenvalues and eigenvectors of generalized matrix
eigenvalue problems
- singular values and singular vectors of a matrix.

2. Background to the Problems

2.1. Eigenvalue Problems

In the most usual form of eigenvalue problem we are given a square n by n matrix A and wish to compute (λ) (an eigenvalue) and $x \neq 0$ (an eigenvector) which satisfy the equation

$$Ax = (\lambda)x$$

Such problems are called 'standard' eigenvalue problems in contrast to 'generalized' eigenvalue problems where we wish to satisfy the equation

$$Ax = (\lambda)Bx$$

B also being a square n by n matrix.

Section 2.1.1 and Section 2.1.2 discuss, respectively, standard and generalized eigenvalue problems where the matrices involved are dense; Section 2.1.3 discusses both types of problem in the case where A and B are sparse (and symmetric).

2.1.1. Standard eigenvalue problems

Some of the routines in this chapter find all the n eigenvalues, some find all the n eigensolutions (eigenvalues and corresponding eigenvectors), and some find a selected group of eigenvalues and/or eigenvectors. The matrix A may be:

- (i) general (real or complex)
- (ii) real symmetric, or
- (iii) complex Hermitian (so that if $a_{ij} = (\alpha) + i(\beta)$ then $a_{ji} = (\alpha) - i(\beta)$).

In all cases the computation starts with a similarity

$$S^{-1}AS = T,$$

where S is non-singular and is the product of fairly simple matrices, and T has an 'easier form' than A so that its eigensolutions are easily determined. The matrices A and T, of course, have the same eigenvalues, and if y is an eigenvector of T then Sy is the corresponding eigenvector of A.

In case (i) (general real or complex A), the selected form of T is an upper Hessenberg matrix ($t_{ij} = 0$ if $i-j > 1$) and S is the

$$S = \begin{pmatrix} s_{11} & s_{12} & \dots & s_{1n} \\ s_{21} & s_{22} & \dots & s_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ s_{n1} & s_{n2} & \dots & s_{nn} \end{pmatrix}$$

product of $n-2$ stabilised elementary transformation matrices. There is no easy method of computing selected eigenvalues of a Hessenberg matrix, so that all eigenvalues are always calculated. In the real case this computation is performed via the Francis QR algorithm with double shifts, and in the complex case by means of

the LR algorithm. If the eigenvectors are required they are computed by back-substitution following the QR and LR algorithm.

In case (ii) (real and symmetric A) the selected simple form of T is a tridiagonal matrix ($t_{ij} = 0$ if $|i-j| > 1$), and S is the product

\prod_{ij}

of $n-2$ orthogonal Householder transformation matrices. If only selected eigenvalues are required, they are obtained by the method of bisection using the Sturm sequence property, and the corresponding eigenvectors of T are computed by inverse iteration. If all eigenvalues are required, they are computed from T via the QL algorithm (an adaptation of the QR algorithm), and the corresponding eigenvectors of T are the product of the transformations for the QL reduction. In all cases the corresponding eigenvectors of A are recovered from the computation of $x = Sy$.

In case (iii) (complex Hermitian A) analogous transformations as in case (ii) are used. T has complex elements in off-diagonal positions, but a simple diagonal similarity transformation is then used to produce a real tridiagonal form, after which the QL algorithm and succeeding methods described in the previous paragraph are used to complete the solution.

2.1.2. Generalized eigenvalue problems

Here we distinguish as a special case those problems in which both A and B are symmetric and B is positive-definite and well-conditioned with respect to inversion (i.e., all the eigenvalues of B are significantly greater than zero). Such problems can be satisfactorily treated by first reducing them to case (ii) of Section 2.1.1 and then using the methods described there to

T

compute the eigensolutions. If B is factorized as LL^T (L lower triangular), then $Ax = (\lambda)Bx$ is equivalent to the standard

$-1 \quad T \quad -1 \quad T$

symmetric problem $Ry = (\lambda)y$, where $R = L^T A(L)^{-1}$ and $y = L^T x$. After finding an eigenvector y of R, the required x is computed

T

by back-substitution in $y = L^T x$.

For generalized problems of the form $Ax = (\lambda)Bx$ which do not fall into the special case, the QZ algorithm is provided.

In order to appreciate the domain in which this algorithm is appropriate we remark first that when B is non-singular the

problem $Ax = (\lambda)Bx$ is fully equivalent to the problem

$(B^{-1}A)x = (\lambda)x$; both the eigenvalues and eigenvectors being the same. When A is non-singular $Ax = (\lambda)Bx$ is equivalent to

the problem $(A^{-1}B)x = (\mu)x$; the eigenvalues (μ) being the reciprocals of the required eigenvalues and the eigenvectors remaining the same. In theory then, provided at least one of the matrices A and B is non-singular, the generalized problem $Ax = (\lambda)Bx$ could be solved via the standard problem $Cx = (\lambda)x$ with an appropriate matrix C , and as far as economy of effort is concerned this is quite satisfactory. However, in practice, for this reduction to be satisfactory from the standpoint of numerical stability, one requires more than the

mere non-singularity of A or B . It is necessary that $B^{-1}A$ (or $A^{-1}B$) should not only exist but that B (or A) should be well-conditioned with respect to inversion. The nearer B (or A) is to

singularity the more unsatisfactory $B^{-1}A$ (or $A^{-1}B$) will be as a vehicle for determining the required eigenvalues. Unfortunately one cannot counter ill-conditioning in B (or A) by computing $B^{-1}A$

(or $A^{-1}B$) accurately to single precision using iterative refinement. Well-determined eigenvalues of the original $Ax = (\lambda)Bx$ may be poorly determined even by the correctly

rounded version of $B^{-1}A$ (or $A^{-1}B$). The situation may in some instances be saved by the observation that if $Ax = (\lambda)Bx$ then $(A - kB)x = ((\lambda) - k)Bx$. Hence if $A - kB$ is non-singular we may

solve the standard problem $[(A - kB)B^{-1}]x = (\mu)x$ and for numerical stability we require only that $(A - kB)$ be well-conditioned with respect to inversion.

In practice one may well be in a situation where no k is known for which $(A - kB)$ is well-conditioned with respect to inversion and indeed $(A - kB)$ may be singular for all k . The QZ algorithm is designed to deal directly with the problem $Ax = (\lambda)Bx$ itself and its performance is unaffected by singularity or near-singularity of A , B or $A - kB$.

2.1.3. Sparse symmetric problems

If the matrices A and B are large and sparse (i.e., only a small proportion of the elements are non-zero), then the methods described in the previous Section are unsuitable, because in reducing the problem to a simpler form, much of the sparsity of the problem would be lost; hence the computing time and the storage required would be very large. Instead, for symmetric problems, the method of simultaneous iteration may be used to determine selected eigenvalues and the corresponding eigenvectors. The routine provided has been designed to handle both symmetric and generalized symmetric problems.

2.2. Singular Value Problems

The singular value decomposition of an m by n real matrix A is given by

$$A = QDP^T,$$

where Q is an m by m orthogonal matrix, P is an n by n orthogonal matrix and D is an m by n diagonal matrix with non-negative diagonal elements. The first $k = \min(m, n)$ columns of Q and P are the left- and right-hand singular vectors of A and the k diagonal elements of D are the singular values.

When A is complex then the singular value decomposition is given by

$$A = QDP^H,$$

where Q and P are unitary, P^H denotes the complex conjugate of P and D is as above for the real case.

If the matrix A has column means of zero, then AP is the matrix of principal components of A and the singular values are the square roots of the sample variances of the observations with respect to the principal components. (See also Chapter G03.)

Routines are provided to return the singular values and vectors of a general real or complex matrix.

3. Recommendations on Choice and Use of Routines

3.1. General Discussion

There is one routine, F02FJF, which is designed for sparse symmetric eigenvalue problems, either standard or generalized. The remainder of the routines are designed for dense matrices.

3.2. Eigenvalue and Eigenvector Routines

These reduce the matrix A to a simpler form by a similarity transformation $S^{-1}AS=T$ where T is an upper Hessenberg or tridiagonal matrix, compute the eigensolutions of T , and then recover the eigenvectors of A via the matrix S . The eigenvectors are normalised so that

$$\sum_{r=1}^n |x_r|^2 = 1$$

x_r being the r th component of the eigenvector x , and so that the element of largest modulus is real if x is complex. For problems of the type $Ax=(\lambda)Bx$ with A and B symmetric and B positive-definite, the eigenvectors are normalised so that $x^T Bx=1$, x always being real for such problems.

3.3. Singular Value and Singular Vector Routines

These reduce the matrix A to real bidiagonal form, B say, by orthogonal transformations $Q^T A P=B$ in the real case, and by unitary transformations $Q^H A P=B$ in the complex case, and the singular values and vectors are computed via this bidiagonal form. The singular values are returned in descending order.

3.4. Decision Trees

(i) Eigenvalues and Eigenvectors

F02 -- Eigenvalue and Eigenvectors F02AAF
 F02AAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AAF calculates all the eigenvalues of a real symmetric matrix.

2. Specification

```
SUBROUTINE F02AAF (A, IA, N, R, E, IFAIL)
  INTEGER          IA, N, IFAIL
  DOUBLE PRECISION A(IA,N), R(N), E(N)
```

3. Description

This routine reduces the real symmetric matrix A to a real symmetric tridiagonal matrix using Householder's method. The eigenvalues of the tridiagonal matrix are then determined using the QL algorithm.

4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

- 1: A(IA,N) -- DOUBLE PRECISION array Input/Output
 On entry: the lower triangle of the n by n symmetric matrix A. The elements of the array above the diagonal need not be set. On exit: the elements of A below the diagonal are overwritten, and the rest of the array is unchanged.
- 2: IA -- INTEGER Input
 On entry:
 the first dimension of the array A as declared in the (sub)program from which F02AAF is called.
 Constraint: IA >= N.

- 3: N -- INTEGER Input
 On entry: n, the order of the matrix A.
- 4: R(N) -- DOUBLE PRECISION array Output
 On exit: the eigenvalues in ascending order.
- 5: E(N) -- DOUBLE PRECISION array Workspace
- 6: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
 Failure in F02AVF(*) indicating that more than 30*N iterations are required to isolate all the eigenvalues.

7. Accuracy

The accuracy of the eigenvalues depends on the sensitivity of the matrix to rounding errors produced in tridiagonalisation. For a detailed error analysis see Wilkinson and Reinsch [1] pp 222 and 235.

8. Further Comments

3

The time taken by the routine is approximately proportional to n

9. Example

To calculate all the eigenvalues of the real symmetric matrix:

```
( 0.5  0.0  2.3 -2.6)
( 0.0  0.5 -1.4 -0.7)
( 2.3 -1.4  0.5  0.0).
(-2.6 -0.7  0.0  0.5)
```

The example program is not reproduced here. The source code for

all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F02 -- Eigenvalue and Eigenvectors F02ABF
 F02ABF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02ABF calculates all the eigenvalues and eigenvectors of a real symmetric matrix.

2. Specification

```
SUBROUTINE F02ABF (A, IA, N, R, V, IV, E, IFAIL)
  INTEGER          IA, N, IV, IFAIL
  DOUBLE PRECISION A(IA,N), R(N), V(IV,N), E(N)
```

3. Description

This routine reduces the real symmetric matrix A to a real symmetric tridiagonal matrix by Householder's method. The eigenvalues and eigenvectors are calculated using the QL algorithm.

4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

- 1: A(IA,N) -- DOUBLE PRECISION array Input
 On entry: the lower triangle of the n by n symmetric matrix A. The elements of the array above the diagonal need not be set. See also Section 8.
- 2: IA -- INTEGER Input
 On entry:
 the first dimension of the array A as declared in the

(sub)program from which F02ABF is called.
 Constraint: $IA \geq N$.

- | | | |
|----|---|--------------|
| 3: | N -- INTEGER | Input |
| | On entry: n, the order of the matrix A. | |
| 4: | R(N) -- DOUBLE PRECISION array | Output |
| | On exit: the eigenvalues in ascending order. | |
| 5: | V(IV,N) -- DOUBLE PRECISION array | Output |
| | On exit: the normalised eigenvectors, stored by columns;
the ith column corresponds to the ith eigenvalue. The
eigenvectors are normalised so that the sum of squares of
the elements is equal to 1. | |
| 6: | IV -- INTEGER | Input |
| | On entry:
the first dimension of the array V as declared in the
(sub)program from which F02ABF is called.
Constraint: $IV \geq N$. | |
| 7: | E(N) -- DOUBLE PRECISION array | Workspace |
| 8: | IFAIL -- INTEGER | Input/Output |
| | On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0. | |
| | On exit: IFAIL = 0 unless the routine detects an error (see
Section 6). | |

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

Failure in F02AMF(*) indicating that more than $30 \times N$
 iterations are required to isolate all the eigenvalues.

7. Accuracy

The eigenvectors are always accurately orthogonal but the accuracy of the individual eigenvectors is dependent on their inherent sensitivity to changes in the original matrix. For a detailed error analysis see Wilkinson and Reinsch [1] pp 222 and 235.

8. Further Comments

3

The time taken by the routine is approximately proportional to n

Unless otherwise stated in the Users' Note for your implementation, the routine may be called with the same actual array supplied for parameters A and V, in which case the eigenvectors will overwrite the original matrix. However this is not standard Fortran 77, and may not work on all systems.

9. Example

To calculate all the eigenvalues and eigenvectors of the real symmetric matrix:

```
( 0.5  0.0  2.3 -2.6)
( 0.0  0.5 -1.4 -0.7)
( 2.3 -1.4  0.5  0.0).
(-2.6 -0.7  0.0  0.5)
```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F02 -- Eigenvalue and Eigenvectors

F02ADF

F02ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02ADF calculates all the eigenvalues of $Ax=(\lambda)Bx$, where A is a real symmetric matrix and B is a real symmetric positive-definite matrix.

2. Specification

```
SUBROUTINE F02ADF (A, IA, B, IB, N, R, DE, IFAIL)
INTEGER           IA, IB, N, IFAIL
```

DOUBLE PRECISION A(IA,N), B(IB,N), R(N), DE(N)

3. Description

The problem is reduced to the standard symmetric eigenproblem using Cholesky's method to decompose B into triangular matrices,

$B = LL^T$, where L is lower triangular. Then $Ax = (\lambda)Bx$ implies
 $(L^{-1}AL^{-T})(Lx) = (\lambda)(Lx)$; hence the eigenvalues of
 $Ax = (\lambda)Bx$ are those of $Py = (\lambda)y$ where P is the symmetric
 $L^{-1}AL^{-T}$ matrix. Householder's method is used to tridiagonalise
 the matrix P and the eigenvalues are then found using the QL
 algorithm.

4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

- 1: A(IA,N) -- DOUBLE PRECISION array Input/Output
 On entry: the upper triangle of the n by n symmetric matrix A. The elements of the array below the diagonal need not be set. On exit: the lower triangle of the array is overwritten. The rest of the array is unchanged.
- 2: IA -- INTEGER Input
 On entry:
 the first dimension of the array A as declared in the (sub)program from which F02ADF is called.
 Constraint: IA >= N.
- 3: B(IB,N) -- DOUBLE PRECISION array Input/Output
 On entry: the upper triangle of the n by n symmetric positive-definite matrix B. The elements of the array below the diagonal need not be set. On exit: the elements below the diagonal are overwritten. The rest of the array is unchanged.
- 4: IB -- INTEGER Input
 On entry:
 the first dimension of the array B as declared in the (sub)program from which F02ADF is called.

Constraint: $IB \geq N$.

- | | | |
|----|---|--------------|
| 5: | N -- INTEGER | Input |
| | On entry: n, the order of the matrices A and B. | |
| 6: | R(N) -- DOUBLE PRECISION array | Output |
| | On exit: the eigenvalues in ascending order. | |
| 7: | DE(N) -- DOUBLE PRECISION array | Workspace |
| 8: | IFAIL -- INTEGER | Input/Output |
| | On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0. | |
| | On exit: IFAIL = 0 unless the routine detects an error (see Section 6). | |

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

Failure in F01AEF(*); the matrix B is not positive-definite possibly due to rounding errors.

IFAIL= 2

Failure in F02AVF(*), more than $30 \cdot N$ iterations are required to isolate all the eigenvalues.

7. Accuracy

In general this routine is very accurate. However, if B is ill-conditioned with respect to inversion, the eigenvalues could be inaccurately determined. For a detailed error analysis see Wilkinson and Reinsch [1] pp 310, 222 and 235.

8. Further Comments

3

The time taken by the routine is approximately proportional to n

9. Example

To calculate all the eigenvalues of the general symmetric eigenproblem $Ax = (\lambda B) Bx$ where A is the symmetric matrix:

```

(0.5  1.5  6.6  4.8)
(1.5  6.5 16.2  8.6)
(6.6 16.2 37.6  9.8)
(4.8  8.6  9.8 -17.1)

```

and B is the symmetric positive-definite matrix:

```

(1  3  4  1)
(3 13 16 11)
(4 16 24 18).
(1 11 18 27)

```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F02 -- Eigenvalue and Eigenvectors                                F02AEF
      F02AEF -- NAG Foundation Library Routine Document

```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AEF calculates all the eigenvalues and eigenvectors of $Ax=(\lambda)Bx$, where A is a real symmetric matrix and B is a real symmetric positive-definite matrix.

2. Specification

```

      SUBROUTINE F02AEF (A, IA, B, IB, N, R, V, IV, DL, E, IFAIL)
      INTEGER           IA, IB, N, IV, IFAIL
      DOUBLE PRECISION A(IA,N), B(IB,N), R(N), V(IV,N), DL(N), E
1                      (N)

```

3. Description

The problem is reduced to the standard symmetric eigenproblem using Cholesky's method to decompose B into triangular matrices

$B=LL^T$, where L is lower triangular. Then $Ax=(\lambda)Bx$ implies

$(L - \lambda I)^{-1} (L - \lambda I)^T x = (\lambda - \lambda) (L - \lambda I)^T x$; hence the eigenvalues of $Ax = (\lambda - \lambda)Bx$ are those of $Py = (\lambda - \lambda)y$, where P is the symmetric matrix $L - \lambda I$. Householder's method is used to tridiagonalise the matrix P and the eigenvalues are found using the QL algorithm. An eigenvector z of the derived problem is related to an eigenvector x of the original problem by $z = L^{-1} x$. The eigenvectors z are determined using the QL algorithm and are normalised so that $z^T z = 1$; the eigenvectors of the original problem are then determined by solving $L x = z$, and are normalised so that $x^T B x = 1$.

4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

- 1: A(IA,N) -- DOUBLE PRECISION array Input/Output
 On entry: the upper triangle of the n by n symmetric matrix A. The elements of the array below the diagonal need not be set. On exit: the lower triangle of the array is overwritten. The rest of the array is unchanged. See also Section 8.
- 2: IA -- INTEGER Input
 On entry:
 the first dimension of the array A as declared in the (sub)program from which F02AEF is called.
 Constraint: IA >= N.
- 3: B(IB,N) -- DOUBLE PRECISION array Input/Output
 On entry: the upper triangle of the n by n symmetric positive-definite matrix B. The elements of the array below the diagonal need not be set. On exit: the elements below the diagonal are overwritten. The rest of the array is unchanged.
- 4: IB -- INTEGER Input

On entry:
the first dimension of the array B as declared in the
(sub)program from which F02AEF is called.
Constraint: IB \geq N.

- 5: N -- INTEGER Input
On entry: n, the order of the matrices A and B.
- 6: R(N) -- DOUBLE PRECISION array Output
On exit: the eigenvalues in ascending order.
- 7: V(IV,N) -- DOUBLE PRECISION array Output
On exit: the normalised eigenvectors, stored by columns;
the ith column corresponds to the ith eigenvalue. The
T
eigenvectors x are normalised so that $x^T B x = 1$. See also
Section 8.
- 8: IV -- INTEGER Input
On entry:
the first dimension of the array V as declared in the
(sub)program from which F02AEF is called.
Constraint: IV \geq N.
- 9: DL(N) -- DOUBLE PRECISION array Workspace
- 10: E(N) -- DOUBLE PRECISION array Workspace
- 11: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.
On exit: IFAIL = 0 unless the routine detects an error (see
Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

Failure in F01AEF(*); the matrix B is not positive-definite,
possibly due to rounding errors.

IFAIL= 2

Failure in F02AMF(*); more than 30*N iterations are required
to isolate all the eigenvalues.

7. Accuracy

In general this routine is very accurate. However, if B is ill-conditioned with respect to inversion, the eigenvectors could be inaccurately determined. For a detailed error analysis see Wilkinson and Reinsch [1] pp 310, 222 and 235.

8. Further Comments

The time taken by the routine is approximately proportional to n^3

Unless otherwise stated in the Users' Note for your implementation, the routine may be called with the same actual array supplied for parameters A and V, in which case the eigenvectors will overwrite the original matrix A. However this is not standard Fortran 77, and may not work on all systems.

9. Example

To calculate all the eigenvalues and eigenvectors of the general symmetric eigenproblem $Ax = (\lambda) Bx$ where A is the symmetric matrix:

```
(0.5  1.5  6.6  4.8)
(1.5  6.5 16.2  8.6)
(6.6 16.2 37.6  9.8)
(4.8  8.6  9.8 -17.1)
```

and B is the symmetric positive-definite matrix:

```
(1  3  4  1)
(3 13 16 11)
(4 16 24 18).
(1 11 18 27)
```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F02AFF

F02AFF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AFF calculates all the eigenvalues of a real unsymmetric matrix.

2. Specification

```
SUBROUTINE F02AFF (A, IA, N, RR, RI, INTGER, IFAIL)
  INTEGER          IA, N, INTGER(N), IFAIL
  DOUBLE PRECISION A(IA,N), RR(N), RI(N)
```

3. Description

The matrix A is first balanced and then reduced to upper Hessenberg form using stabilised elementary similarity transformations. The eigenvalues are then found using the QR algorithm for real Hessenberg matrices.

4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

- 1: A(IA,N) -- DOUBLE PRECISION array Input/Output
On entry: the n by n matrix A. On exit: the array is overwritten.
- 2: IA -- INTEGER Input
On entry:
the dimension of the array A as declared in the (sub)program from which F02AFF is called.
Constraint: IA >= N.
- 3: N -- INTEGER Input
On entry: n, the order of the matrix A.
- 4: RR(N) -- DOUBLE PRECISION array Output
On exit: the real parts of the eigenvalues.

5: RI(N) -- DOUBLE PRECISION array Output
 On exit: the imaginary parts of the eigenvalues.

6: INTGER(N) -- INTEGER array Output
 On exit: INTGER(i) contains the number of iterations used to find the ith eigenvalue. If INTGER(i) is negative, the ith eigenvalue is the second of a pair found simultaneously.

Note that the eigenvalues are found in reverse order, starting with the nth.

7: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

More than 30*N iterations are required to isolate all the eigenvalues.

7. Accuracy

The accuracy of the results depends on the original matrix and the multiplicity of the roots. For a detailed error analysis see Wilkinson and Reinsch [1] pp 352 and 367.

8. Further Comments

3

The time taken by the routine is approximately proportional to n

9. Example

To calculate all the eigenvalues of the real matrix:

```
( 1.5 0.1  4.5 -1.5)
(-22.5 3.5 12.5 -2.5)
( -2.5 0.3  4.5 -2.5).
( -2.5 0.1  4.5  2.5)
```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F02 -- Eigenvalue and Eigenvectors F02AGF
 F02AGF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AGF calculates all the eigenvalues and eigenvectors of a real unsymmetric matrix.

2. Specification

```

      SUBROUTINE F02AGF (A, IA, N, RR, RI, VR, IVR, VI, IVI,
1      INTEGER, IFAIL)
      INTEGER          IA, N, IVR, IVI, INTGER(N), IFAIL
      DOUBLE PRECISION A(IA,N), RR(N), RI(N), VR(IVR,N), VI
1      (IVI,N)

```

3. Description

The matrix A is first balanced and then reduced to upper Hessenberg form using real stabilised elementary similarity transformations. The eigenvalues and eigenvectors of the Hessenberg matrix are calculated using the QR algorithm. The eigenvectors of the Hessenberg matrix are back-transformed to give the eigenvectors of the original matrix A.

4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

- 1: A(IA,N) -- DOUBLE PRECISION array Input/Output
 On entry: the n by n matrix A. On exit: the array is

overwritten.

- 2: IA -- INTEGER Input
 On entry:
 the first dimension of the array A as declared in the
 (sub)program from which F02AGF is called.
 Constraint: IA \geq N.

- 3: N -- INTEGER Input
 On entry: n, the order of the matrix A.

- 4: RR(N) -- DOUBLE PRECISION array Output
 On exit: the real parts of the eigenvalues.

- 5: RI(N) -- DOUBLE PRECISION array Output
 On exit: the imaginary parts of the eigenvalues.

- 6: VR(IVR,N) -- DOUBLE PRECISION array Output
 On exit: the real parts of the eigenvectors, stored by
 columns. The ith column corresponds to the ith eigenvalue.
 The eigenvectors are normalised so that the sum of the
 squares of the moduli of the elements is equal to 1 and the
 element of largest modulus is real. This ensures that real
 eigenvalues have real eigenvectors.

- 7: IVR -- INTEGER Input
 On entry:
 the first dimension of the array VR as declared in the
 (sub)program from which F02AGF is called.
 Constraint: IVR \geq N.

- 8: VI(IVI,N) -- DOUBLE PRECISION array Output
 On exit: the imaginary parts of the eigenvectors, stored by
 columns. The ith column corresponds to the ith eigenvalue.

- 9: IVI -- INTEGER Input
 On entry:
 the first dimension of the array VI as declared in the
 (sub)program from which F02AGF is called.
 Constraint: IVI \geq N.

- 10: INTGER(N) -- INTEGER array Output
 On exit: INTGER(i) contains the number of iterations used
 to find the ith eigenvalue. If INTGER(i) is negative, the i
 th eigenvalue is the second of a pair found simultaneously.

```

11:  IFAIL -- INTEGER                                Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not
familiar with this parameter (described in the Essential
Introduction) the recommended value is 0.

```

6. Error Indicators and Warnings

IFAIL= 1

7. Accuracy

8. Further Comments

9. Example

$$\begin{pmatrix} 1.5 & 0.1 & 4.5 & -1.5 \\ -22.5 & 3.5 & 12.5 & -2.5 \\ -2.5 & 0.3 & 4.5 & -2.5 \\ -2.5 & 0.1 & 4.5 & 2.5 \end{pmatrix}$$
[illegible]

F02 -- Eigenvalue and Eigenvectors F02AJF
 F02AJF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AJF calculates all the eigenvalues of a complex matrix.

2. Specification

```

      SUBROUTINE F02AJF (AR, IAR, AI, IAI, N, RR, RI, INTGER,
1      IFAIL)
      INTEGER          IAR, IAI, N, INTGER(N), IFAIL
      DOUBLE PRECISION AR(IAR,N), AI(IAI,N), RR(N), RI(N)

```

3. Description

The complex matrix A is first balanced and then reduced to upper Hessenberg form using stabilised elementary similarity transformations. The eigenvalues are then found using the modified LR algorithm for complex Hessenberg matrices.

4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

- 1: AR(IAR,N) -- DOUBLE PRECISION array Input/Output
 On entry: the real parts of the elements of the n by n complex matrix A. On exit: the array is overwritten.
- 2: IAR -- INTEGER Input
 On entry:
 the first dimension of the array AR as declared in the (sub)program from which F02AJF is called.
 Constraint: IAR >= N.
- 3: AI(IAI,N) -- DOUBLE PRECISION array Input/Output
 On entry: the imaginary parts of the elements of the n by n complex matrix A. On exit: the array is overwritten.

- 4: IAI -- INTEGER Input
 On entry:
 the first dimension of the array AI as declared in the
 (sub)program from which F02AJF is called.
 Constraint: IAI \geq N.
- 5: N -- INTEGER Input
 On entry: n, the order of the matrix A.
- 6: RR(N) -- DOUBLE PRECISION array Output
 On exit: the real parts of the eigenvalues.
- 7: RI(N) -- DOUBLE PRECISION array Output
 On exit: the imaginary parts of the eigenvalues.
- 8: INTGER(N) -- INTEGER array Workspace
- 9: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not
 familiar with this parameter (described in the Essential
 Introduction) the recommended value is 0.

 On exit: IFAIL = 0 unless the routine detects an error (see
 Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
 More than 30*N iterations are required to isolate all the
 eigenvalues.

7. Accuracy

The accuracy of the results depends on the original matrix and
 the multiplicity of the roots. For a detailed error analysis see
 Wilkinson and Reinsch [1] pp 352 and 401.

8. Further Comments

3

The time taken by the routine is approximately proportional to n

9. Example

To calculate all the eigenvalues of the complex matrix:

```
(-21.0-5.0i      24.60i 13.6+10.2i      4.0i)
(      22.5i 26.00-5.00i  7.5-10.0i 2.5      )
( -2.0+1.5i  1.68+2.24i  4.5-5.0i  1.5+2.0i).
(      -2.5i -2.60      -2.7+3.6i  2.5-5.0i)
```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F02 -- Eigenvalue and Eigenvectors F02AWF
 F02AWF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AWF calculates all the eigenvalues of a complex Hermitian matrix.

2. Specification

```

      SUBROUTINE F02AWF (AR, IAR, AI, IAI, N, R, WK1, WK2, WK3,
1                      IFAIL)
      INTEGER          IAR, IAI, N, IFAIL
      DOUBLE PRECISION AR(IAR,N), AI(IAI,N), R(N), WK1(N),
1                      WK2(N), WK3(N)

```

3. Description

The complex Hermitian matrix A is first reduced to a real tridiagonal matrix by n-2 unitary transformations, and a subsequent diagonal transformation. The eigenvalues are then derived using the QL algorithm, an adaptation of the QR algorithm.

4. References

- [1] Peters G (1967) NPL Algorithms Library. Document No. F1/04/A.
- [2] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

- 1: AR(IAR,N) -- DOUBLE PRECISION array Input/Output
 On entry: the real parts of the elements of the lower triangle of the n by n complex Hermitian matrix A. Elements of the array above the diagonal need not be set. On exit: the array is overwritten.

- 2: IAR -- INTEGER Input
 On entry:
 the first dimension of the array AR as declared in the (sub)program from which F02AWF is called.
 Constraint: IAR \geq N.

- 3: AI(IAI,N) -- DOUBLE PRECISION array Input/Output
 On entry: the imaginary parts of the elements of the lower triangle of the n by n complex Hermitian matrix A. Elements of the array above the diagonal need not be set. On exit: the array is overwritten.

- 4: IAI -- INTEGER Input
 On entry:
 the first dimension of the array AI as declared in the (sub)program from which F02AWF is called.
 Constraint: IAI \geq N.

- 5: N -- INTEGER Input
 On entry: n, the order of the complex Hermitian matrix, A.

- 6: R(N) -- DOUBLE PRECISION array Output
 On exit: the eigenvalues in ascending order.

- 7: WK1(N) -- DOUBLE PRECISION array Workspace

- 8: WK2(N) -- DOUBLE PRECISION array Workspace

- 9: WK3(N) -- DOUBLE PRECISION array Workspace

- 10: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

More than 30*N iterations are required to isolate all the eigenvalues.

7. Accuracy

For a detailed error analysis see Peters [1] page 3 and Wilkinson and Reinsch [2] page 235.

8. Further Comments

3

The time taken by the routine is approximately proportional to n^3

9. Example

To calculate all the eigenvalues of the complex Hermitian matrix:

(0.50	0.00	1.84+1.38i	2.08-1.56i)
(0.00	0.50	1.12+0.84i	-0.56+0.42i)
(1.84-1.38i	1.12-0.84i	0.50	0.00)
(2.08+1.56i	-0.56-0.42i	0.00	0.50)

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F02 -- Eigenvalue and Eigenvectors

F02AXF

F02AXF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02AXF calculates all the eigenvalues and eigenvectors of a complex Hermitian matrix.

2. Specification

```

      SUBROUTINE F02AXF (AR, IAR, AI, IAI, N, R, VR, IVR, VI,
1          IVI, WK1, WK2, WK3, IFAIL)
      INTEGER          IAR, IAI, N, IVR, IVI, IFAIL
      DOUBLE PRECISION AR(IAR,N), AI(IAI,N), R(N), VR(IVR,N), VI
1          (IVI,N), WK1(N), WK2(N), WK3(N)

```

3. Description

The complex Hermitian matrix is first reduced to a real tridiagonal matrix by $n-2$ unitary transformations and a subsequent diagonal transformation. The eigenvalues and eigenvectors are then derived using the QL algorithm, an adaptation of the QR algorithm.

4. References

- [1] Peters G (1967) NPL Algorithms Library. Document No. F2/03/A.
- [2] Peters G (1967) NPL Algorithms Library. Document No. F1/04/A.

5. Parameters

- 1: AR(IAR,N) -- DOUBLE PRECISION array Input
 On entry: the real parts of the elements of the lower triangle of the n by n complex Hermitian matrix A . Elements of the array above the diagonal need not be set. See also Section 8.
- 2: IAR -- INTEGER Input
 On entry:
 the first dimension of the array AR as declared in the (sub)program from which F02AXF is called.
 Constraint: IAR \geq N.
- 3: AI(IAI,N) -- DOUBLE PRECISION array Input
 On entry: the imaginary parts of the elements of the lower triangle of the n by n complex Hermitian matrix A . Elements of the array above the diagonal need not be set. See also Section 8.
- 4: IAI -- INTEGER Input

On entry:
the first dimension of the array AI as declared in the
(sub)program from which F02AXF is called.
Constraint: IAI \geq N.

- | | | |
|-----|---|--------------|
| 5: | N -- INTEGER | Input |
| | On entry: n, the order of the matrix, A. | |
| 6: | R(N) -- DOUBLE PRECISION array | Output |
| | On exit: the eigenvalues in ascending order. | |
| 7: | VR(IVR,N) -- DOUBLE PRECISION array | Output |
| | On exit: the real parts of the eigenvectors, stored by columns. The ith column corresponds to the ith eigenvector. The eigenvectors are normalised so that the sum of the squares of the moduli of the elements is equal to 1 and the element of largest modulus is real. See also Section 8. | |
| 8: | IVR -- INTEGER | Input |
| | On entry:
the first dimension of the array VR as declared in the
(sub)program from which F02AXF is called.
Constraint: IVR \geq N. | |
| 9: | VI(IVI,N) -- DOUBLE PRECISION array | Output |
| | On exit: the imaginary parts of the eigenvectors, stored by columns. The ith column corresponds to the ith eigenvector. See also Section 8. | |
| 10: | IVI -- INTEGER | Input |
| | On entry:
the first dimension of the array VI as declared in the
(sub)program from which F02AXF is called.
Constraint: IVI \geq N. | |
| 11: | WK1(N) -- DOUBLE PRECISION array | Workspace |
| 12: | WK2(N) -- DOUBLE PRECISION array | Workspace |
| 13: | WK3(N) -- DOUBLE PRECISION array | Workspace |
| 14: | IFAIL -- INTEGER | Input/Output |
| | On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0. | |

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

More than 30*N iterations are required to isolate all the eigenvalues.

IFAIL= 2

The diagonal elements of AI are not all zero, i.e., the complex matrix is not Hermitian.

7. Accuracy

The eigenvectors are always accurately orthogonal but the accuracy of the individual eigenvalues and eigenvectors is dependent on their inherent sensitivity to small changes in the original matrix. For a detailed error analysis see Peters [1] page 3 and [2] page 3.

8. Further Comments

3

The time taken by the routine is approximately proportional to n

Unless otherwise stated in the implementation document, the routine may be called with the same actual array supplied for parameters AR and VR, and for AI and VI, in which case the eigenvectors will overwrite the original matrix A. However this is not standard Fortran 77, and may not work on all systems.

9. Example

To calculate the eigenvalues and eigenvectors of the complex Hermitian matrix:

(0.50	0.00	1.84+1.38i	2.08-1.56i)
(0.00	0.50	1.12+0.84i	-0.56+0.42i)
(1.84-1.38i	1.12-0.84i	0.50	0.00)
(2.08+1.56i	-0.56-0.42i	0.00	0.50)

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation

Library software and should be available on-line.

F02 -- Eigenvalue and Eigenvectors F02BBF
 F02BBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02BBF calculates selected eigenvalues and eigenvectors of a real symmetric matrix by reduction to tridiagonal form, bisection and inverse iteration, where the selected eigenvalues lie within a given interval.

2. Specification

```

      SUBROUTINE F02BBF (A, IA, N, ALB, UB, M, MM, R, V, IV, D,
1      E, E2, X, G, C, ICOUNT, IFAIL)
      INTEGER          IA, N, M, MM, IV, ICOUNT(M), IFAIL
      DOUBLE PRECISION A(IA,N), ALB, UB, R(M), V(IV,M), D(N), E
1      (N), E2(N), X(N,7), G(N)
      LOGICAL          C(N)

```

3. Description

The real symmetric matrix A is reduced to a symmetric tridiagonal matrix T by Householder's method. The eigenvalues which lie within a given interval [l,u], are calculated by the method of bisection. The corresponding eigenvectors of T are calculated by inverse iteration. A back-transformation is then performed to obtain the eigenvectors of the original matrix A.

4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

- 1: A(IA,N) -- DOUBLE PRECISION array Input/Output
 On entry: the lower triangle of the n by n symmetric matrix

A. The elements of the array above the diagonal need not be set. On exit: the elements of A below the diagonal are overwritten, and the rest of the array is unchanged.

- | | | |
|-----|--|-----------|
| 2: | IA -- INTEGER | Input |
| | On entry: | |
| | the first dimension of the array A as declared in the | |
| | (sub)program from which F02BBF is called. | |
| | Constraint: IA >= N. | |
| 3: | N -- INTEGER | Input |
| | On entry: n, the order of the matrix A. | |
| 4: | ALB -- DOUBLE PRECISION | Input |
| 5: | UB -- DOUBLE PRECISION | Input |
| | On entry: l and u, the lower and upper end-points of the | |
| | interval within which eigenvalues are to be calculated. | |
| 6: | M -- INTEGER | Input |
| | On entry: an upper bound for the number of eigenvalues | |
| | within the interval. | |
| 7: | MM -- INTEGER | Output |
| | On exit: the actual number of eigenvalues within the | |
| | interval. | |
| 8: | R(M) -- DOUBLE PRECISION array | Output |
| | On exit: the eigenvalues, not necessarily in ascending | |
| | order. | |
| 9: | V(IV,M) -- DOUBLE PRECISION array | Output |
| | On exit: the eigenvectors, stored by columns. The ith | |
| | column corresponds to the ith eigenvalue. The eigenvectors | |
| | are normalised so that the sum of the squares of the | |
| | elements are equal to 1. | |
| 10: | IV -- INTEGER | Input |
| | On entry: | |
| | the first dimension of the array V as declared in the | |
| | (sub)program from which F02BBF is called. | |
| | Constraint: IV >= N. | |
| 11: | D(N) -- DOUBLE PRECISION array | Workspace |
| 12: | E(N) -- DOUBLE PRECISION array | Workspace |

13:	E2(N) -- DOUBLE PRECISION array	Workspace
14:	X(N,7) -- DOUBLE PRECISION array	Workspace
15:	G(N) -- DOUBLE PRECISION array	Workspace
16:	C(N) -- LOGICAL array	Workspace
17:	ICOUNT(M) -- INTEGER array	Output
	On exit: ICOUNT(i) contains the number of iterations for the i th eigenvalue.	
18:	IFAIL -- INTEGER	Input/Output
	On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.	
	On exit: IFAIL = 0 unless the routine detects an error (see Section 6).	

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

M is less than the number of eigenvalues in the given interval. On exit MM contains the number of eigenvalues in the interval. Rerun with this value for M.

IFAIL= 2

More than 5 iterations are required to determine any one eigenvector.

7. Accuracy

There is no guarantee of the accuracy of the eigenvectors as the results depend on the original matrix and the multiplicity of the roots. For a detailed error analysis see Wilkinson and Reinsch [1] pp 222 and 436.

8. Further Comments

3

The time taken by the routine is approximately proportional to n

This subroutine should only be used when less than 25% of the eigenvalues and the corresponding eigenvectors are required. Also this subroutine is less efficient with matrices which have multiple eigenvalues.

9. Example

To calculate the eigenvalues lying between -2.0 and 3.0, and the corresponding eigenvectors of the real symmetric matrix:

```
( 0.5  0.0  2.3 -2.6)
( 0.0  0.5 -1.4 -0.7)
( 2.3 -1.4  0.5  0.0).
(-2.6 -0.7  0.0  0.5)
```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%

```
F02 -- Eigenvalue and Eigenvectors                                F02BJF
F02BJF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02BJF calculates all the eigenvalues and, if required, all the eigenvectors of the generalized eigenproblem $Ax=(\lambda)Bx$ where A and B are real, square matrices, using the QZ algorithm.

2. Specification

```
SUBROUTINE F02BJF (N, A, IA, B, IB, EPS1, ALFR, ALFI,
1                BETA, MATV, V, IV, ITER, IFAIL)
INTEGER          N, IA, IB, IV, ITER(N), IFAIL
DOUBLE PRECISION A(IA,N), B(IB,N), EPS1, ALFR(N), ALFI(N),
1                BETA(N), V(IV,N)
LOGICAL          MATV
```

3. Description

All the eigenvalues and, if required, all the eigenvectors of the generalized eigenproblem $Ax=(\lambda)Bx$ where A and B are real, square matrices, are determined using the QZ algorithm. The QZ algorithm consists of 4 stages:

- (a) A is reduced to upper Hessenberg form and at the same time B is reduced to upper triangular form.
- (b) A is further reduced to quasi-triangular form while the triangular form of B is maintained.
- (c) The quasi-triangular form of A is reduced to triangular form and the eigenvalues extracted. This routine does not actually produce the eigenvalues $(\lambda)_j$, but instead returns $(\alpha)_j$ and $(\beta)_j$ such that

$$(\lambda)_j = (\alpha)_j / (\beta)_j, \quad j=1,2,\dots,n$$

The division by $(\beta)_j$ becomes the responsibility of the user's program, since $(\beta)_j$ may be zero indicating an infinite eigenvalue. Pairs of complex eigenvalues occur with $(\alpha)_j / (\beta)_j$ and $(\alpha)_{j+1} / (\beta)_{j+1}$ complex conjugates, even though $(\alpha)_j$ and $(\alpha)_{j+1}$ are not conjugate.

- (d) If the eigenvectors are required ($MATV = .TRUE.$), they are obtained from the triangular matrices and then transformed back into the original co-ordinate system.

- [3] Wilkinson J H (1979) Kronecker's Canonical Form and the QZ

Algorithm. Linear Algebra and Appl. 28 285--303.

5. Parameters

- 1: N -- INTEGER Input
On entry: n, the order of the matrices A and B.

- 2: A(IA,N) -- DOUBLE PRECISION array Input/Output
On entry: the n by n matrix A. On exit: the array is overwritten.

- 3: IA -- INTEGER Input
On entry:
the first dimension of the array A as declared in the
(sub)program from which F02BJF is called.
Constraint: IA \geq N.

- 4: B(IB,N) -- DOUBLE PRECISION array Input/Output
On entry: the n by n matrix B. On exit: the array is overwritten.

- 5: IB -- INTEGER Input
On entry:
the first dimension of the array B as declared in the
(sub)program from which F02BJF is called.
Constraint: IB \geq N.

- 6: EPS1 -- DOUBLE PRECISION Input
On entry: the tolerance used to determine negligible elements. If EPS1 > 0.0, an element will be considered negligible if it is less than EPS1 times the norm of its matrix. If EPS1 \leq 0.0, machine precision is used in place of EPS1. A positive value of EPS1 may result in faster execution but less accurate results.

- 7: ALFR(N) -- DOUBLE PRECISION array Output

- 8: ALFI(N) -- DOUBLE PRECISION array Output
On exit: the real and imaginary parts of (alpha) , for
j
j=1,2,...,n.

- 9: BETA(N) -- DOUBLE PRECISION array Output
On exit: (beta) , for j=1,2,...,n.
j

10: MATV -- LOGICAL Input
 On entry: MATV must be set .TRUE. if the eigenvectors are required, otherwise .FALSE..

11: V(IV,N) -- DOUBLE PRECISION array Output
 On exit: if MATV = .TRUE., then
 (i) if the jth eigenvalue is real, the jth column of V contains its eigenvector;

 (ii) if the jth and (j+1)th eigenvalues form a complex pair, the jth and (j+1)th columns of V contain the real and imaginary parts of the eigenvector associated with the first eigenvalue of the pair. The conjugate of this vector is the eigenvector for the conjugate eigenvalue.

Each eigenvector is normalised so that the component of largest modulus is real and the sum of squares of the moduli equal one.

If MATV = .FALSE., V is not used.

12: IV -- INTEGER Input
 On entry:
 the first dimension of the array V as declared in the (sub)program from which F02BJF is called.
 Constraint: IV >= N.

13: ITER(N) -- INTEGER array Output
 On exit: ITER(j) contains the number of iterations needed to obtain the jth eigenvalue. Note that the eigenvalues are obtained in reverse order, starting with the nth.

14: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= i

More than 30*N iterations are required to determine all the

diagonal 1 by 1 or 2 by 2 blocks of the quasi-triangular form in the second step of the QZ algorithm. IFAIL is set to the index i of the eigenvalue at which this failure occurs. If the soft failure option is used, $(\alpha)_j$ and $(\beta)_j$ are correct for $j=i+1, i+2, \dots, n$, but V does not contain any correct eigenvectors.

7. Accuracy

The computed eigenvalues are always exact for a problem $(A+E)x=(\lambda)(B+F)x$ where $\|E\|/\|A\|$ and $\|F\|/\|B\|$ are both of the order of $\max(\text{EPS1}, (\epsilon))$, EPS1 being defined as in Section 5 and (ϵ) being the machine precision.

Note: interpretation of results obtained with the QZ algorithm often requires a clear understanding of the effects of small changes in the original data. These effects are reviewed in Wilkinson [3], in relation to the significance of small values of $(\alpha)_j$ and $(\beta)_j$. It should be noted that if $(\alpha)_j$ and $(\beta)_j$ are both small for any j , it may be that no reliance can be placed on any of the computed eigenvalues $(\lambda)_i = (\alpha)_i / (\beta)_i$. The user is recommended to study [3] and, if in difficulty, to seek expert advice on determining the sensitivity of the eigenvalues to perturbations in the data.

8. Further Comments

3

The time taken by the routine is approximately proportional to n and also depends on the value chosen for parameter EPS1.

9. Example

To find all the eigenvalues and eigenvectors of $Ax=(\lambda) Bx$ where

$$A = \begin{pmatrix} 3.9 & 12.5 & -34.5 & -0.5 \\ 4.3 & 21.5 & -47.5 & 7.5 \\ 4.3 & 21.5 & -43.5 & 3.5 \\ 4.4 & 26.0 & -46.0 & 6.0 \end{pmatrix}$$

and

```

      (1 2 -3 1)
      (1 3 -5 4)
B=(1 3 -4 3).
      (1 3 -4 4)

```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%

F02 -- Eigenvalue and Eigenvectors F02FJF
 F02FJF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

To find eigenvalues and eigenvectors of a real sparse symmetric or generalized symmetric eigenvalue problem.

2. Specification

```

      SUBROUTINE F02FJF (N, M, K, NOITS, TOL, DOT, IMAGE, MONIT,
1                      NOVECS, X, NRX, D, WORK, LWORK, RWORK,
2                      LRWORK, IWORK, LIWORK, IFAIL)
      INTEGER          N, M, K, NOITS, NOVECS, NRX, LWORK,
1                      LRWORK, IWORK(LIWORK), LIWORK, IFAIL
      DOUBLE PRECISION TOL, DOT, X(NRX,K), D(K), WORK(LWORK),
1                      RWORK(LRWORK)
      EXTERNAL         DOT, IMAGE, MONIT

```

3. Description

F02FJF finds the m eigenvalues of largest absolute value and the corresponding eigenvectors for the real eigenvalue problem

$$Cx = (\lambda)x \quad (1)$$

where C is an n by n matrix such that

T

$$BC = C^T B \quad (2)$$

for a given positive-definite matrix B . C is said to be B -symmetric. Different specifications of C allow for the solution of a variety of eigenvalue problems. For example, when

$$C = A \text{ and } B = I \text{ where } A = A^T$$

the routine finds the m eigenvalues of largest absolute magnitude for the standard symmetric eigenvalue problem

$$Ax = (\lambda)x. \quad (3)$$

The routine is intended for the case where A is sparse.

As a second example, when

$$C = B^{-1} A$$

where

$$A = A^T$$

the routine finds the m eigenvalues of largest absolute magnitude for the generalized symmetric eigenvalue problem

$$Ax = (\lambda)Bx. \quad (4)$$

The routine is intended for the case where A and B are sparse.

The routine does not require C explicitly, but C is specified via a user-supplied routine `IMAGE` which, given an n element vector z , computes the image w given by

$$w = Cz.$$

For instance, in the above example, where $C = B^{-1} A$, routine `IMAGE` will need to solve the positive-definite system of equations $Bw = Az$ for w .

To find the m eigenvalues of smallest absolute magnitude of (3)

we can choose $C=A$ and hence find the reciprocals of the required eigenvalues, so that IMAGE will need to solve $Aw=z$ for w , and correspondingly for (4) we can choose $C=A^{-1}B$ and solve $Aw=Bz$ for w .

A table of examples of choice of IMAGE is given in Table 3.1. It should be remembered that the routine also returns the corresponding eigenvectors and that B is positive-definite. Throughout A is assumed to be symmetric and, where necessary, non-singularity is also assumed.

Eigenvalues Required	Problem		
	$Ax=(\lambda)x$	$(B-I)Ax=(\lambda)Bx$	$ABx=(\lambda)x$
Largest	Compute $w=Az$	Solve $Bw=Az$	Compute $w=ABz$
Smallest (Find $1/(\lambda)$)	Solve $Aw=z$	Solve $Aw=Bz$	Solve $Av=z, Bw=(\nu)$
Furthest from (σ) (Find $(\lambda)-(\sigma)$)	Compute $w=(A-(\sigma)I)z$	Solve $Bw=(A-(\sigma)B)z$	Compute $w=(AB-(\sigma)I)z$
Closest to (σ) (Find $1/((\lambda)-(\sigma))$)	Solve $(A-(\sigma)I)w=z$	Solve $(A-(\sigma)B)w=Bz$	Solve $(AB-(\sigma)I)w=z$

Table 3.1
The Requirement of IMAGE for Various Problems

The matrix B also need not be supplied explicitly, but is specified via a user-supplied routine DOT which, given n element vectors z and w , computes the generalized dot product $w^T Bz$.

F02FJF is based upon routine SIMITZ (see Nikolai [1]), which is itself a derivative of the Algol procedure ritzit (see Rutishauser [4]), and uses the method of simultaneous (subspace) iteration. (See Parlett [2] for description, analysis and advice on the use of the method.)

The routine performs simultaneous iteration on $k > m$ vectors. Initial estimates to $p \leq k$ eigenvectors, corresponding to the p eigenvalues of C of largest absolute value, may be supplied by the user to F02FJF. When possible k should be chosen so that the k th eigenvalue is not too close to the m required eigenvalues, but if k is initially chosen too small then F02FJF may be re-entered, supplying approximations to the k eigenvectors found so far and with k then increased.

At each major iteration F02FJF solves an r by r ($r \leq k$) eigenvalue sub-problem in order to obtain an approximation to the eigenvalues for which convergence has not yet occurred. This approximation is refined by Chebyshev acceleration.

4. References

- [2] Parlett B N (1980) The Symmetric Eigenvalue Problem. Prentice-Hall.
- [3] Rutishauser H (1969) Computational aspects of F L Bauer's simultaneous iteration method. Num. Math. 13 4--13.
- [4] Rutishauser H (1970) Simultaneous iteration method for symmetric matrices. Num. Math. 16 205--223.

5. Parameters

- 1: N -- INTEGER Input
On entry: n , the order of the matrix C . Constraint: $N \geq 1$.
- 2: M -- INTEGER Input/Output
On entry: m , the number of eigenvalues required.
Constraint: $M \geq 1$. On exit: m , the number of eigenvalues actually found. It is equal to m if IFAIL = 0 on exit, and is less than m if IFAIL = 2, 3 or 4. See Section 6 and

Section 8 for further information.

- 3: K -- INTEGER Input
 On entry: the number of simultaneous iteration vectors to be used. Too small a value of K may inhibit convergence, while a larger value of K incurs additional storage and additional work per iteration. Suggested value: $K = M + 4$ will often be a reasonable choice in the absence of better information. Constraint: $M < K \leq N$.
- 4: NOITS -- INTEGER Input/Output
 On entry: the maximum number of major iterations (eigenvalue sub-problems) to be performed. If $\text{NOITS} \leq 0$, then the value 100 is used in place of NOITS. On exit: the number of iterations actually performed.
- 5: TOL -- DOUBLE PRECISION Input
 On entry: a relative tolerance to be used in accepting eigenvalues and eigenvectors. If the eigenvalues are required to about t significant figures, then TOL should be $-t$
 set to about 10^{-t} . d_i is accepted as an eigenvalue as soon as two successive approximations to d_i differ by less than $\frac{|d_i| * \text{TOL}}{10}$, where d_i is the latest approximation to d_i .
 Once an eigenvalue has been accepted, then an eigenvector is accepted as soon as $\frac{(d_i f_i)}{(d_i - d_k)} < \text{TOL}$, where f_i is the normalised residual of the current approximation to the eigenvector (see Section 8 for further information). The values of the f_i and d_i can be printed from routine MONIT.
 If TOL is supplied outside the range $((\text{epsilon}), 1.0)$, where (epsilon) is the machine precision, then the value (epsilon) is used in place of TOL.
- 6: DOT -- DOUBLE PRECISION FUNCTION, supplied by the user. External Procedure
 T
 T
 DOT must return the value $w^T B z$ for given vectors w and z . For the standard eigenvalue problem, where $B=I$, DOT must T
 return the dot product $w^T z$.

Its specification is:

```

      DOUBLE PRECISION FUNCTION DOT (IFLAG, N, Z, W,
1                                     RWORK, LRWORK,
2                                     IWORK, LIWORK)
      INTEGER          IFLAG, N, LRWORK, IWORK(LIWORK),
1                     LIWORK
      DOUBLE PRECISION Z(N), W(N), RWORK(LRWORK)

```

- 1: IFLAG -- INTEGER Input/Output
 On entry: IFLAG is always non-negative. On exit: IFLAG may be used as a flag to indicate a failure in the computation of $w^T Bz$. If IFLAG is negative on exit from DOT, then F02FJF will exit immediately with IFAIL set to IFLAG. Note that in this case DOT must still be assigned a value.
- 2: N -- INTEGER Input
 On entry: the number of elements in the vectors z and w and the order of the matrix B .
- 3: Z(N) -- DOUBLE PRECISION array Input
T
 On entry: the vector z for which $w^T Bz$ is required.
- 4: W(N) -- DOUBLE PRECISION array Input
T
 On entry: the vector w for which $w^T Bz$ is required.
- 5: RWORK(LRWORK) -- DOUBLE PRECISION array User Workspace
- 6: LRWORK -- INTEGER Input
- 7: IWORK(LIWORK) -- INTEGER array User Workspace
- 8: LIWORK -- INTEGER Input
 DOT is called from F02FJF with the parameters RWORK, LRWORK, IWORK and LIWORK as supplied to F02FJF. The user is free to use the arrays RWORK and IWORK to supply information to DOT and to IMAGE as an alternative to using COMMON.

DOT must be declared as EXTERNAL in the (sub)program from which F02FJF is called. Parameters denoted as Input must not be changed by this procedure.

7: IMAGE -- SUBROUTINE, supplied by the user.

External Procedure

IMAGE must return the vector $w=Cz$ for a given vector z .

Its specification is:

```

SUBROUTINE IMAGE (IFLAG, N, Z, W, RWORK, LRWORK,
1                IWORK, LIWORK)
  INTEGER          IFLAG, N, LRWORK, IWORK(LIWORK),
1                LIWORK
  DOUBLE PRECISION Z(N), W(N), RWORK(LRWORK)

```

- 1: IFLAG -- INTEGER Input/Output
 On entry: IFLAG is always non-negative. On exit: IFLAG may be used as a flag to indicate a failure in the computation of w . If IFLAG is negative on exit from IMAGE, then F02FJF will exit immediately with IFAIL set to IFLAG.
- 2: N -- INTEGER Input
 On entry: n , the number of elements in the vectors w and z , and the order of the matrix C .
- 3: Z(N) -- DOUBLE PRECISION array Input
 On entry: the vector z for which Cz is required.
- 4: W(N) -- DOUBLE PRECISION array Output
 On exit: the vector $w=Cz$.
- 5: RWORK(LRWORK) -- DOUBLE PRECISION array User Workspace
- 6: LRWORK -- INTEGER Input
- 7: IWORK(LIWORK) -- INTEGER array User Workspace
- 8: LIWORK -- INTEGER Input
 IMAGE is called from F02FJF with the parameters RWORK, LRWORK, IWORK and LIWORK as supplied to F02FJF. The user is free to use the arrays RWORK and IWORK to supply information to IMAGE and DOT as an alternative to using COMMON.

IMAGE must be declared as EXTERNAL in the (sub)program

from which F02FJF is called. Parameters denoted as Input must not be changed by this procedure.

- 8: MONIT -- SUBROUTINE, supplied by the user.

External Procedure

MONIT is used to monitor the progress of F02FJF. MONIT may be the dummy subroutine F02FJZ if no monitoring is actually required. (F02FJZ is included in the NAG Foundation Library and so need not be supplied by the user. The routine name F02FJZ may be implementation dependent: see the Users' Note for your implementation for details.) MONIT is called after the solution of each eigenvalue sub-problem and also just prior to return from F02FJF. The parameters ISTATE and NEXTIT allow selective printing by MONIT.

Its specification is:

```

SUBROUTINE MONIT (ISTATE, NEXTIT, NEVALS,
1               NEVECS, K, F, D)
  INTEGER          ISTATE, NEXTIT, NEVALS, NEVECS,
1               K
  DOUBLE PRECISION F(K), D(K)

```

- 1: ISTATE -- INTEGER Input

On entry: ISTATE specifies the state of F02FJF and will have values as follows:

ISTATE = 0

No eigenvalue or eigenvector has just been accepted.

ISTATE = 1

One or more eigenvalues have been accepted since the last call to MONIT.

ISTATE = 2

One or more eigenvectors have been accepted since the last call to MONIT.

ISTATE = 3

One or more eigenvalues and eigenvectors have been accepted since the last call to MONIT.

ISTATE = 4

Return from F02FJF is about to occur.

- 2: NEXTIT -- INTEGER

Input

On entry: the number of the next iteration.

3: NEVALS -- INTEGER Input
On entry: the number of eigenvalues accepted so far.

4: NEVECS -- INTEGER Input
On entry: the number of eigenvectors accepted so far.

5: K -- INTEGER Input
On entry: k, the number of simultaneous iteration vectors.

6: F(K) -- DOUBLE PRECISION array Input
On entry: a vector of error quantities measuring the state of convergence of the simultaneous iteration vectors. See the parameter TOL of F02FJF above and Section 8 for further details. Each element of F is initially set to the value 4.0 and an element remains at 4.0 until the corresponding vector is tested.

7: D(K) -- DOUBLE PRECISION array Input
On entry: D(i) contains the latest approximation to the absolute value of the ith eigenvalue of C.

MONIT must be declared as EXTERNAL in the (sub)program from which F02FJF is called. Parameters denoted as Input must not be changed by this procedure.

9: NOVECS -- INTEGER Input
On entry: the number of approximate vectors that are being supplied in X. If NOVECS is outside the range (0,K), then the value 0 is used in place of NOVECS.

10: X(NRX,K) -- DOUBLE PRECISION array Input/Output
On entry: if $0 < \text{NOVECS} \leq K$, the first NOVECS columns of X must contain approximations to the eigenvectors corresponding to the NOVECS eigenvalues of largest absolute value of C. Supplying approximate eigenvectors can be useful when reasonable approximations are known, or when the routine is being restarted with a larger value of K. Otherwise it is not necessary to supply approximate vectors, as simultaneous iteration vectors will be generated randomly by the routine. On exit: if IFAIL = 0, 2, 3 or 4, the first m' columns contain the eigenvectors corresponding to the eigenvalues returned in the first m' elements of D (see below); and the next k-m'-1 columns contain approximations to the eigenvectors corresponding to the approximate

eigenvalues returned in the next $k-m'-1$ elements of D . Here m' is the value returned in M (see above), the number of eigenvalues actually found. The k th column is used as workspace.

- 11: NRX -- INTEGER Input
 On entry:
 the first dimension of the array X as declared in the
 (sub)program from which F02FJF is called.
 Constraint: $NRX \geq N$.

- 12: D(K) -- DOUBLE PRECISION array Output
 On exit: if IFAIL = 0, 2, 3 or 4, the first m' elements
 contain the first m' eigenvalues in decreasing order of
 magnitude; and the next $k-m'-1$ elements contain
 approximations to the next $k-m'-1$ eigenvalues. Here m' is
 the value returned in M (see above), the number of
 eigenvalues actually found. $D(k)$ contains the value e where
 $(-e, e)$ is the latest interval over which Chebyshev
 acceleration is performed.

- 13: WORK(LWORK) -- DOUBLE PRECISION array Workspace

- 14: LWORK -- INTEGER Input
 On entry: the length of the array WORK, as declared in the
 (sub)program from which F02FJF is called. Constraint:
 $LWORK \geq 3*K + \max(K*K, 2*N)$.

- 15: RWORK(LRWORK) -- DOUBLE PRECISION array User Workspace
 RWORK is not used by F02FJF, but is passed directly to
 routines DOT and IMAGE and may be used to supply information
 to these routines.

- 16: LRWORK -- INTEGER Input
 On entry: the length of the array RWORK, as declared in the
 (sub)program from which F02FJF is called. Constraint: $LRWORK$
 ≥ 1 .

- 17: IWORK(LIWORK) -- INTEGER array User Workspace
 IWORK is not used by F02FJF, but is passed directly to
 routines DOT and IMAGE and may be used to supply information
 to these routines.

- 18: LIWORK -- INTEGER Input
 On entry: the length of the array IWORK, as declared in the
 (sub)program from which F02FJF is called. Constraint: $LIWORK$

≥ 1 .

19: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL \neq 0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit. To suppress the output of an error message when soft failure occurs, set IFAIL to 1.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

IFAIL < 0

A negative value of IFAIL indicates an exit from F02FJF because the user has set IFLAG negative in DOT or IMAGE. The value of IFAIL will be the same as the user's setting of IFLAG.

IFAIL = 1

On entry $N < 1$,

or $M < 1$,

or $M \geq K$,

or $K > N$,

or $NRX < N$,

or $LWORK < 3 \cdot K + \max(K \cdot K, N)$,

or $LRWORK < 1$,

or $LIWORK < 1$.

IFAIL = 2

Not all the requested eigenvalues and vectors have been obtained. Approximations to the r th eigenvalue are oscillating rapidly indicating that severe cancellation is occurring in the r th eigenvector and so M is returned as $(r-1)$. A restart with a larger value of K may permit convergence.

IFAIL= 3

Not all the requested eigenvalues and vectors have been obtained. The rate of convergence of the remaining eigenvectors suggests that more than NOITS iterations would be required and so the input value of M has been reduced. A restart with a larger value of K may permit convergence.

IFAIL= 4

Not all the requested eigenvalues and vectors have been obtained. NOITS iterations have been performed. A restart, possibly with a larger value of K , may permit convergence.

IFAIL= 5

This error is very unlikely to occur, but indicates that convergence of the eigenvalue sub-problem has not taken place. Restarting with a different set of approximate vectors may allow convergence. If this error occurs the user should check carefully that F02FJF is being called correctly.

7. Accuracy

Eigenvalues and eigenvectors will normally be computed to the accuracy requested by the parameter TOL, but eigenvectors corresponding to small or to close eigenvalues may not always be computed to the accuracy requested by the parameter TOL. Use of the routine MONIT to monitor acceptance of eigenvalues and eigenvectors is recommended.

8. Further Comments

The time taken by the routine will be principally determined by the time taken to solve the eigenvalue sub-problem and the time taken by the routines DOT and IMAGE. The time taken to solve an eigenvalue sub-problem is approximately proportional to n^2 . It is important to be aware that several calls to DOT and IMAGE may occur on each major iteration.

As can be seen from Table 3.1, many applications of F02FJF will require routine IMAGE to solve a system of linear equations. For example, to find the smallest eigenvalues of $Ax=(\lambda)Bx$, IMAGE needs to solve equations of the form $Aw=Bz$ for w and routines from Chapters F01 and F04 of the NAG Foundation Library will frequently be useful in this context. In particular, if A is a positive-definite variable band matrix, F04MCF may be used after A has been factorized by F01MCF. Thus factorization need be performed only once prior to calling F02FJF. An illustration of this type of use is given in the example program in Section 9.

An approximation d_h , to the i th eigenvalue, is accepted as soon

as d_h and the previous approximation differ by less than

$|d_h|*TOL/10$. Eigenvectors are accepted in groups corresponding to

clusters of eigenvalues that are equal, or nearly equal, in absolute value and that have already been accepted. If d_r is the last eigenvalue in such a group and we define the residual r_j as

$$r_j = Cx_j - y_j$$

where y_r is the projection of Cx_j , with respect to B , onto the space spanned by x_1, x_2, \dots, x_r and x_j is the current approximation to the j th eigenvector, then the value f_i returned in MONIT is given by

$$f_i = \max_j \frac{\|r_j\|^2}{\|Cx_j\|^2} \quad \frac{\|x_j\|^2}{\|Bx_j\|^2}$$

and each vector in the group is accepted as an eigenvector if

$$(|d_r|/f_r)/(|d_r|-e) < TOL$$

```

      (      b 1 b      )
      (      b 1 b      )
      (      b 1 b      )
B=(      b 1 b      )
      (      b 1 b      )
      (      b 1 b      )
      (      b 1 b      )
      (      b 1 b      )
      (      b 1 b      )
      (      b 1 b      )
      (      b 1 b      )

```

1
 where $b = -\frac{1}{2}$

TOL is taken as 0.0001 and 6 iteration vectors are used. F01MAF is used to factorize the matrix A, prior to calling F02FJF, and F04MAF is used within IMAGE to solve the equations $Aw=Bz$ for w. Details of the factorization of A are passed from F01MAF to F04MAF by means of the COMMON block BLOCK1.

Output from MONIT occurs each time ISTATE is non-zero. Note that the required eigenvalues are the reciprocals of the eigenvalues returned by F02FJF.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F02 -- Eigenvalue and Eigenvectors F02WEF
 F02WEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02WEF returns all, or part, of the singular value decomposition of a general real matrix.

2. Specification

```

SUBROUTINE F02WEF (M, N, A, LDA, NCOLB, B, LDB, WANTQ, Q,
1                LDQ, SV, WANTP, PT, LDPT, WORK, IFAIL)
INTEGER          M, N, LDA, NCOLB, LDB, LDQ, LDPT, IFAIL
DOUBLE PRECISION A(LDA,*), B(LDB,*), Q(LDQ,*), SV(*), PT
1                (LDPT,*), WORK(*)
LOGICAL          WANTQ, WANTP

```

3. Description

The m by n matrix A is factorized as

$$A = QDP^T,$$

where

$$\begin{aligned}
 D &= \begin{pmatrix} S \\ 0 \end{pmatrix}, & m > n, \\
 D &= S, & m = n, \\
 D &= \begin{pmatrix} S & 0 \end{pmatrix}, & m < n,
 \end{aligned}$$

Q is an m by m orthogonal matrix, P is an n by n orthogonal matrix and S is a $\min(m,n)$ by $\min(m,n)$ diagonal matrix with non-negative diagonal elements, $sv_1, sv_2, \dots, sv_{\min(m,n)}$, ordered such

that

$$sv_1 \geq sv_2 \geq \dots \geq sv_{\min(m,n)} \geq 0.$$

The first $\min(m,n)$ columns of Q are the left-hand singular vectors of A , the diagonal elements of S are the singular values of A and the first $\min(m,n)$ columns of P are the right-hand singular vectors of A .

Either or both of the left-hand and right-hand singular vectors of A may be requested and the matrix C given by

$$C = Q^T B,$$

where B is an m by $ncolb$ given matrix, may also be requested.

The routine obtains the singular value decomposition by first reducing A to upper triangular form by means of Householder transformations, from the left when $m \geq n$ and from the right when $m < n$. The upper triangular form is then reduced to bidiagonal form by Givens plane rotations and finally the QR algorithm is used to obtain the singular value decomposition of the bidiagonal form.

Good background descriptions to the singular value decomposition are given in Dongarra et al [1], Hammarling [2] and Wilkinson [3] DSVDC.

Note that if K is any orthogonal diagonal matrix so that

$$K^T K = I,$$

(so that K has elements +1 or -1 on the diagonal)

then

$$A = (QK) D (PK)^T$$

is also a singular value decomposition of A.

5. Parameters

1: M -- INTEGER Input
 On entry: the number of rows, m, of the matrix A.
 Constraint: M \geq 0.

When M = 0 then an immediate return is effected.

2: N -- INTEGER Input

On entry: the number of columns, n , of the matrix A .
 Constraint: $N \geq 0$.

When $N = 0$ then an immediate return is effected.

- 3: $A(LDA,*)$ -- DOUBLE PRECISION array Input/Output
 Note: the second dimension of the array A must be at least $\max(1, N)$.

On entry: the leading m by n part of the array A must contain the matrix A whose singular value decomposition is required. On exit: if $M \geq N$ and $WANTQ = .TRUE.$, then the leading m by n part of A will contain the first n columns of the orthogonal matrix Q .

If $M < N$ and $WANTP = .TRUE.$, then the leading m by n part of A will contain the first m rows of the orthogonal matrix P^T .

If $M \geq N$ and $WANTQ = .FALSE.$ and $WANTP = .TRUE.$, then the leading n by n part of A will contain the first n rows of the orthogonal matrix P^T .

Otherwise the leading m by n part of A is used as internal workspace.

- 4: LDA -- INTEGER Input
 On entry:
 the first dimension of the array A as declared in the (sub)program from which F02WEF is called.
 Constraint: $LDA \geq \max(1, M)$.

- 5: $NCOLB$ -- INTEGER Input
 On entry: $ncolb$, the number of columns of the matrix B .
 When $NCOLB = 0$ the array B is not referenced. Constraint:
 $NCOLB \geq 0$.

- 6: $B(LDB,*)$ -- DOUBLE PRECISION array Input/Output
 Note: the second dimension of the array B must be at least $\max(1, ncolb)$ On entry: if $NCOLB > 0$, the leading m by $ncolb$ part of the array B must contain the matrix to be transformed. On exit: B is overwritten by the m by $ncolb$ matrix $Q^T B$.

- 7: LDB -- INTEGER Input

On entry:

the first dimension of the array B as declared in the (sub)program from which F02WEF is called.

Constraint: if NCOLB > 0 then LDB >= max(1,M).

8: WANTQ -- LOGICAL Input
 On entry: WANTQ must be .TRUE., if the left-hand singular vectors are required. If WANTQ = .FALSE., then the array Q is not referenced.

9: Q(LDQ,*) -- DOUBLE PRECISION array Output
 Note: the second dimension of the array Q must be at least max(1,M).
 On exit: if M < N and WANTQ = .TRUE., the leading m by m part of the array Q will contain the orthogonal matrix Q. Otherwise the array Q is not referenced.

10: LDQ -- INTEGER Input
 On entry:
 the first dimension of the array Q as declared in the (sub)program from which F02WEF is called.
 Constraint: if M < N and WANTQ = .TRUE., LDQ >= max(1,M).

11: SV(*) -- DOUBLE PRECISION array Output
 Note: the length of SV must be at least min(M,N). On exit: the min(M,N) diagonal elements of the matrix S.

12: WANTP -- LOGICAL Input
 On entry: WANTP must be .TRUE. if the right-hand singular vectors are required. If WANTP = .FALSE., then the array PT is not referenced.

13: PT(LDPT,*) -- DOUBLE PRECISION array Output
 Note: the second dimension of the array PT must be at least max(1,N).
 On exit: if M >= N and WANTQ and WANTP are .TRUE., the leading n by n part of the array PT will contain the

$$T$$

 orthogonal matrix P^T. Otherwise the array PT is not referenced.

14: LDPT -- INTEGER Input
 On entry:
 the first dimension of the array PT as declared in the (sub)program from which F02WEF is called.
 Constraint: if M >= N and WANTQ and WANTP are .TRUE., LDPT

$\geq \max(1, N)$.

- 15: WORK(*) -- DOUBLE PRECISION array Output
 Note: the length of WORK must be at least $\max(1, \text{lwork})$,
 where lwork must be as given in the following table:

$M \geq N$

WANTQ is .TRUE. and WANTP = .TRUE.

2

$\text{lwork} = \max(N + 5*(N-1), N + \text{NCOLB}, 4)$

WANTQ = .TRUE. and WANTP = .FALSE.

2

$\text{lwork} = \max(N + 4*(N-1), N + \text{NCOLB}, 4)$

WANTQ = .FALSE. and WANTP = .TRUE.

$\text{lwork} = \max(3*(N-1), 2)$ when $\text{NCOLB} = 0$

$\text{lwork} = \max(5*(N-1), 2)$ when $\text{NCOLB} > 0$

WANTQ = .FALSE. and WANTP = .FALSE.

$\text{lwork} = \max(2*(N-1), 2)$ when $\text{NCOLB} = 0$

$\text{lwork} = \max(3*(N-1), 2)$ when $\text{NCOLB} > 0$

$M < N$

WANTQ = .TRUE. and WANTP = .TRUE.

2

$\text{lwork} = \max(M + 5*(M-1), 2)$

WANTQ = .TRUE. and WANTP = .FALSE.

$\text{lwork} = \max(3*(M-1), 1)$

WANTQ = .FALSE. and WANTP = .TRUE.

2

$\text{lwork} = \max(M + 3*(M-1), 2)$ when $\text{NCOLB} = 0$

2

$\text{lwork} = \max(M + 5*(M-1), 2)$ when $\text{NCOLB} > 0$

WANTQ = .FALSE. and WANTP = .FALSE.

$\text{lwork} = \max(2*(M-1), 1)$ when $\text{NCOLB} = 0$

$\text{lwork} = \max(3*(M-1), 1)$ when $\text{NCOLB} > 0$

On exit: WORK(min(M,N)) contains the total number of
 iterations taken by the R algorithm.

The rest of the array is used as workspace.

16: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL=-1

One or more of the following conditions holds:

$M < 0$,

$N < 0$,

$LDA < M$,

$NCOLB < 0$,

$LDB < M$ and $NCOLB > 0$,

$LDQ < M$ and $M < N$ and $WANTQ = .TRUE.$,

$LDPT < N$ and $M \geq N$ and $WANTQ = .TRUE.$, and $WANTP = .TRUE.$.

IFAIL> 0

The QR algorithm has failed to converge in $50 \times \min(m,n)$ iterations. In this case $SV(1)$, $SV(2)$, ..., $SV(IFAIL)$ may not have been found correctly and the remaining singular values may not be the smallest. The matrix A will nevertheless have

T

been factorized as $A = QEP^T$, where the leading $\min(m,n)$ by $\min(m,n)$ part of E is a bidiagonal matrix with $SV(1)$, $SV(2)$, ..., $SV(\min(m,n))$ as the diagonal elements and $WORK(1)$, $WORK(2)$, ..., $WORK(\min(m,n)-1)$ as the super-diagonal elements.

This failure is not likely to occur.

7. Accuracy

The computed factors Q, D and P satisfy the relation

$$QDP^T = A + E,$$

where

$$\|E\| \leq c(\text{epsilon}) \|A\|,$$

(epsilon) being the machine precision, c is a modest function of m and n and $\|.\|$ denotes the spectral (two) norm. Note that $\|A\| = \text{sv}_1$.

8. Further Comments

Following the use of this routine the rank of A may be estimated by a call to the INTEGER FUNCTION F06KLF(*). The statement:

```
IRANK = F06KLF(MIN(M, N), SV, 1, TOL)
```

returns the value (k-1) in IRANK, where k is the smallest integer for which $SV(k) < \text{tol} * SV(1)$, where tol is the tolerance supplied in TOL, so that IRANK is an estimate of the rank of S and thus also of A. If TOL is supplied as negative then the machine precision is used in place of TOL.

9. Example

9.1. Example 1

To find the singular value decomposition of the 5 by 3 matrix

$$A = \begin{pmatrix} 2.0 & 2.5 & 2.5 \\ 2.0 & 2.5 & 2.5 \\ 1.6 & -0.4 & 2.8 \\ 2.0 & -0.5 & 0.5 \\ 1.2 & -0.3 & -2.9 \end{pmatrix}$$

together with the vector $Q^T b$ for the vector

```

      ( 1.1)
      ( 0.9)
      b=( 0.6)
      ( 0.0)
      (-0.8)

```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

9.2. Example 2

To find the singular value decomposition of the 3 by 5 matrix

```

      (2.0 2.0 1.6 2.0 1.2)
      A=(2.5 2.5 -0.4 -0.5 -0.3)
      (2.5 2.5 2.8 0.5 -2.9)

```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F02 -- Eigenvalue and Eigenvectors F02XEF
 F02XEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F02XEF returns all, or part, of the singular value decomposition of a general complex matrix.

2. Specification

```

      SUBROUTINE F02XEF (M, N, A, LDA, NCOLB, B, LDB, WANTQ, Q,
1                      LDQ, SV, WANTP, PH, LDPH, RWORK, CWORK,
2                      IFAIL)
      INTEGER          M, N, LDA, NCOLB, LDB, LDQ, LDPH,
1                      IFAIL
      DOUBLE PRECISION SV(*), RWORK(*)
      COMPLEX(KIND=KIND(1.0D0)) A(LDA,*), B(LDB,*), Q(LDQ,*),

```

3. Description

$$A = QDP^H,$$

that

$$\begin{array}{c} \text{H} \\ | \\ \text{C}=\text{Q} \quad \text{B}, \end{array}$$

The routine obtains the singular value decomposition by first reducing A to upper triangular form by means of Householder transformations, from the left when $m \geq n$ and from the right when $m < n$. The upper triangular form is then reduced to bidiagonal form by Givens plane rotations and finally the QR algorithm is used to

obtain the singular value decomposition of the bidiagonal form.

Good background descriptions to the singular value decomposition are given in Dongarra et al [1], Hammarling [2] and Wilkinson [3] ZSVDC.

Note that if K is any unitary diagonal matrix so that

$$K^H K = I,$$

then

$$A = (QK)D(PK)^H$$

is also a singular value decomposition of A .

 On entry: the number of columns, n , of the matrix A .
 Constraint: $N \geq 0$.

 When $N = 0$ then an immediate return is effected.
- 3: $A(LDA,*)$ -- COMPLEX(KIND(1.0D0)) array Input/Output
 Note: the second dimension of the array A must be at least

$\max(1,N)$.

On entry: the leading m by n part of the array A must contain the matrix A whose singular value decomposition is required. On exit: if $M \geq N$ and $\text{WANTQ} = \text{.TRUE.}$, then the leading m by n part of A will contain the first n columns of the unitary matrix Q .

If $M < N$ and $\text{WANTP} = \text{.TRUE.}$, then the leading m by n part of H

A will contain the first m rows of the unitary matrix P . If $M \geq N$ and $\text{WANTQ} = \text{.FALSE.}$ and $\text{WANTP} = \text{.TRUE.}$, then the leading n by n part of A will contain the first n

H rows of the unitary matrix P . Otherwise the leading m by n part of A is used as internal workspace.

- 4: LDA -- INTEGER Input
 On entry:
 the first dimension of the array A as declared in the (sub)program from which F02XEF is called.
 Constraint: $\text{LDA} \geq \max(1,M)$.

- 5: NCOLB -- INTEGER Input
 On entry: ncolb , the number of columns of the matrix B .
 When $\text{NCOLB} = 0$ the array B is not referenced. Constraint:
 $\text{NCOLB} \geq 0$.

- 6: B(LDB,*) -- COMPLEX(KIND(1.0D)) array Input/Output
 Note: the second dimension of the array B must be at least $\max(1,\text{NCOLB})$.
 On entry: if $\text{NCOLB} > 0$, the leading m by ncolb part of the array B must contain the matrix to be transformed. On exit:
 H
 B is overwritten by the m by ncolb matrix $Q B$.

- 7: LDB -- INTEGER Input
 On entry:
 the first dimension of the array B as declared in the (sub)program from which F02XEF is called.
 Constraint: if $\text{NCOLB} > 0$, then $\text{LDB} \geq \max(1,M)$.

- 8: WANTQ -- LOGICAL Input
 On entry: WANTQ must be .TRUE. if the left-hand singular vectors are required. If $\text{WANTQ} = \text{.FALSE.}$ then the array Q is not referenced.

- ```

9: Q(LDQ,*) -- COMPLEX(KIND(1.0D)) array Output
 Note: the second dimension of the array Q must be at least
 max(1,M).
 On exit: if M < N and WANTQ = .TRUE., the leading m by m
 part of the array Q will contain the unitary matrix Q.
 Otherwise the array Q is not referenced.

10: LDQ -- INTEGER Input
 On entry:
 the first dimension of the array Q as declared in the
 (sub)program from which F02XEF is called.
 Constraint: if M < N and WANTQ = .TRUE., LDQ >= max(1,M).

11: SV(*) -- DOUBLE PRECISION array Output
 Note: the length of SV must be at least min(M,N). On exit:
 the min(m,n) diagonal elements of the matrix S.

12: WANTP -- LOGICAL Input
 On entry: WANTP must be .TRUE. if the right-hand singular
 vectors are required. If WANTP = .FALSE. then the array PH
 is not referenced.

13: PH(LDPH,*) -- DOUBLE PRECISION array Output
 Note: the second dimension of the array PH must be at least
 max(1,N).
 On exit: if M >= N and WANTQ and WANTP are .TRUE., the
 leading n by n part of the array PH will contain the unitary
 H
 matrix P . Otherwise the array PH is not referenced.

14: LDPH -- INTEGER Input
 On entry:
 the first dimension of the array PH as declared in the
 (sub)program from which F02XEF is called.
 Constraint: if M >= N and WANTQ and WANTP are .TRUE., LDPH
 >= max(1,N).

15: RWORK(*) -- DOUBLE PRECISION array Output
 Note: the length of RWORK must be at least max(1,lrwork),
 where lrwork must satisfy:
 lrwork=2*(min(M,N)-1) when
 NCOLB = 0 and WANTQ and WANTP are .FALSE.,
 lrwork=3*(min(M,N)-1) when
 either NCOLB = 0 and WANTQ = .FALSE. and WANTP = .
 TRUE., or WANTP = .FALSE. and one or both of NCOLB > 0

```

and WANTQ = .TRUE.

lrwork=5\*(min(M,N)-1)  
otherwise.

On exit: RWORK(min(M,N)) contains the total number of iterations taken by the QR algorithm.

The rest of the array is used as workspace.

- 16: CWORK(\*) -- COMPLEX(KIND(1.0D)) array Workspace  
Note: the length of CWORK must be at least max(1,lcwork),  
where lcwork must satisfy:

2

lcwork=N+max(N ,NCOLB) when  
M >= N and WANTQ and WANTP are both .TRUE.

2

lcwork=N+max(N +N,NCOLB) when  
M >= N and WANTQ = .TRUE., but WANTP = .FALSE.

lcwork=N+max(N,NCOLB) when  
M >= N and WANTQ = .FALSE.

2

lcwork=M +M when  
M < N and WANTP = .TRUE.

lcwork = M when  
M < N and WANTP = .FALSE.

- 17: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL=-1

One or more of the following conditions holds:

$M < 0$ ,

$N < 0$ ,

$LDA < M$ ,

$NCOLB < 0$ ,

$LDB < M$  and  $NCOLB > 0$ ,

$LDQ < M$  and  $M < N$  and  $WANTQ = .TRUE.$ ,

$LDPH < N$  and  $M \geq N$  and  $WANTQ = .TRUE.$  and  $WANTP = .TRUE.$ .

IFAIL > 0

The QR algorithm has failed to converge in  $50 \cdot \min(m, n)$  iterations. In this case  $SV(1)$ ,  $SV(2)$ , ...,  $SV(IFAIL)$  may not have been found correctly and the remaining singular values may not be the smallest. The matrix  $A$  will nevertheless have

$H$

been factorized as  $A = QEP$  where the leading  $\min(m, n)$  by  $\min(m, n)$  part of  $E$  is a bidiagonal matrix with  $SV(1)$ ,  $SV(2)$ , ...,  $SV(\min(m, n))$  as the diagonal elements and  $RWORK(1)$ ,  $RWORK(2)$ , ...,  $RWORK(\min(m, n)-1)$  as the super-diagonal elements.

This failure is not likely to occur.

## 7. Accuracy

The computed factors  $Q$ ,  $D$  and  $P$  satisfy the relation

$$QDP = A + E,$$

where

$$\|E\| \leq c(\text{epsilon}) \|A\|,$$

(epsilon) being the machine precision,  $c$  is a modest function of  $m$  and  $n$  and  $\|.\|$  denotes the spectral (two) norm. Note that  $\|A\| = sv$ .

## 8. Further Comments

Following the use of this routine the rank of A may be estimated by a call to the INTEGER FUNCTION F06KLF(\*). The statement:

```
IRANK = F06KLF(MIN(M, N), SV, 1, TOL)
```

returns the value (k-1) in IRANK, where k is the smallest integer for which  $SV(k) < tol * SV(1)$ , where tol is the tolerance supplied in TOL, so that IRANK is an estimate of the rank of S and thus also of A. If TOL is supplied as negative then the machine precision is used in place of TOL.

## 9. Example

## 9.1. Example 1

To find the singular value decomposition of the 5 by 3 matrix

```
(0.5i -0.5+1.5i -1.0+1.0i)
(0.4+0.3i 0.9+1.3i 0.2+1.4i)
A=(0.4 -0.4+0.4i 1.8)
(0.3-0.4i 0.1+0.7i 0.0)
(-0.3i 0.3+0.3i 2.4i)
```

H

together with the vector Q b for the vector

```
(-0.55+1.05i)
(0.49+0.93i)
b=(0.56-0.16i)
(0.39+0.23i)
(1.13+0.83i)
```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

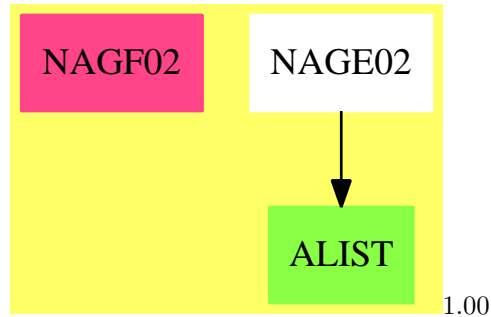

## 9.2. Example 2

To find the singular value decomposition of the 3 by 5 matrix

```
(0.5i 0.4-0.3i 0.4 0.3+0.4i 0.3i)
A=(-0.5-1.5i 0.9-1.3i -0.4-0.4i 0.1-0.7i 0.3-0.3i)
(-1.0-1.0i 0.2-1.4i 1.8 0.0 -2.4i)
```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

(package NAGF02 NagEigenPackage)≡
)abbrev package NAGF02 NagEigenPackage
++ Author: Godfrey Nolan and Mike Dewar
++ Date Created: Jan 1994
++ Date Last Updated: Thu May 12 17:45:20 1994
++ Description:
++ This package uses the NAG Library to compute
++ \begin{items}
++ \item eigenvalues and eigenvectors of a matrix
++ \item eigenvalues and eigenvectors of generalized matrix
++ eigenvalue problems
++ \item singular values and singular vectors of a matrix.
++ \end{items}
++ See \downlink{Manual Page}{manpageXXf02}.

```

 Integer,Integer,Integer,Integer) -> Result

```

```

++ f02axf(ar,iar,ai,iai,n,ivr,ivi,ifail)
++ calculates all the eigenvalues of a
++ complex Hermitian matrix.
++ See \downlink{Manual Page}{manpageXXf02axf}.
f02bbf : (Integer,Integer,DoubleFloat,DoubleFloat,
Integer,Integer,Matrix DoubleFloat,Integer) -> Result
++ f02bbf(ia,n,alb,ub,m,iv,a,ifail)
++ calculates selected eigenvalues of a real
++ symmetric matrix by reduction to tridiagonal form, bisection and
++ inverse iteration, where the selected eigenvalues lie within a
++ given interval.
++ See \downlink{Manual Page}{manpageXXf02bbf}.
f02bjf : (Integer,Integer,Integer,DoubleFloat,
Boolean,Integer,Matrix DoubleFloat,Matrix DoubleFloat,Integer) -> Result
++ f02bjf(n,ia,ib,eps1,matv,iv,a,b,ifail)
++ calculates all the eigenvalues and, if required, all the
++ eigenvectors of the generalized eigenproblem $Ax=(\lambda)Bx$
++ where A and B are real, square matrices, using the QZ algorithm.
++ See \downlink{Manual Page}{manpageXXf02bjf}.
f02fjf : (Integer,Integer,DoubleFloat,Integer,
Integer,Integer,Integer,Integer,Integer,Integer,Matrix DoubleFloat,Integer)
++ f02fjf(n,k,tol,novecs,nrx,lwork,lrwork,liwork,m,noits,x,ifail,dot,image)
++ finds eigenvalues of a real sparse symmetric
++ or generalized symmetric eigenvalue problem.
++ See \downlink{Manual Page}{manpageXXf02fjf}.
f02fjf : (Integer,Integer,DoubleFloat,Integer,
Integer,Integer,Integer,Integer,Integer,Integer,Matrix DoubleFloat,Integer)
++ f02fjf(n,k,tol,novecs,nrx,lwork,lrwork,liwork,m,noits,x,ifail,dot,image,m)
++ finds eigenvalues of a real sparse symmetric
++ or generalized symmetric eigenvalue problem.
++ See \downlink{Manual Page}{manpageXXf02fjf}.
f02wef : (Integer,Integer,Integer,Integer,
Integer,Boolean,Integer,Boolean,Integer,Matrix DoubleFloat,Matrix DoubleF
++ f02wef(m,n,lda,ncolb,ldb,wantq,ldq,wantp,ldpt,a,b,ifail)
++ returns all, or part, of the singular value decomposition
++ of a general real matrix.
++ See \downlink{Manual Page}{manpageXXf02wef}.
f02xef : (Integer,Integer,Integer,Integer,
Integer,Boolean,Integer,Boolean,Integer,Matrix Complex DoubleFloat,Matrix
++ f02xef(m,n,lda,ncolb,ldb,wantq,ldq,wantp,ldph,a,b,ifail)
++ returns all, or part, of the singular value decomposition
++ of a general complex matrix.
++ See \downlink{Manual Page}{manpageXXf02xef}.

#### 1. Scope of the Chapter

The main aim of this chapter is to assist the user in finding a function which approximates a set of data points. Typically the data contain random errors, as of experimental measurement, which need to be smoothed out. To seek an approximation to the data, it is first necessary to specify for the approximating function a mathematical form (a polynomial, for example) which contains a number of unspecified coefficients: the appropriate fitting routine then derives for the coefficients the values which provide the best fit of that particular form. The chapter deals mainly with curve and surface fitting (i.e., fitting with functions of one and of two variables) when a polynomial or a cubic spline is used as the fitting function, since these cover the most common needs. However, fitting with other functions and/or more variables can be undertaken by means of general

linear or nonlinear routines (some of which are contained in other chapters) depending on whether the coefficients in the function occur linearly or nonlinearly. Cases where a graph rather than a set of data points is given can be treated simply by first reading a suitable set of points from the graph.

The chapter also contains routines for evaluating, differentiating and integrating polynomial and spline curves and surfaces, once the numerical values of their coefficients have been determined.

## 2. Background to the Problems

### 2.1. Preliminary Considerations

In the curve-fitting problems considered in this chapter, we have a dependent variable  $y$  and an independent variable  $x$ , and we are given a set of data points  $(x_r, y_r)$ , for  $r=1,2,\dots,m$ . The

preliminary matters to be considered in this section will, for simplicity, be discussed in this context of curve-fitting problems. In fact, however, these considerations apply equally well to surface and higher-dimensional problems. Indeed, the discussion presented carries over essentially as it stands if, for these cases, we interpret  $x$  as a vector of several independent variables and correspondingly each  $x_r$  as a vector containing the  $r$ th data value of each independent variable.

We wish, then, to approximate the set of data points as closely as possible with a specified function,  $f(x)$  say, which is as smooth as possible --  $f(x)$  may, for example, be a polynomial. The requirements of smoothness and closeness conflict, however, and a balance has to be struck between them. Most often, the smoothness requirement is met simply by limiting the number of coefficients allowed in the fitting function -- for example, by restricting the degree in the case of a polynomial. Given a particular number of coefficients in the function in question, the fitting routines of this chapter determine the values of the coefficients such that the 'distance' of the function from the data points is as small as possible. The necessary balance is struck by the user comparing a selection of such fits having different numbers of coefficients. If the number of coefficients is too low, the approximation to the data will be poor. If the number is too high, the fit will be too close to the data, essentially following the random errors and tending to have unwanted

fluctuations between the data points. Between these extremes, there is often a group of fits all similarly close to the data points and then, particularly when least-squares polynomials are used, the choice is clear: it is the fit from this group having the smallest number of coefficients.

The above process can be seen as the user minimizing the smoothness measure (i.e., the number of coefficients) subject to the distance from the data points being acceptably small. Some of the routines, however, do this task themselves. They use a different measure of smoothness (in each case one that is continuous) and minimize it subject to the distance being less than a threshold specified by the user. This is a much more automatic process, requiring only some experimentation with the threshold.

#### 2.1.1. Fitting criteria: norms

A measure of the above 'distance' between the set of data points and the function  $f(x)$  is needed. The distance from a single data point  $(x_r, y_r)$  to the function can simply be taken as

$$(\text{epsilon})_r = y_r - f(x_r), \quad (1)$$

and is called the residual of the point. (With this definition, the residual is regarded as a function of the coefficients contained in  $f(x)$ ; however, the term is also used to mean the particular value of  $(\text{epsilon})_r$  which corresponds to the fitted

values of the coefficients.) However, we need a measure of distance for the set of data points as a whole. Three different measures are used in the different routines (which measure to select, according to circumstances, is discussed later in this sub-section). With  $(\text{epsilon})_r$  defined in (1), these measures, or

norms, are

$$\begin{aligned} & m \\ & \text{---} \\ & > |(\text{epsilon})_r|, \\ & \text{---} \quad r \\ & r=1 \end{aligned} \quad (2)$$

$$\sqrt[m]{\sum_{r=1}^{\infty} \epsilon_r^2} > (\epsilon), \text{ and} \quad (3)$$

$$\max_r |\epsilon_r|, \quad (4)$$

respectively the  $l_1$  norm, the  $l_2$  norm and the  $l_{\infty}$  norm.

Minimization of one or other of these norms usually provides the fitting criterion, the minimization being carried out with respect to the coefficients in the mathematical form used for  $f(x)$ : with respect to the  $b_i$  for example if the mathematical form

is the power series in (8) below. The fit which results from minimizing (2) is known as the  $l_1$  fit, or the fit in the  $l_1$  norm:

that which results from minimizing (3) is the  $l_2$  fit, the well-known least-squares fit (minimizing (3) is equivalent to minimizing the square of (3), i.e., the sum of squares of residuals, and it is the latter which is used in practice), and

that from minimizing (4) is the  $l_{\infty}$ , or minimax, fit.

Strictly speaking, implicit in the use of the above norms are the statistical assumptions that the random errors in the  $y_r$  are

independent of one another and that any errors in the  $x_r$  are

negligible by comparison. From this point of view, the use of the  $l_1$  norm is appropriate when the random errors in the  $y_r$  have a

normal distribution, and the  $l_{\infty}$  norm is appropriate when they

have a rectangular distribution, as when fitting a table of values rounded to a fixed number of decimal places. The  $l_1$  norm

is appropriate when the error distribution has its frequency function proportional to the negative exponential of the modulus of the normalised error -- not a common situation.

However, the user is often indifferent to these statistical considerations, and simply seeks a fit which he can assess by inspection, perhaps visually from a graph of the results. In this event, the  $l_1$  norm is particularly appropriate when the data are

thought to contain some 'wild' points (since fitting in this norm tends to be unaffected by the presence of a small number of such points), though of course in simple situations the user may prefer to identify and reject these points. The  $l_\infty$  norm

should be used only when the maximum residual is of particular concern, as may be the case for example when the data values have been obtained by accurate computation, as of a mathematical function. Generally, however, a routine based on least-squares should be preferred, as being computationally faster and usually providing more information on which to assess the results. In many problems the three fits will not differ significantly for practical purposes.

Some of the routines based on the  $l_2$  norm do not minimize the norm itself but instead minimize some (intuitively acceptable) measure of smoothness subject to the norm being less than a user-specified threshold. These routines fit with cubic or bicubic splines (see (10) and (14) below) and the smoothing measures relate to the size of the discontinuities in their third derivatives. A much more automatic fitting procedure follows from this approach.

#### 2.1.2. Weighting of data points

The use of the above norms also assumes that the data values  $y_r$  are of equal (absolute) accuracy. Some of the routines enable an allowance to be made to take account of differing accuracies. The allowance takes the form of 'weights' applied to the  $y$ -values so that those values known to be more accurate have a greater influence on the fit than others. These weights, to be supplied by the user, should be calculated from estimates of the absolute accuracies of the  $y$ -values, these estimates being expressed as standard deviations, probable errors or some other measure which has the same dimensions as  $y$ . Specifically, for each  $y_r$  the corresponding weight  $w_r$  should be inversely proportional to the accuracy estimate of  $y_r$ . For example, if the percentage accuracy

is the same for all  $y_r$ , then the absolute accuracy of  $y_r$  is proportional to  $y_r$  (assuming  $y_r$  to be positive, as it usually is in such cases) and so  $w_r = K/y_r$ , for  $r=1,2,\dots,m$ , for an arbitrary positive constant  $K$ . (This definition of weight is stressed because often weight is defined as the square of that used here.) The norms (2), (3) and (4) above are then replaced respectively by

$$\sum_{r=1}^m |w_r(\epsilon)|, \quad (5)$$

$$\sum_{r=1}^m w_r^2(\epsilon), \quad \text{and} \quad (6)$$

$$\max_r |w_r(\epsilon)|. \quad (7)$$

Again it is the square of (6) which is used in practice rather than (6) itself.

## 2.2. Curve Fitting

When, as is commonly the case, the mathematical form of the fitting function is immaterial to the problem, polynomials and cubic splines are to be preferred because their simplicity and ease of handling confer substantial benefits. The cubic spline is the more versatile of the two. It consists of a number of cubic polynomial segments joined end to end with continuity in first and second derivatives at the joins. The third derivative at the joins is in general discontinuous. The  $x$ -values of the joins are called knots, or, more precisely, interior knots. Their number determines the number of coefficients in the spline, just as the degree determines the number of coefficients in a polynomial.

## 2.2.1. Representation of polynomials

Rather than using the power-series form

$$f(x) = b_0 + b_1 x + b_2 x^2 + \dots + b_k x^k \quad (8)$$

to represent a polynomial, the routines in this chapter use the Chebyshev series form

$$f(x) = -a_{20} T_0(x) + a_{11} T_1(x) + a_{22} T_2(x) + \dots + a_{kk} T_k(x), \quad (9)$$

where  $T_i(x)$  is the Chebyshev polynomial of the first kind of degree  $i$  (see Cox and Hayes [1], page 9), and where the range of  $x$  has been normalised to run from  $-1$  to  $+1$ . The use of either form leads theoretically to the same fitted polynomial, but in practice results may differ substantially because of the effects of rounding error. The Chebyshev form is to be preferred, since it leads to much better accuracy in general, both in the computation of the coefficients and in the subsequent evaluation of the fitted polynomial at specified points. This form also has other advantages: for example, since the later terms in (9) generally decrease much more rapidly from left to right than do those in (8), the situation is more often encountered where the last terms are negligible and it is obvious that the degree of the polynomial can be reduced (note that on the interval  $-1 \leq x \leq 1$  for all  $i$ ,  $T_i(x)$  attains the value unity but never exceeds it, so that the coefficient  $a_i$  gives directly the maximum value of the term containing it).

## 2.2.2. Representation of cubic splines

A cubic spline is represented in the form

$$f(x) = c_{11} N_1(x) + c_{22} N_2(x) + \dots + c_{pp} N_p(x), \quad (10)$$

where  $N_i(x)$ , for  $i=1,2,\dots,p$ , is a normalised cubic B-spline (see Hayes [2]). This form, also, has advantages of computational

speed and accuracy over alternative representations.

### 2.3. Surface Fitting

There are now two independent variables, and we shall denote these by  $x$  and  $y$ . The dependent variable, which was denoted by  $y$  in the curve-fitting case, will now be denoted by  $f$ . (This is a rather different notation from that indicated for the general-dimensional problem in the first paragraph of Section 2.1, but it has some advantages in presentation.)

Again, in the absence of contrary indications in the particular application being considered, polynomials and splines are the approximating functions most commonly used. Only splines are used by the surface-fitting routines in this chapter.

#### 2.3.1. Bicubic splines: definition and representation

The bicubic spline is defined over a rectangle  $R$  in the  $(x,y)$  plane, the sides of  $R$  being parallel to the  $x$ - and  $y$ -axes.  $R$  is divided into rectangular panels, again by lines parallel to the axes. Over each panel the bicubic spline is a bicubic polynomial, that is it takes the form

$$\begin{array}{rcl} & \begin{array}{cc} 3 & 3 \\ \text{--} & \text{--} \end{array} & \begin{array}{c} i & j \\ & \end{array} \\ > & > & a \ x \ y . \\ & \begin{array}{cc} \text{--} & \text{--} \end{array} & ij \\ i=0 & j=0 & \end{array} \quad (13)$$

Each of these polynomials joins the polynomials in adjacent panels with continuity up to the second derivative. The constant  $x$ -values of the dividing lines parallel to the  $y$ -axis form the set of interior knots for the variable  $x$ , corresponding precisely to the set of interior knots of a cubic spline. Similarly, the constant  $y$ -values of dividing lines parallel to the  $x$ -axis form the set of interior knots for the variable  $y$ . Instead of representing the bicubic spline in terms of the above set of bicubic polynomials, however, it is represented, for the sake of computational speed and accuracy, in the form

$$\begin{array}{rcl} & \begin{array}{cc} p & q \\ \text{--} & \text{--} \end{array} & \\ f(x,y)= & > & > \ c \ M \ (x)N \ (y), \\ & \begin{array}{cc} \text{--} & \text{--} \end{array} & ij \ i \quad j \\ & i=1 & j=1 \end{array} \quad (14)$$

where  $M_i(x)$ , for  $i=1,2,\dots,p$ , and  $N_j(y)$ , for  $j=1,2,\dots,q$ , are normalised B-splines (see Hayes and Halliday [4] for further details of bicubic splines and Hayes [2] for normalised B-splines).

#### 2.4. General Linear and Nonlinear Fitting Functions

We have indicated earlier that, unless the data-fitting application under consideration specifically requires some other type of fitting function, a polynomial or a spline is usually to be preferred. Special routines for these functions, in one and in two variables, are provided in this chapter. When the application does specify some other fitting function, however, it may be treated by a routine which deals with a general linear function, or by one for a general nonlinear function, depending on whether the coefficients in the given function occur linearly or nonlinearly.

The general linear fitting function can be written in the form

$$f(x) = c_1(\phi_1(x)) + c_2(\phi_2(x)) + \dots + c_p(\phi_p(x)), \quad (15)$$

where  $x$  is a vector of one or more independent variables, and the  $(\phi_i)$  are any given functions of these variables (though they must be linearly independent of one another if there is to be the possibility of a unique solution to the fitting problem). This is not intended to imply that each  $(\phi_i)$  is necessarily a function of all the variables: we may have, for example, that each  $(\phi_i)$  is a function of a different single variable, and even that one of the  $(\phi_i)$  is a constant. All that is required is that a value of each  $(\phi_i)(x)$  can be computed when a value of each independent variable is given.

When the fitting function  $f(x)$  is not linear in its coefficients, no more specific representation is available in general than  $f(x)$  itself. However, we shall find it helpful later on to indicate the fact that  $f(x)$  contains a number of coefficients (to be determined by the fitting process) by using instead the notation

$f(x;c)$ , where  $c$  denotes the vector of coefficients. An example of a nonlinear fitting function is

$$f(x;c) = c_1 + c_2 \exp(-c_4 x) + c_3 \exp(-c_5 x), \quad (16)$$

which is in one variable and contains five coefficients. Note that here, as elsewhere in this Chapter Introduction, we use the term 'coefficients' to include all the quantities whose values are to be determined by the fitting process, not just those which occur linearly. We may observe that it is only the presence of the coefficients  $c_4$  and  $c_5$  which makes the form (16) nonlinear.

If the values of these two coefficients were known beforehand, (16) would instead be a linear function which, in terms of the general linear form (15), has  $p=3$  and

$$\begin{aligned} (\phi)_1(x) &= 1, & (\phi)_2(x) &= \exp(-c_4 x), & \text{and } (\phi)_3(x) &= \exp(-c_5 x). \\ &1 & &2 & &4 & &3 & &5 \end{aligned}$$

We may note also that polynomials and splines, such as (9) and (14), are themselves linear in their coefficients. Thus if, when fitting with these functions, a suitable special routine is not available (as when more than two independent variables are involved or when fitting in the  $l_1$  norm), it is appropriate to

use a routine designed for a general linear function.

## 2.5. Constrained Problems

So far, we have considered only fitting processes in which the values of the coefficients in the fitting function are determined by an unconstrained minimization of a particular norm. Some fitting problems, however, require that further restrictions be placed on the determination of the coefficient values. Sometimes these restrictions are contained explicitly in the formulation of the problem in the form of equalities or inequalities which the coefficients, or some function of them, must satisfy. For example, if the fitting function contains a term  $A \exp(-kx)$ , it may be required that  $k \geq 0$ . Often, however, the equality or inequality constraints relate to the value of the fitting function or its derivatives at specified values of the independent variable(s), but these too can be expressed in terms of the coefficients of the fitting function, and it is appropriate to do this if a general linear or nonlinear routine

is being used. For example, if the fitting function is that given in (10), the requirement that the first derivative of the function at  $x=x_0$  be non-negative can be expressed as

$$c_{11} N'_0(x) + c_{22} N'_0(x) + \dots + c_{pp} N'_0(x) \geq 0, \quad (17)$$

where the prime denotes differentiation with respect to  $x$  and each derivative is evaluated at  $x=x_0$ . On the other hand, if the requirement had been that the derivative at  $x=x_0$  be exactly zero, the inequality sign in (17) would be replaced by an equality.

Routines which provide a facility for minimizing the appropriate norm subject to such constraints are discussed in Section 3.6.

## 3. Recommendations on Choice and Use of Routines

### 3.1. General

The choice of a routine to treat a particular fitting problem will depend first of all on the fitting function and the norm to be used. Unless there is good reason to the contrary, the fitting function should be a polynomial or a cubic spline (in the

appropriate number of variables) and the norm should be the  $l_2$  norm (leading to the least-squares fit). If some other function is to be used, the choice of routine will depend on whether the function is nonlinear (in which case see Section 3.5.2) or linear in its coefficients (see Section 3.5.1), and, in the latter case, on whether the  $l_1$  or  $l_2$  norm is to be used. The latter section is appropriate for polynomials and splines, too, if the  $l_1$  norm is preferred.

In the case of a polynomial or cubic spline, if there is only one independent variable, the user should choose a spline (Section 3.3) when the curve represented by the data is of complicated form, perhaps with several peaks and troughs. When the curve is of simple form, first try a polynomial (see Section 3.2) of low degree, say up to degree 5 or 6, and then a spline if the polynomial fails to provide a satisfactory fit. (Of course, if third-derivative discontinuities are unacceptable to the user, a polynomial is the only choice.) If the problem is one of surface fitting, one of the spline routines should be used (Section 3.4). If the problem has more than two independent variables, it may be treated by the general linear routine in Section 3.5.1, again using a polynomial in the first instance.

Another factor which affects the choice of routine is the presence of constraints, as previously discussed in Section 2.5. Indeed this factor is likely to be overriding at present, because of the limited number of routines which have the necessary facility. See Section 3.6.

#### 3.1.1. Data considerations

A satisfactory fit cannot be expected by any means if the number and arrangement of the data points do not adequately represent the character of the underlying relationship: sharp changes in behaviour, in particular, such as sharp peaks, should be well covered. Data points should extend over the whole range of interest of the independent variable(s): extrapolation outside the data ranges is most unwise. Then, with polynomials, it is advantageous to have additional points near the ends of the ranges, to counteract the tendency of polynomials to develop fluctuations in these regions. When, with polynomial curves, the user can precisely choose the x-values of the data, the special points defined in Section 3.2.2 should be selected. With splines

the choice is less critical as long as the character of the relationship is adequately represented. All fits should be tested graphically before accepting them as satisfactory.

For this purpose it should be noted that it is not sufficient to plot the values of the fitted function only at the data values of the independent variable(s); at the least, its values at a similar number of intermediate points should also be plotted, as unwanted fluctuations may otherwise go undetected. Such fluctuations are the less likely to occur the lower the number of coefficients chosen in the fitting function. No firm guide can be given, but as a rough rule, at least initially, the number of coefficients should not exceed half the number of data points (points with equal or nearly equal values of the independent variable, or both independent variables in surface fitting, counting as a single point for this purpose). However, the situation may be such, particularly with a small number of data points, that a satisfactorily close fit to the data cannot be achieved without unwanted fluctuations occurring. In such cases, it is often possible to improve the situation by a transformation of one or more of the variables, as discussed in the next paragraph: otherwise it will be necessary to provide extra data points. Further advice on curve fitting is given in Cox and Hayes [1] and, for polynomials only, in Hayes [3] of Section 2.7. Much of the advice applies also to surface fitting; see also the Routine Documents.

### 3.1.2. Transformation of variables

Before starting the fitting, consideration should be given to the choice of a good form in which to deal with each of the variables: often it will be satisfactory to use the variables as they stand, but sometimes the use of the logarithm, square root, or some other function of a variable will lead to a better-behaved relationship. This question is customarily taken into account in preparing graphs and tables of a relationship and the same considerations apply when curve or surface fitting. The practical context will often give a guide. In general, it is best to avoid having to deal with a relationship whose behaviour in one region is radically different from that in another. A steep rise at the left-hand end of a curve, for example, can often best be treated by curve fitting in terms of  $\log(x+c)$  with some suitable value of the constant  $c$ . A case when such a transformation gave substantial benefit is discussed in Hayes [3] page 60. According to the features exhibited in any particular case, transformation of either dependent variable or independent

variable(s) or both may be beneficial. When there is a choice it is usually better to transform the independent variable(s): if the dependent variable is transformed, the weights attached to the data points must be adjusted. Thus (denoting the dependent variable by  $y$ , as in the notation for curves) if the  $y$  to be fitted have been obtained by a transformation  $y=g(Y)$  from original data values  $Y_r$ , with weights  $W_r$ , for  $r=1,2,\dots,m$ , we must take

$$w_r = W_r / (dy/dY), \quad (18)$$

where the derivative is evaluated at  $Y_r$ . Strictly, the transformation of  $Y$  and the adjustment of weights are valid only when the data errors in the  $Y_r$  are small compared with the range spanned by the  $Y_r$ , but this is usually the case.

### 3.2. Polynomial Curves

#### 3.2.1. Least-squares polynomials: arbitrary data points

E02ADF fits to arbitrary data points, with arbitrary weights, polynomials of all degrees up to a maximum degree  $k$ , which is at choice. If the user is seeking only a low degree polynomial, up to degree 5 or 6 say,  $k=10$  is an appropriate value, providing there are about 20 data points or more. To assist in deciding the degree of polynomial which satisfactorily fits the data, the routine provides the root-mean-square-residual  $s_i$  for all degrees  $i=1,2,\dots,k$ . In a satisfactory case, these  $s_i$  will decrease steadily as  $i$  increases and then settle down to a fairly constant value, as shown in the example

| $i$ | $s_i$  |
|-----|--------|
| 0   | 3.5215 |
| 1   | 0.7708 |

|    |        |
|----|--------|
| 2  | 0.1861 |
| 3  | 0.0820 |
| 4  | 0.0554 |
| 5  | 0.0251 |
| 6  | 0.0264 |
| 7  | 0.0280 |
| 8  | 0.0277 |
| 9  | 0.0297 |
| 10 | 0.0271 |

If the  $s_i$  values settle down in this way, it indicates that the closest polynomial approximation justified by the data has been achieved. The degree which first gives the approximately constant value of  $s_i$  (degree 5 in the example) is the appropriate degree

to select. (Users who are prepared to accept a fit higher than sixth degree, should simply find a high enough value of  $k$  to enable the type of behaviour indicated by the example to be detected: thus they should seek values of  $k$  for which at least 4 or 5 consecutive values of  $s_i$  are approximately the same.) If the

degree were allowed to go high enough,  $s_i$  would, in most cases, eventually start to decrease again, indicating that the data points are being fitted too closely and that undesirable fluctuations are developing between the points. In some cases, particularly with a small number of data points, this final decrease is not distinguishable from the initial decrease in  $s_i$ .

In such cases, users may seek an acceptable fit by examining the graphs of several of the polynomials obtained. Failing this, they may (a) seek a transformation of variables which improves the behaviour, (b) try fitting a spline, or (c) provide more data points. If data can be provided simply by drawing an approximating curve by hand and reading points from it, use the points discussed in Section 3.2.2.

### 3.2.2. Least-squares polynomials: selected data points

When users are at liberty to choose the  $x$ -values of data points, such as when the points are taken from a graph, it is most advantageous when fitting with polynomials to use the values  $x = \cos((\pi)r/n)$ , for  $r=0,1,\dots,n$  for some value of  $n$ , a suitable  $r$

value for which is discussed at the end of this section. Note that these  $x$  relate to the variable  $x$  after it has been

$r$   
normalised so that its range of interest is  $-1$  to  $+1$ . E02ADF may then be used as in Section 3.2.1 to seek a satisfactory fit.

## 3.3. Cubic Spline Curves

### 3.3.1. Least-squares cubic splines

E02BAF fits to arbitrary data points, with arbitrary weights, a cubic spline with interior knots specified by the user. The choice of these knots so as to give an acceptable fit must largely be a matter of trial and error, though with a little experience a satisfactory choice can often be made after one or two trials. It is usually best to start with a small number of knots (too many will result in unwanted fluctuations in the fit, or even in there being no unique solution) and, examining the fit graphically at each stage, to add a few knots at a time at places where the fit is particularly poor. Moving the existing knots towards these places will also often improve the fit. In regions where the behaviour of the curve underlying the data is changing rapidly, closer knots will be needed than elsewhere. Otherwise, positioning is not usually very critical and equally-spaced knots are often satisfactory. See also the next section, however.

A useful feature of the routine is that it can be used in applications which require the continuity to be less than the normal continuity of the cubic spline. For example, the fit may be required to have a discontinuous slope at some point in the range. This can be achieved by placing three coincident knots at the given point. Similarly a discontinuity in the second derivative at a point can be achieved by placing two knots there. Analogy with these discontinuous cases can provide guidance in more usual cases: for example, just as three coincident knots can produce a discontinuity in slope, so three close knots can produce a rapid change in slope. The closer the knots are, the more rapid can the change be.

Figure 1

Please see figure in printed Reference Manual

An example set of data is given in Figure 1. It is a rather tricky set, because of the scarcity of data on the right, but it will serve to illustrate some of the above points and to show some of the dangers to be avoided. Three interior knots (indicated by the vertical lines at the top of the diagram) are chosen as a start. We see that the resulting curve is not steep enough in the middle and fluctuates at both ends, severely on the right. The spline is unable to cope with the shape and more knots are needed.

In Figure 2, three knots have been added in the centre, where the data shows a rapid change in behaviour, and one further out at each end, where the fit is poor. The fit is still poor, so a further knot is added in this region and, in Figure 3, disaster ensues in rather spectacular fashion.

Figure 2

Please see figure in printed Reference Manual

Figure 3

Please see figure in printed Reference Manual

The reason is that, at the right-hand end, the fits in Figure 1 and Figure 2 have been interpreted as poor simply because of the fluctuations about the curve underlying the data (or what it is naturally assumed to be). But the fitting process knows only about the data and nothing else about the underlying curve, so it is important to consider only closeness to the data when deciding goodness of fit.

Thus, in Figure 1, the curve fits the last two data points quite well compared with the fit elsewhere, so no knot should have been added in this region. In Figure 2, the curve goes exactly through the last two points, so a further knot is certainly not needed here.

Figure 4

Please see figure in printed Reference Manual

Figure 4 shows what can be achieved without the extra knot on each of the flat regions. Remembering that within each knot interval the spline is a cubic polynomial, there is really no

need to have more than one knot interval covering each flat region.

What we have, in fact, in Figure 2 and Figure 3 is a case of too many knots (so too many coefficients in the spline equation) for the number of data points. The warning in the second paragraph of Section 2.1 was that the fit will then be too close to the data, tending to have unwanted fluctuations between the data points. The warning applies locally for splines, in the sense that, in localities where there are plenty of data points, there can be a lot of knots, as long as there are few knots where there are few points, especially near the ends of the interval. In the present example, with so few data points on the right, just the one extra knot in Figure 2 is too many! The signs are clearly present, with the last two points fitted exactly (at least to the graphical accuracy and actually much closer than that) and fluctuations within the last two knot-intervals (cf. Figure 1, where only the final point is fitted exactly and one of the wobbles spans several data points).

The situation in Figure 3 is different. The fit, if computed exactly, would still pass through the last two data points, with even more violent fluctuations. However, the problem has become so ill-conditioned that all accuracy has been lost. Indeed, if the last interior knot were moved a tiny amount to the right, there would be no unique solution and an error message would have been caused. Near-singularity is, sadly, not picked up by the routine, but can be spotted readily in a graph, as Figure 3. B-spline coefficients becoming large, with alternating signs, is another indication. However, it is better to avoid such situations, firstly by providing, whenever possible, data adequately covering the range of interest, and secondly by placing knots only where there is a reasonable amount of data.

The example here could, in fact, have utilised from the start the observation made in the second paragraph of this section, that three close knots can produce a rapid change in slope. The example has two such rapid changes and so requires two sets of three close knots (in fact, the two sets can be so close that one knot can serve in both sets, so only five knots prove sufficient in Figure 4). It should be noted, however, that the rapid turn occurs within the range spanned by the three knots. This is the reason that the six knots in Figure 2 are not satisfactory as they do not quite span the two turns.

Some more examples to illustrate the choice of knots are given in

Cox and Hayes [1].

### 3.3.2. Automatic fitting with cubic splines

E02BEF also fits cubic splines to arbitrary data points with arbitrary weights but itself chooses the number and positions of the knots. The user has to supply only a threshold for the sum of squares of residuals. The routine first builds up a knot set by a series of trial fits in the  $l_2$  norm. Then, with the knot set

2

decided, the final spline is computed to minimize a certain smoothing measure subject to satisfaction of the chosen threshold. Thus it is easier to use than E02BAF (see previous section), requiring only some experimentation with this threshold. It should therefore be first choice unless the user has a preference for the ordinary least-squares fit or, for example, wishes to experiment with knot positions, trying to keep their number down (E02BEF aims only to be reasonably frugal with knots).

## 3.4. Spline Surfaces

### 3.4.1. Least-squares bicubic splines

E02DAF fits to arbitrary data points, with arbitrary weights, a bicubic spline with its two sets of interior knots specified by the user. For choosing these knots, the advice given for cubic splines, in Section 3.3.1 above, applies here too. (See also the next section, however.) If changes in the behaviour of the surface underlying the data are more marked in the direction of one variable than of the other, more knots will be needed for the former variable than the latter. Note also that, in the surface case, the reduction in continuity caused by coincident knots will extend across the whole spline surface: for example, if three knots associated with the variable  $x$  are chosen to coincide at a value  $L$ , the spline surface will have a discontinuous slope across the whole extent of the line  $x=L$ .

With some sets of data and some choices of knots, the least-squares bicubic spline will not be unique. This will not occur, with a reasonable choice of knots, if the rectangle  $R$  is well covered with data points: here  $R$  is defined as the smallest rectangle in the  $(x,y)$  plane, with sides parallel to the axes, which contains all the data points. Where the least-squares solution is not unique, the minimal least-squares solution is computed, namely that least-squares solution which has the

smallest value of the sum of squares of the B-spline coefficients  $c_{ij}$  (see the end of Section 2.3.2 above). This choice of least-squares solution tends to minimize the risk of unwanted fluctuations in the fit. The fit will not be reliable, however, in regions where there are few or no data points.

#### 3.4.2. Automatic fitting with bicubic splines

E02DDF also fits bicubic splines to arbitrary data points with arbitrary weights but chooses the knot sets itself. The user has to supply only a threshold for the sum of squares of residuals. Just like the automatic curve E02BEF (Section 3.3.2), E02DDF then builds up the knot sets and finally fits a spline minimizing a smoothing measure subject to satisfaction of the threshold. Again, this easier to use routine is normally to be preferred, at least in the first instance.

E02DCF is a very similar routine to E02DDF but deals with data points of equal weight which lie on a rectangular mesh in the  $(x,y)$  plane. This kind of data allows a very much faster computation and so is to be preferred when applicable. Substantial departures from equal weighting can be ignored if the user is not concerned with statistical questions, though the quality of the fit will suffer if this is taken too far. In such cases, the user should revert to E02DDF.

### 3.5. General Linear and Nonlinear Fitting Functions

#### 3.5.1. General linear functions

For the general linear function (15), routines are available for fitting in the  $l_1$  and  $l_2$  norms. The least-squares routines (which are to be preferred unless there is good reason to use another norm -- see Section 2.1.1) are in Chapter F04. The  $l_1$  routine is E02GAF.

All the above routines are essentially linear algebra routines, and in considering their use we need to view the fitting process in a slightly different way from hitherto. Taking  $y$  to be the dependent variable and  $x$  the vector of independent variables, we have, as for equation (1) but with each  $x$  now a vector,

$r$

$$(\epsilon)_r = y_r - f(x)_r \quad r=1,2,\dots,m.$$

Substituting for  $f(x)$  the general linear form (15), we can write this as

$$c_1(\phi)_1(x)_r + c_2(\phi)_2(x)_r + \dots + c_p(\phi)_p(x)_r = y_r - (\epsilon)_r, \quad r=1,2,\dots,m \quad (19)$$

Thus we have a system of linear equations in the coefficients  $c_j$ .

Usually, in writing these equations, the  $(\epsilon)_r$  are omitted

and simply taken as implied. The system of equations is then described as an overdetermined system (since we must have  $m \geq p$  if there is to be the possibility of a unique solution to our fitting problem), and the fitting process of computing the  $c_j$  to

minimize one or other of the norms (2), (3) and (4) can be described, in relation to the system of equations, as solving the overdetermined system in that particular norm. In matrix notation, the system can be written as

$$(\Phi)c=y, \quad (20)$$

where  $(\Phi)$  is the  $m$  by  $p$  matrix whose element in row  $r$  and column  $j$  is  $(\phi)_j(x)_r$ , for  $r=1,2,\dots,m$ ;  $j=1,2,\dots,p$ . The vectors

$c$  and  $y$  respectively contain the coefficients  $c_j$  and the data values  $y_r$ .

The routines, however, use the standard notation of linear algebra, the overdetermined system of equations being denoted by

$$Ax=b \quad (21)$$

The correspondence between this notation and that which we have used for the data-fitting problem (equation (20)) is therefore given by

$$A=(\Phi), \quad x=c \quad b=y \quad (22)$$

Note that the norms used by these routines are the unweighted norms (2) and (3). If the user wishes to apply weights to the data points, that is to use the norms (5) or (6), the equivalences (22) should be replaced by

$$A=D(\Phi), \quad x=c \quad b=Dy$$

where  $D$  is a diagonal matrix with  $w_r$  as the  $r$ th diagonal element.

Here  $w_r$ , for  $r=1,2,\dots,m$ , is the weight of the  $r$ th data point as defined in Section 2.1.2.

### 3.5.2. Nonlinear functions

Routines for fitting with a nonlinear function in the  $l_2$  norm are provided in Chapter E04, and that chapter's Introduction should be consulted for the appropriate choice of routine. Again, however, the notation adopted is different from that we have used for data fitting. In the latter, we denote the fitting function by  $f(x;c)$ , where  $x$  is the vector of independent variables and  $c$  is the vector of coefficients, whose values are to be determined. The squared  $l_2$  norm, to be minimized with respect to the elements of  $c$ , is then

$$\begin{aligned} & \sum_{r=1}^m w_r^2 [y_r - f(x_r; c)]^2 \\ & > \sum_{r=1}^m w_r^2 [y_r - f(x_r; c)]^2 \end{aligned} \quad (23)$$

where  $y_r$  is the  $r$ th data value of the dependent variable,  $x_r$  is the vector containing the  $r$ th values of the independent variables, and  $w_r$  is the corresponding weight as defined in Section 2.1.2.

On the other hand, in the nonlinear least-squares routines of Chapter E04, the function to be minimized is denoted by

$$\begin{aligned} & \sum_{r=1}^m f^2(x_r), \\ & > \sum_{r=1}^m f^2(x_r), \end{aligned} \quad (24)$$

```
-- i
i=1
```

the minimization being carried out with respect to the elements of the vector  $x$ . The correspondence between the two notations is given by

$x=c$  and

$$f_i(x) = w_r [y_r - f(x; c)], \quad i=r=1, 2, \dots, m.$$

Note especially that the vector  $x$  of variables of the nonlinear least-squares routines is the vector  $c$  of coefficients of the data-fitting problem, and in particular that, if the selected routine requires derivatives of the  $f_i(x)$  to be provided, these

are derivatives of  $w_r [y_r - f(x; c)]$  with respect to the coefficients of the data-fitting problem.

### 3.6. Constraints

At present, there are only a limited number of routines which fit subject to constraints. Chapter E04 contains a routine, E04UCF, which can be used for fitting with a nonlinear function in the  $l_2$  norm subject to equality or inequality constraints. This routine, unlike those in that chapter suited to the unconstrained case, is not designed specifically for minimizing functions which are sums of squares, and so the function (23) has to be treated as a general nonlinear function. The E04 Chapter Introduction should be consulted.

The remaining constraint routine relates to fitting with polynomials in the  $l_2$  norm. E02AGF deals with polynomial curves

and allows precise values of the fitting function and (if required) all its derivatives up to a given order to be prescribed at one or more values of the independent variable.

### 3.7. Evaluation, Differentiation and Integration

Routines are available to evaluate, differentiate and integrate polynomials in Chebyshev-series form and cubic or bicubic splines in B-spline form. These polynomials and splines may have been

produced by the various fitting routines or, in the case of polynomials, from prior calls of the differentiation and integration routines themselves.

E02AEF and E02AKF evaluate polynomial curves: the latter has a longer parameter list but does not require the user to normalise the values of the independent variable and can accept coefficients which are not stored in contiguous locations. E02BBF evaluates cubic spline curves, and E02DEF and E02DFF bicubic spline surfaces.

Differentiation and integration of polynomial curves are carried out by E02AHF and E02AJF respectively. The results are provided in Chebyshev-series form and so repeated differentiation and integration are catered for. Values of the derivative or integral can then be computed using the appropriate evaluation routine.

For splines the differentiation and integration routines provided are of a different nature from those for polynomials. E02BCF provides values of a cubic spline curve and its first three derivatives (the rest, of course, are zero) at a given value of  $x$  spline over its whole range. These routines can also be applied to surfaces of the form (14). For example, if, for each value of  $j$  in turn, the coefficients  $c_{ij}$ , for  $i=1,2,\dots,p$  are supplied to

E02BCF with  $x=x_0$  and on each occasion we select from the output the value of the second derivative,  $d_j$  say, and if the whole set of  $d_j$  are then supplied to the same routine with  $x=y_0$ , the output will contain all the values at  $(x_0, y_0)$  of

$$\frac{d^2}{dx^2} f \quad \text{and} \quad \frac{d^{r+2}}{dx^2 dy^r} f, \quad r=1,2,3.$$

Equally, if after each of the first  $p$  calls of E02BCF we had selected the function value (E02BBF would also provide this) instead of the second derivative and we had supplied these values to E02BDF, the result obtained would have been the value of

$$\int_A^B |f(x,y)| dy,$$

where A and B are the end-points of the y interval over which the spline was defined.

E02 -- Curve and Surface Fitting E02ADF  
 E02ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

E02ADF computes weighted least-squares polynomial approximations to an arbitrary set of data points.

### 2. Specification

```

 SUBROUTINE E02ADF (M, KPLUS1, NROWS, X, Y, W, WORK1,
1 WORK2, A, S, IFAIL)
 INTEGER M, KPLUS1, NROWS, IFAIL
 DOUBLE PRECISION X(M), Y(M), W(M), WORK1(3*M), WORK2
1 (2*KPLUS1), A(NROWS,KPLUS1), S(KPLUS1)

```

### 3. Description

This routine determines least-squares polynomial approximations of degrees  $0, 1, \dots, k$  to the set of data points  $(x_r, y_r)$  with weights  $w_r$ , for  $r=1, 2, \dots, m$ .

The approximation of degree  $i$  has the property that it minimizes  $(\sigma_i)$  the sum of squares of the weighted residuals  $(\epsilon_r)$ , where

$$(\epsilon_r) = w_r (y_r - f_r)$$

and  $f_r$  is the value of the polynomial of degree  $i$  at the  $r$ th data point.

Each polynomial is represented in Chebyshev-series form with

normalised argument  $x$ . This argument lies in the range  $-1$  to  $+1$  and is related to the original variable  $x$  by the linear transformation

$$x = \frac{(2x_{\max} - x_{\min})}{(x_{\max} - x_{\min})}.$$

Here  $x_{\max}$  and  $x_{\min}$  are respectively the largest and smallest values of  $x$ . The polynomial approximation of degree  $i$  is represented as

$$-a_{i+1,1} T_1(x) + a_{i+1,2} T_2(x) + a_{i+1,3} T_3(x) + \dots + a_{i+1,i+1} T_{i+1}(x),$$

where  $T_j(x)$  is the Chebyshev polynomial of the first kind of degree  $j$  with argument  $(x)$ .

For  $i=0,1,\dots,k$ , the routine produces the values of  $a_{i+1,j+1}$ , for  $j=0,1,\dots,i$ , together with the value of the root mean square

$$\text{residual } s_i = \sqrt{\frac{1}{i+1} \sum_{j=0}^i a_{i+1,j+1}^2}.$$

In the case  $m=i+1$  the routine sets the value of  $s_i$  to zero.

The method employed is due to Forsythe [4] and is based upon the generation of a set of polynomials orthogonal with respect to summation over the normalised data set. The extensions due to Clenshaw [1] to represent these polynomials as well as the approximating polynomials in their Chebyshev-series forms are

incorporated. The modifications suggested by Reinsch and Gentleman (see [5]) to the method originally employed by Clenshaw for evaluating the orthogonal polynomials from their Chebyshev-series representations are used to give greater numerical stability.

For further details of the algorithm and its use see Cox [2] and [3].

Subsequent evaluation of the Chebyshev-series representations of the polynomial approximations should be carried out using E02AEF.

#### 5. Parameters

- 1: M -- INTEGER Input  
 On entry: the number m of data points. Constraint: M >= MDIST >= 2, where MDIST is the number of distinct x values in the data.
- 2: KPLUS1 -- INTEGER Input  
 On entry: k+1, where k is the maximum degree required.

Constraint:  $0 < \text{KPLUS1} \leq \text{MDIST}$ , where MDIST is the number of distinct  $x$  values in the data.

- 3: NROWS -- INTEGER Input  
 On entry:  
 the first dimension of the array A as declared in the (sub)program from which E02ADF is called.  
 Constraint:  $\text{NROWS} \geq \text{KPLUS1}$ .
- 4: X(M) -- DOUBLE PRECISION array Input  
 On entry: the values  $x_r$  of the independent variable, for  $r=1,2,\dots,m$ . Constraint: the values must be supplied in non-decreasing order with  $X(M) > X(1)$ .
- 5: Y(M) -- DOUBLE PRECISION array Input  
 On entry: the values  $y_r$  of the dependent variable, for  $r=1,2,\dots,m$ .
- 6: W(M) -- DOUBLE PRECISION array Input  
 On entry: the set of weights,  $w_r$ , for  $r=1,2,\dots,m$ . For advice on the choice of weights, see Section 2.1.2 of the Chapter Introduction. Constraint:  $W(r) > 0.0$ , for  $r=1,2,\dots,m$ .
- 7: WORK1(3\*M) -- DOUBLE PRECISION array Workspace
- 8: WORK2(2\*KPLUS1) -- DOUBLE PRECISION array Workspace
- 9: A(NROWS,KPLUS1) -- DOUBLE PRECISION array Output

On exit: the coefficients of  $T(x)$  in the approximating polynomial of degree  $i$ .  $A(i+1,j+1)$  contains the coefficient  $a_{i+1,j+1}$ , for  $i=0,1,\dots,k$ ;  $j=0,1,\dots,i$ .

- 10: S(KPLUS1) -- DOUBLE PRECISION array Output  
 On exit:  $S(i+1)$  contains the root mean square residual  $s_i$ , for  $i=0,1,\dots,k$ , as described in Section 3. For the interpretation of the values of the  $s_i$  and their use in selecting an appropriate degree, see Section 3.1 of the

## Chapter Introduction.

11: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 The weights are not all strictly positive.

IFAIL= 2  
 The values of  $X(r)$ , for  $r=1,2,\dots,M$  are not in non-decreasing order.

IFAIL= 3  
 All  $X(r)$  have the same value: thus the normalisation of  $X$  is not possible.

IFAIL= 4  
 On entry  $KPLUS1 < 1$  (so the maximum degree required is negative)  
 or  $KPLUS1 > MDIST$ , where  $MDIST$  is the number of distinct  $x$  values in the data (so there cannot be a unique solution for degree  $k=KPLUS1-1$ ).

IFAIL= 5  
 $NROWS < KPLUS1$ .

## 7. Accuracy

No error analysis for the method has been published. Practical experience with the method, however, is generally extremely satisfactory.

## 8. Further Comments

The time taken by the routine is approximately proportional to  $m(k+1)(k+11)$ .

The approximating polynomials may exhibit undesirable oscillations (particularly near the ends of the range) if the maximum degree  $k$  exceeds a critical value which depends on the number of data points  $m$  and their relative positions. As a rough guide, for equally-spaced data, this critical value is about

$2\sqrt{m}$ . For further details see Hayes [6] page 60.

#### 9. Example

Determine weighted least-squares polynomial approximations of degrees 0, 1, 2 and 3 to a set of 11 prescribed data points. For the approximation of degree 3, tabulate the data and the corresponding values of the approximating polynomial, together with the residual errors, and also the values of the approximating polynomial at points half-way between each pair of adjacent data points.

The example program supplied is written in a general form that will enable polynomial approximations of degrees 0,1,...,k to be obtained to  $m$  data points, with arbitrary positive weights, and the approximation of degree  $k$  to be tabulated. E02AEF is used to evaluate the approximating polynomial. The program is self-starting in that any number of data sets can be supplied.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E02 -- Curve and Surface Fitting

E02AEF

E02AEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

E02AEF evaluates a polynomial from its Chebyshev-series representation.

## 2. Specification

```

SUBROUTINE E02AEF (NPLUS1, A, XCAP, P, IFAIL)
INTEGER NPLUS1, IFAIL
DOUBLE PRECISION A(NPLUS1), XCAP, P

```

## 3. Description

This routine evaluates the polynomial

$$-a_0 T_0(x) + a_1 T_1(x) + a_2 T_2(x) + \dots + a_n T_n(x)$$

for any value of  $x$  satisfying  $-1 \leq x \leq 1$ . Here  $T_j(x)$  denotes the Chebyshev polynomial of the first kind of degree  $j$  with argument

$x$ . The value of  $n$  is prescribed by the user.

In practice, the variable  $x$  will usually have been obtained from an original variable  $x$ , where  $x_{\min} \leq x \leq x_{\max}$  and

$$x = \frac{((x_{\min} - x_{\max}) - (x_{\min} - x_{\max}))}{(x_{\max} - x_{\min})}$$

Note that this form of the transformation should be used computationally rather than the mathematical equivalent

$$x = \frac{(2x_{\min} - x_{\max})}{(x_{\max} - x_{\min})}$$

since the former guarantees that the computed value of  $x$  differs from its true value by at most  $4(\epsilon)$ , where  $(\epsilon)$  is the machine precision, whereas the latter has no such guarantee.

The method employed is based upon the three-term recurrence relation due to Clenshaw [1], with modifications to give greater numerical stability due to Reinsch and Gentleman (see [4]).

For further details of the algorithm and its use see Cox [2] and [3].

#### 4. References

- [3] Cox M G and Hayes J G (1973) Curve fitting: a guide and suite of algorithms for the non-specialist user. Report NAC26. National Physical Laboratory.
- [4] Gentlemen W M (1969) An Error Analysis of Goertzel's (Watt's) Method for Computing Fourier Coefficients. *Comput. J.* 12 160--165.

#### 5. Parameters

- 1: NPLUS1 -- INTEGER Input  
On entry: the number  $n+1$  of terms in the series (i.e., one greater than the degree of the polynomial). Constraint:  $NPLUS1 \geq 1$ .
- 2: A(NPLUS1) -- DOUBLE PRECISION array Input  
On entry:  $A(i)$  must be set to the value of the  $i$ th coefficient in the series, for  $i=1,2,\dots,n+1$ .
- 3: XCAP -- DOUBLE PRECISION Input

On entry:  $x$ , the argument at which the polynomial is to be evaluated. It should lie in the range  $-1$  to  $+1$ , but a value just outside this range is permitted (see Section 6) to allow for possible rounding errors committed in the

transformation from  $x$  to  $x$  discussed in Section 3. Provided the recommended form of the transformation is used, a successful exit is thus assured whenever the value of  $x$  lies in the range  $x_{\min}$  to  $x_{\max}$ .

4: P -- DOUBLE PRECISION Output  
On exit: the value of the polynomial.

5: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
ABS(XCAP) > 1.0 + 4(epsilon), where (epsilon) is the machine precision. In this case the value of P is set arbitrarily to zero.

IFAIL= 2  
On entry NPLUS1 < 1.

#### 7. Accuracy

The rounding errors committed are such that the computed value of the polynomial is exact for a slightly perturbed set of coefficients  $a_i + (\delta_i)a_i$ . The ratio of the sum of the absolute values of the  $(\delta_i)a_i$  to the sum of the absolute values of the  $a_i$  is less than a small multiple of  $(n+1)$  times machine precision.

#### 8. Further Comments

The time taken by the routine is approximately proportional to

$n+1$ .

It is expected that a common use of E02AEF will be the evaluation of the polynomial approximations produced by E02ADF and E02AFF(\*)

## 9. Example

Evaluate at 11 equally-spaced points in the interval  $-1 \leq x \leq 1$  the polynomial of degree 4 with Chebyshev coefficients, 2.0, 0.5, 0.25, 0.125, 0.0625.

The example program is written in a general form that will enable a polynomial of degree  $n$  in its Chebyshev-series form to be

evaluated at  $m$  equally-spaced points in the interval  $-1 \leq x \leq 1$ . The program is self-starting in that any number of data sets can be supplied.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

DOUBLE PRECISION XMIN, XMAX, X(M), Y(M), W(M), XF(MF), YF
1 (LYF), A(NROWS,KPLUS1), S(KPLUS1), WRK
2 (LWRK)

```

### 3. Description

This routine determines least-squares polynomial approximations of degrees up to  $k$  to the set of data points  $(x_r, y_r)$  with weights

$w_r$ , for  $r=1,2,\dots,m$ . The value of  $k$ , the maximum degree required, is prescribed by the user. At each of the values  $XF_r$ , for  $r =$

$1,2,\dots,MF$ , of the independent variable  $x$ , the approximations and their derivatives up to order  $p$  are constrained to have one of

the user-specified values  $YF_s$ , for  $s=1,2,\dots,n$ , where  $n=MF+1$   $p$   
 $r=1$

The approximation of degree  $i$  has the property that, subject to the imposed constraints, it minimizes  $(\text{Sigma})_i$ , the sum of the

squares of the weighted residuals  $(\text{epsilon})_r$  for  $r=1,2,\dots,m$  where

$$(\text{epsilon})_r = w_r (y_r - f_i(x_r))^2$$

and  $f_i(x_r)$  is the value of the polynomial approximation of degree  $i$  at the  $r$ th data point.

Each polynomial is represented in Chebyshev-series form with

normalised argument  $x$ . This argument lies in the range  $-1$  to  $+1$  and is related to the original variable  $x$  by the linear transformation

$$x = \frac{2x_{\max} - (x_{\max} + x_{\min})}{(x_{\max} - x_{\min})}$$

where  $x_{\min}$  and  $x_{\max}$ , specified by the user, are respectively the lower and upper end-points of the interval of  $x$  over which the polynomials are to be defined.

The polynomial approximation of degree  $i$  can be written as

$$-a_{i,0} + a_{i,1} T_1(x) + \dots + a_{i,j} T_j(x) + \dots + a_{i,i} T_i(x)$$

where  $T_j(x)$  is the Chebyshev polynomial of the first kind of degree  $j$  with argument  $x$ .

For  $i=n, n+1, \dots, k$ , the routine produces the values of the coefficients  $a_{i,j}$ , for  $j=0, 1, \dots, i$ , together with the value of the root mean square residual,  $S_i$ , defined as

$$S_i = \sqrt{\frac{1}{m' + n - i - 1} \sum_{j=1}^{m'} w_j^2}, \text{ where } m' \text{ is the number of data points with non-zero weight.}$$

Values of the approximations may subsequently be computed using E02AEF or E02AKF.

First E02AGF determines a polynomial  $(\mu)(x)$ , of degree  $n-1$ , which satisfies the given constraints, and a polynomial  $(\nu)(x)$ , of degree  $n$ , which has value (or derivative) zero wherever a

constrained value (or derivative) is specified. It then fits  $y_r - (\mu)_r(x_r)$ , for  $r=1,2,\dots,m$  with polynomials of the required

degree in  $x$  each with factor  $(\nu)_r(x_r)$ . Finally the coefficients of

$(\mu)_r(x_r)$  are added to the coefficients of these fits to give the coefficients of the constrained polynomial approximations to the data points  $(x_r, y_r)$ , for  $r=1,2,\dots,m$ . The method employed is

given in Hayes [3]: it is an extension of Forsythe's orthogonal polynomials method [2] as modified by Clenshaw [1].

#### 5. Parameters

- 1: M -- INTEGER Input  
On entry: the number  $m$  of data points to be fitted.  
Constraint:  $M \geq 1$ .
- 2: KPLUS1 -- INTEGER Input  
On entry:  $k+1$ , where  $k$  is the maximum degree required.  
Constraint:  $n+1 \leq KPLUS1 \leq m''+n$ , where  $n$  is the total number of constraints and  $m''$  is the number of data points with non-zero weights and distinct abscissae which do not coincide with any of the  $XF(r)$ .
- 3: NROWS -- INTEGER Input  
On entry:  
the first dimension of the array  $A$  as declared in the (sub)program from which E02AGF is called.  
Constraint:  $NROWS \geq KPLUS1$ .

- 4: XMIN -- DOUBLE PRECISION Input  
 5: XMAX -- DOUBLE PRECISION Input  
 On entry: the lower and upper end-points, respectively, of the interval  $[x_{\min}, x_{\max}]$ . Unless there are specific reasons to the contrary, it is recommended that XMIN and XMAX be set respectively to the lowest and highest value among the  $x_r$  and  $XF(r)$ . This avoids the danger of extrapolation provided there is a constraint point or data point with non-zero weight at each end-point. Constraint:  $XMAX > XMIN$ .
- 6: X(M) -- DOUBLE PRECISION array Input  
 On entry: the value  $x_r$  of the independent variable at the  $r$ th data point, for  $r=1,2,\dots,m$ . Constraint: the  $X(r)$  must be in non-decreasing order and satisfy  $XMIN \leq X(r) \leq XMAX$ .
- 7: Y(M) -- DOUBLE PRECISION array Input  
 On entry:  $Y(r)$  must contain  $y_r$ , the value of the dependent variable at the  $r$ th data point, for  $r=1,2,\dots,m$ .
- 8: W(M) -- DOUBLE PRECISION array Input  
 On entry: the weights  $w_r$  to be applied to the data points  $x_r$ , for  $r=1,2,\dots,m$ . For advice on the choice of weights see the Chapter Introduction. Negative weights are treated as positive. A zero weight causes the corresponding data point to be ignored. Zero weight should be given to any data point whose  $x$  and  $y$  values both coincide with those of a constraint (otherwise the denominators involved in the root-mean-square residuals  $s_i$  will be slightly in error).
- 9: MF -- INTEGER Input  
 On entry: the number of values of the independent variable at which a constraint is specified. Constraint:  $MF \geq 1$ .
- 10: XF(MF) -- DOUBLE PRECISION array Input  
 On entry: the  $r$ th value of the independent variable at which a constraint is specified, for  $r = 1,2,\dots,MF$ . Constraint: these values need not be ordered but must be

distinct and satisfy  $XMIN \leq XF(r) \leq XMAX$ .

- 11: YF(LYF) -- DOUBLE PRECISION array Input  
 On entry: the values which the approximating polynomials and their derivatives are required to take at the points specified in XF. For each value of XF(r), YF contains in successive elements the required value of the approximation, its first derivative, second derivative, ..., p<sup>th</sup> derivative, for  $r = 1, 2, \dots, MF$ . Thus the value which the kth derivative of each approximation ( $k=0$  referring to the approximation itself) is required to take at the point XF(r) must be contained in YF(s), where
- $$s = r + k + p_1 + p_2 + \dots + p_{r-1},$$
- for  $k=0, 1, \dots, p$  and  $r = 1, 2, \dots, MF$ . The derivatives are with respect to the user's variable x.
- 12: LYF -- INTEGER Input  
 On entry:  
 the dimension of the array YF as declared in the (sub)program from which E02AGF is called.  
 Constraint:  $LYF \geq n$ , where  $n = MF + p_1 + p_2 + \dots + p_{MF}$ .
- 13: IP(MF) -- INTEGER array Input  
 On entry: IP(r) must contain p<sub>r</sub>, the order of the highest-order derivative specified at XF(r), for  $r = 1, 2, \dots, MF$ .  
 $p_r = 0$  implies that the value of the approximation at XF(r) is specified, but not that of any derivative. Constraint:  $IP(r) \geq 0$ , for  $r=1, 2, \dots, MF$ .
- 14: A(NROWS, KPLUS1) -- DOUBLE PRECISION array Output  
 On exit: A(i+1, j+1) contains the coefficient a<sub>ij</sub> in the approximating polynomial of degree i, for  $i=n, n+1, \dots, k$ ;  $j=0, 1, \dots, i$ .
- 15: S(KPLUS1) -- DOUBLE PRECISION array Output  
 On exit: S(i+1) contains s<sub>i</sub>, for  $i=n, n+1, \dots, k$ , the root-mean-square residual corresponding to the approximating polynomial of degree i. In the case where the number of data

points with non-zero weight is equal to  $k+1-n$ ,  $s_i$  is indeterminate: the routine sets it to zero. For the interpretation of the values of  $s_i$  and their use in selecting an appropriate degree, see Section 3.1 of the Chapter Introduction.

- 16: NP1 -- INTEGER Output  
 On exit:  $n+1$ , where  $n$  is the total number of constraint conditions imposed:  $n = MF + p_1 + p_2 + \dots + p_{MF}$ .
- 17: WRK(LWRK) -- DOUBLE PRECISION array Output  
 On exit: WRK contains weighted residuals of the highest degree of fit determined ( $k$ ). The residual at  $x$  is in element  $2(n+1)+3(m+k+1)+r$ , for  $r=1,2,\dots,m$ . The rest of the array is used as workspace.
- 18: LWRK -- INTEGER Input  
 On entry:  
 the dimension of the array WRK as declared in the (sub)program from which E02AGF is called.  
 Constraint:  $LWRK \geq \max(4*M+3*KPLUS1, 8*n+5*IPMAX+MF+10)+2*n+2$ , where  $IPMAX = \max(IP(R))$ .
- 19: IWRK(LIWRK) -- INTEGER array Workspace
- 20: LIWRK -- INTEGER Input  
 On entry:  
 the dimension of the array IWRK as declared in the (sub)program from which E02AGF is called.  
 Constraint:  $LIWRK \geq 2*MF+2$ .
- 21: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 On entry  $M < 1$ ,  
 or  $KPLUS1 < n + 1$ ,  
 or  $NROWS < KPLUS1$ ,  
 or  $MF < 1$ ,  
 or  $LYF < n$ ,  
 or  $LWRK$  is too small (see Section 5),  
 or  $LIWRK < 2*MF+2$ .  
 (Here  $n$  is the total number of constraint conditions.)

IFAIL= 2  
 $IP(r) < 0$  for some  $r = 1, 2, \dots, MF$ .

IFAIL= 3  
 $XMIN \geq XMAX$ , or  $XF(r)$  is not in the interval  $XMIN$  to  $XMAX$   
 for some  $r = 1, 2, \dots, MF$ , or the  $XF(r)$  are not distinct.

IFAIL= 4  
 $X(r)$  is not in the interval  $XMIN$  to  $XMAX$  for some  
 $r=1, 2, \dots, M$ .

IFAIL= 5  
 $X(r) < X(r-1)$  for some  $r=2, 3, \dots, M$ .

IFAIL= 6  
 $KPLUS1 > m'' + n$ , where  $m''$  is the number of data points with  
 non-zero weight and distinct abscissae which do not coincide  
 with any  $XF(r)$ . Thus there is no unique solution.

IFAIL= 7  
 The polynomials  $(\mu)(x)$  and/or  $(\nu)(x)$  cannot be determined.  
 The problem supplied is too ill-conditioned. This may occur  
 when the constraint points are very close together, or large  
 in number, or when an attempt is made to constrain high-  
 order derivatives.

## 7. Accuracy

No complete error analysis exists for either the interpolating algorithm or the approximating algorithm. However, considerable

experience with the approximating algorithm shows that it is generally extremely satisfactory. Also the moderate number of constraints, of low order, which are typical of data fitting applications, are unlikely to cause difficulty with the interpolating routine.

#### 8. Further Comments

The time taken by the routine to form the interpolating

3

polynomial is approximately proportional to  $n^3$ , and that to form the approximating polynomials is very approximately proportional to  $m(k+1)(k+1-n)$ .

To carry out a least-squares polynomial fit without constraints, use E02ADF. To carry out polynomial interpolation only, use E01AEF(\*).

#### 9. Example

The example program reads data in the following order, using the notation of the parameter list above:

MF

IP(i), XF(i), Y-value and derivative values (if any) at XF(i), for  $i = 1, 2, \dots, MF$

M

X(i), Y(i), W(i), for  $i = 1, 2, \dots, M$

k, XMIN, XMAX

The output is:

the root-mean-square residual for each degree from n to k;

the Chebyshev coefficients for the fit of degree k;

the data points, and the fitted values and residuals for the fit of degree k.

The program is written in a generalized form which will read any number of data sets.

The data set supplied specifies 5 data points in the interval [0.0,4.0] with unit weights, to which are to be fitted polynomials,  $p$ , of degrees up to 4, subject to the 3 constraints:

$$p(0.0)=1.0, \quad p'(0.0)=-2.0, \quad p(4.0)=9.0.$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E02 -- Curve and Surface Fitting E02AHF  
 E02AHF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

E02AHF determines the coefficients in the Chebyshev-series representation of the derivative of a polynomial given in Chebyshev-series form.

### 2. Specification

```

 SUBROUTINE E02AHF (NP1, XMIN, XMAX, A, IA1, LA, PATM1,
1 ADIF, IADIF1, LADIF, IFAIL)
 INTEGER NP1, IA1, LA, IADIF1, LADIF, IFAIL
 DOUBLE PRECISION XMIN, XMAX, A(LA), PATM1, ADIF(LADIF)

```

### 3. Description

This routine forms the polynomial which is the derivative of a given polynomial. Both the original polynomial and its derivative are represented in Chebyshev-series form. Given the coefficients  $a_i$ , for  $i=0,1,\dots,n$ , of a polynomial  $p(x)$  of degree  $n$ , where

$$p(x) = -a_0 + a_1 T_1(x) + \dots + a_n T_n(x)$$

the routine returns the coefficients  $a_i$ , for  $i=0,1,\dots,n-1$ , of the polynomial  $q(x)$  of degree  $n-1$ , where

$$q(x) = \frac{dp(x)}{dx} = -a_0 + a_1 T_0(x) + \dots + a_{n-1} T_{n-1}(x).$$

Here  $T_j(x)$  denotes the Chebyshev polynomial of the first kind of degree  $j$  with argument  $x$ . It is assumed that the normalised

variable  $x$  in the interval  $[-1,+1]$  was obtained from the user's original variable  $x$  in the interval  $[x_{\min}, x_{\max}]$  by the linear transformation

$$x = \frac{2x_{\max} - (x_{\min} + x_{\max})}{x_{\max} - x_{\min}}$$

and that the user requires the derivative to be with respect to

the variable  $x$ . If the derivative with respect to  $x$  is required, set  $x_{\max} = 1$  and  $x_{\min} = -1$ .

Values of the derivative can subsequently be computed, from the coefficients obtained, by using E02AKF.

The method employed is that of [1] modified to obtain the

derivative with respect to  $x$ . Initially setting  $a_{n+1} = a_n = 0$ , the routine forms successively

$$a_i = a_{i-1} + \frac{2}{x_{\max} - x_{\min}} a_{i+1}, \quad i=n, n-1, \dots, 1.$$

## 4. References

- [1] Unknown (1961) Chebyshev-series. Modern Computing Methods, Chapter 8. NPL Notes on Applied Science (2nd Edition). 16 HMSO.

## 5. Parameters

1: NP1 -- INTEGER Input  
 On entry: n+1, where n is the degree of the given polynomial p(x). Thus NP1 is the number of coefficients in this polynomial. Constraint: NP1 >= 1.

2: XMIN -- DOUBLE PRECISION Input

3: XMAX -- DOUBLE PRECISION Input  
 On entry: the lower and upper end-points respectively of the interval  $[x_{\min}, x_{\max}]$ . The Chebyshev-series

representation is in terms of the normalised variable x, where

$$x = \frac{2x_{\max} - (x_{\max} + x_{\min})}{x_{\max} - x_{\min}}.$$

Constraint: XMAX > XMIN.

4: A(LA) -- DOUBLE PRECISION array Input  
 On entry: the Chebyshev coefficients of the polynomial p(x). Specifically, element 1 + i\*IA1 of A must contain the coefficient  $a_i$ , for i=0,1,...,n. Only these n+1 elements will be accessed.

Unchanged on exit, but see ADIF, below.

5: IA1 -- INTEGER Input  
 On entry: the index increment of A. Most frequently the

Chebyshev coefficients are stored in adjacent elements of A, and IA1 must be set to 1. However, if, for example, they are stored in A(1),A(4),A(7),..., then the value of IA1 must be 3. See also Section 8. Constraint: IA1  $\geq$  1.

6: LA -- INTEGER Input  
 On entry:  
 the dimension of the array A as declared in the (sub)program from which E02AHF is called.  
 Constraint: LA  $\geq$  1+(NP1-1)\*IA1.

7: PATM1 -- DOUBLE PRECISION Output  
 On exit: the value of  $p(x_{\min})$ . If this value is passed to the integration routine E02AJF with the coefficients of  $q(x)$ , then the original polynomial  $p(x)$  is recovered, including its constant coefficient.

8: ADIF(LADIF) -- DOUBLE PRECISION array Output  
 On exit: the Chebyshev coefficients of the derived polynomial  $q(x)$ . (The differentiation is with respect to the variable  $x$ ). Specifically, element 1+i\*IADIF1 of ADIF

contains the coefficient  $a_i$ ,  $i=0,1,\dots,n-1$ . Additionally element 1+n\*IADIF1 is set to zero. A call of the routine may have the array name ADIF the same as A, provided that note is taken of the order in which elements are overwritten, when choosing the starting elements and increments IA1 and IADIF1: i.e., the coefficients  $a_0, a_1, \dots, a_{i-1}$  must be intact

after coefficient  $a_i$  is stored. In particular, it is possible to overwrite the  $a_i$  completely by having IA1 = IADIF1, and the actual arrays for A and ADIF identical.

9: IADIF1 -- INTEGER Input  
 On entry: the index increment of ADIF. Most frequently the Chebyshev coefficients are required in adjacent elements of ADIF, and IADIF1 must be set to 1. However, if, for example, they are to be stored in ADIF(1),ADIF(4),ADIF(7),..., then the value of IADIF1 must be 3. See Section 8. Constraint:

IADIF1  $\geq$  1.

- 10: LADIF -- INTEGER Input  
 On entry:  
 the dimension of the array ADIF as declared in the  
 (sub)program from which E02AHF is called.  
 Constraint: LADIF  $\geq$  1 + (NP1-1)\*IADIF1.
- 11: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not  
 familiar with this parameter (described in the Essential  
 Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see  
 Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

On entry NP1 < 1,

or XMAX  $\leq$  XMIN,

or IA1 < 1,

or LA  $\leq$  (NP1-1)\*IA1,

or IADIF1 < 1,

or LADIF  $\leq$  (NP1-1)\*IADIF1.

#### 7. Accuracy

There is always a loss of precision in numerical differentiation, in this case associated with the multiplication by 2i in the formula quoted in Section 3.

#### 8. Further Comments

The time taken by the routine is approximately proportional to n+1.

The increments IA1, IADIF1 are included as parameters to give a degree of flexibility which, for example, allows a polynomial in

two variables to be differentiated with respect to either variable without rearranging the coefficients.

### 9. Example

Suppose a polynomial has been computed in Chebyshev-series form to fit data over the interval  $[-0.5, 2.5]$ . The example program evaluates the 1st and 2nd derivatives of this polynomial at 4 equally spaced points over the interval. (For the purposes of this example, XMIN, XMAX and the Chebyshev coefficients are simply supplied in DATA statements. Normally a program would first read in or generate data and compute the fitted polynomial.)

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

E02 -- Curve and Surface Fitting

E02AJF

E02AJF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

E02AJF determines the coefficients in the Chebyshev-series representation of the indefinite integral of a polynomial given in Chebyshev-series form.

### 2. Specification

```

 SUBROUTINE E02AJF (NP1, XMIN, XMAX, A, IA1, LA, QATM1,
1 AINT, IAIN1, LAINT, IFAIL)
 INTEGER NP1, IA1, LA, IAIN1, LAINT, IFAIL
 DOUBLE PRECISION XMIN, XMAX, A(LA), QATM1, AINT(LAINT)

```

### 3. Description

This routine forms the polynomial which is the indefinite integral of a given polynomial. Both the original polynomial and its integral are represented in Chebyshev-series form. If

supplied with the coefficients  $a_i$ , for  $i=0,1,\dots,n$ , of a polynomial  $p(x)$  of degree  $n$ , where

$$p(x) = \frac{1}{2} a_0 + a_1 T_1(x) + \dots + a_n T_n(x),$$

the routine returns the coefficients  $a'_i$ , for  $i=0,1,\dots,n+1$ , of the polynomial  $q(x)$  of degree  $n+1$ , where

$$q(x) = \frac{1}{2} a'_0 + a'_1 T_1(x) + \dots + a'_{n+1} T_{n+1}(x),$$

and

$$q(x) = \int p(x) dx.$$

Here  $T_j(x)$  denotes the Chebyshev polynomial of the first kind of degree  $j$  with argument  $x$ . It is assumed that the normalised

variable  $x$  in the interval  $[-1,+1]$  was obtained from the user's original variable  $x$  in the interval  $[x_{\min}, x_{\max}]$  by the linear transformation

$$x = \frac{2x_{\max} - (x_{\min} + x_{\max})}{x_{\max} - x_{\min}} - x_{\min}$$

and that the user requires the integral to be with respect to the

variable  $x$ . If the integral with respect to  $x$  is required, set  $x_{\min} = 1$  and  $x_{\max} = -1$ .

Values of the integral can subsequently be computed, from the coefficients obtained, by using E02AKF.

The method employed is that of Chebyshev-series [1] modified for integrating with respect to  $x$ . Initially taking  $a_{n+1} = a_{n+2} = 0$ , the routine forms successively

$$a'_i = \frac{a_{i-1} - a_{i+1}}{2i} * \frac{x_{\max} - x_{\min}}{2}, \quad i = n+1, n, \dots, 1.$$

The constant coefficient  $a'_0$  is chosen so that  $q(x)$  is equal to a specified value, QATM1, at the lower end-point of the interval on

which it is defined, i.e.,  $x = -1$ , which corresponds to  $x = x_{\min}$ .

#### 4. References

- [1] Unknown (1961) Chebyshev-series. Modern Computing Methods, Chapter 8. NPL Notes on Applied Science (2nd Edition). 16 HMSO.

#### 5. Parameters

- 1: NP1 -- INTEGER Input  
On entry:  $n+1$ , where  $n$  is the degree of the given polynomial  $p(x)$ . Thus NP1 is the number of coefficients in this polynomial. Constraint:  $NP1 \geq 1$ .
- 2: XMIN -- DOUBLE PRECISION Input
- 3: XMAX -- DOUBLE PRECISION Input  
On entry: the lower and upper end-points respectively of the interval  $[x_{\min}, x_{\max}]$ . The Chebyshev-series

representation is in terms of the normalised variable  $x$ , where

$$2x - (x_{\min} + x_{\max})$$

$$x = \frac{\max_{x \in [x_{\min}, x_{\max}]} p(x) - \min_{x \in [x_{\min}, x_{\max}]} p(x)}{\max_{x \in [x_{\min}, x_{\max}]} p(x) + \min_{x \in [x_{\min}, x_{\max}]} p(x)}$$

Constraint: XMAX > XMIN.

- 4: A(LA) -- DOUBLE PRECISION array Input  
 On entry: the Chebyshev coefficients of the polynomial  $p(x)$ . Specifically, element  $1+i*IA1$  of A must contain the coefficient  $a_i$ , for  $i=0,1,\dots,n$ . Only these  $n+1$  elements will be accessed.

Unchanged on exit, but see AINT, below.

- 5: IA1 -- INTEGER Input  
 On entry: the index increment of A. Most frequently the Chebyshev coefficients are stored in adjacent elements of A, and IA1 must be set to 1. However, if for example, they are stored in  $A(1), A(4), A(7), \dots$ , then the value of IA1 must be 3. See also Section 8. Constraint: IA1 >= 1.

- 6: LA -- INTEGER Input  
 On entry:  
 the dimension of the array A as declared in the (sub)program from which E02AJF is called.  
 Constraint: LA >= 1 + (NP1-1)\*IA1.

- 7: QATM1 -- DOUBLE PRECISION Input  
 On entry: the value that the integrated polynomial is required to have at the lower end-point of its interval of

definition, i.e., at  $x=-1$  which corresponds to  $x=x_{\min}$ . Thus, QATM1 is a constant of integration and will normally be set to zero by the user.

- 8: AINT(LAINT) -- DOUBLE PRECISION array Output  
 On exit: the Chebyshev coefficients of the integral  $q(x)$ . (The integration is with respect to the variable  $x$ , and the constant coefficient is chosen so that  $q(x_{\min})$  equals QATM1)  
 Specifically, element  $1+i*LAINT1$  of AINT contains the coefficient  $a'_i$ , for  $i=0,1,\dots,n+1$ . A call of the routine

may have the array name AINT the same as A, provided that note is taken of the order in which elements are overwritten when choosing starting elements and increments IA1 and IAIN1: i.e., the coefficients,  $a_0, a_1, \dots, a_{i-2}$  must be intact after coefficient  $a_i$  is stored. In particular it is possible to overwrite the  $a_i$  entirely by having IA1 = IAIN1, and the actual array for A and AINT identical.

9: IAIN1 -- INTEGER Input  
 On entry: the index increment of AINT. Most frequently the Chebyshev coefficients are required in adjacent elements of AINT, and IAIN1 must be set to 1. However, if, for example, they are to be stored in AINT(1), AINT(4), AINT(7), ..., then the value of IAIN1 must be 3. See also Section 8.  
 Constraint: IAIN1 >= 1.

10: LAINT -- INTEGER Input  
 On entry:  
 the dimension of the array AINT as declared in the (sub)program from which E02AJF is called.  
 Constraint: LAINT >= 1 + NP1 \* IAIN1.

11: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 On entry NP1 < 1,  
 or XMAX <= XMIN,  
 or IA1 < 1,  
 or LA <= (NP1-1)\*IA1,

```

or IAIN1 < 1,

or LAINT<=NP1*IAINT1.

```

#### 7. Accuracy

In general there is a gain in precision in numerical integration, in this case associated with the division by  $2i$  in the formula quoted in Section 3.

#### 8. Further Comments

The time taken by the routine is approximately proportional to  $n+1$ .

The increments  $IA1$ ,  $IAINT1$  are included as parameters to give a degree of flexibility which, for example, allows a polynomial in two variables to be integrated with respect to either variable without rearranging the coefficients.

#### 9. Example

Suppose a polynomial has been computed in Chebyshev-series form to fit data over the interval  $[-0.5, 2.5]$ . The example program evaluates the integral of the polynomial from 0.0 to 2.0. (For the purpose of this example,  $XMIN$ ,  $XMAX$  and the Chebyshev coefficients are simply supplied in `DATA` statements. Normally a program would read in or generate data and compute the fitted polynomial).

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

E02 -- Curve and Surface Fitting

E02AKF

E02AKF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

E02AKF evaluates a polynomial from its Chebyshev-series representation, allowing an arbitrary index increment for accessing the array of coefficients.

## 2. Specification

```

 SUBROUTINE E02AKF (NP1, XMIN, XMAX, A, IA1, LA, X, RESULT,
1 IFAIL)
 INTEGER NP1, IA1, LA, IFAIL
 DOUBLE PRECISION XMIN, XMAX, A(LA), X, RESULT

```

## 3. Description

If supplied with the coefficients  $a_i$ , for  $i=0,1,\dots,n$ , of a

polynomial  $p(x)$  of degree  $n$ , where

$$p(x) = -a_0 + a_1 T_1(x) + \dots + a_n T_n(x),$$

this routine returns the value of  $p(x)$  at a user-specified value

of the variable  $x$ . Here  $T_j(x)$  denotes the Chebyshev polynomial of

the first kind of degree  $j$  with argument  $x$ . It is assumed that

the independent variable  $x$  in the interval  $[-1,+1]$  was obtained from the user's original variable  $x$  in the interval  $[x_{\min}, x_{\max}]$

by the linear transformation

$$x = \frac{2x_{\max} - (x_{\max} + x_{\min})}{x_{\max} - x_{\min}}.$$

The coefficients  $a_i$  may be supplied in the array A, with any increment between the indices of array elements which contain successive coefficients. This enables the routine to be used in surface fitting and other applications, in which the array might have two or more dimensions.

The method employed is based upon the three-term recurrence relation due to Clenshaw [1], with modifications due to Reinsch and Gentleman (see [4]). For further details of the algorithm and its use see Cox [2] and Cox and Hayes [3].

#### 5. Parameters

1: NP1 -- INTEGER Input  
 On entry:  $n+1$ , where  $n$  is the degree of the given

polynomial  $p(x)$ . Constraint:  $NP1 \geq 1$ .

2: XMIN -- DOUBLE PRECISION Input

3: XMAX -- DOUBLE PRECISION Input  
 On entry: the lower and upper end-points respectively of the interval  $[x_{\min}, x_{\max}]$ . The Chebyshev-series

representation is in terms of the normalised variable  $x$ , where

$$x = \frac{2x - (x_{\max} + x_{\min})}{x_{\max} - x_{\min}}$$

Constraint: XMIN < XMAX.

- 4: A(LA) -- DOUBLE PRECISION array Input  
 On entry: the Chebyshev coefficients of the polynomial  $p(x)$ . Specifically, element  $1+i*IA1$  must contain the coefficient  $a_i$ , for  $i=0,1,\dots,n$ . Only these  $n+1$  elements will be accessed.
- 5: IA1 -- INTEGER Input  
 On entry: the index increment of A. Most frequently, the Chebyshev coefficients are stored in adjacent elements of A, and IA1 must be set to 1. However, if, for example, they are stored in  $A(1), A(4), A(7), \dots$ , then the value of IA1 must be 3. Constraint: IA1  $\geq 1$ .
- 6: LA -- INTEGER Input  
 On entry:  
 the dimension of the array A as declared in the (sub)program from which E02AKF is called.  
 Constraint: LA  $\geq (NP1-1)*IA1+1$ .
- 7: X -- DOUBLE PRECISION Input  
 On entry: the argument x at which the polynomial is to be evaluated. Constraint: XMIN  $\leq X \leq$  XMAX.
- 8: RESULT -- DOUBLE PRECISION Output  
  
 On exit: the value of the polynomial  $p(x)$ .
- 9: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

On entry NP1 < 1,

or IA1 < 1,

or LA<=(NP1-1)\*IA1,

or XMIN >= XMAX.

IFAIL= 2

X does not satisfy the restriction XMIN <= X <= XMAX.

#### 7. Accuracy

The rounding errors are such that the computed value of the polynomial is exact for a slightly perturbed set of coefficients  $a_i + (\delta a)_i$ . The ratio of the sum of the absolute values of the  $(\delta a)_i$  to the sum of the absolute values of the  $a_i$  is less than a small multiple of  $(n+1)$ \*machine precision.

#### 8. Further Comments

The time taken by the routine is approximately proportional to  $n+1$ .

#### 9. Example

Suppose a polynomial has been computed in Chebyshev-series form to fit data over the interval  $[-0.5, 2.5]$ . The example program evaluates the polynomial at 4 equally spaced points over the interval. (For the purposes of this example, XMIN, XMAX and the Chebyshev coefficients are supplied in DATA statements. Normally a program would first read in or generate data and compute the fitted polynomial.)

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

## E02BAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

E02BAF computes a weighted least-squares approximation to an arbitrary set of data points by a cubic spline with knots prescribed by the user. Cubic spline interpolation can also be carried out.

## 2. Specification

```

 SUBROUTINE E02BAF (M, NCAP7, X, Y, W, LAMDA, WORK1, WORK2,
1 C, SS, IFAIL)
 INTEGER M, NCAP7, IFAIL
 DOUBLE PRECISION X(M), Y(M), W(M), LAMDA(NCAP7), WORK1(M),
1 WORK2(4*NCAP7), C(NCAP7), SS

```

## 3. Description

This routine determines a least-squares cubic spline approximation  $s(x)$  to the set of data points  $(x_r, y_r)$  with weights  $w_r$

$w_r$ , for  $r=1,2,\dots,m$ . The value of  $NCAP7 = n+7$ , where  $n$  is the number of intervals of the spline (one greater than the number of interior knots), and the values of the knots  $(\lambda_5), (\lambda_6), \dots, (\lambda_{n+3})$ , interior to the data interval, are prescribed by the user.

$s(x)$  has the property that it minimizes  $(\theta)$ , the sum of squares of the weighted residuals  $(\epsilon_r)$ , for  $r=1,2,\dots,m$ , where

$$(\epsilon_r) = w_r (y_r - s(x_r)).$$

The routine produces this minimizing value of  $(\theta)$  and the

coefficients  $c_1, c_2, \dots, c_q$ , where  $q=n+3$ , in the B-spline representation

$$s(x) = \sum_{i=1}^q c_i N_i(x).$$

Here  $N_i(x)$  denotes the normalised B-spline of degree 3 defined upon the knots  $(\lambda)_i, (\lambda)_{i+1}, \dots, (\lambda)_{i+4}$ .

In order to define the full set of B-splines required, eight additional knots  $(\lambda)_1, (\lambda)_2, (\lambda)_3, (\lambda)_4, (\lambda)_{n+4}, (\lambda)_{n+5}, (\lambda)_{n+6}, (\lambda)_{n+7}$  are inserted automatically by the routine. The first four of these are set equal to the smallest  $x_r$  and the last four to the largest  $x_r$ .

The representation of  $s(x)$  in terms of B-splines is the most compact form possible in that only  $n+3$  coefficients, in addition to the  $n+7$  knots, fully define  $s(x)$ .

The method employed involves forming and then computing the least-squares solution of a set of  $m$  linear equations in the

coefficients  $c_i$  ( $i=1, 2, \dots, n+3$ ). The equations are formed using a recurrence relation for B-splines that is unconditionally stable (Cox [1], de Boor [5]), even for multiple (coincident) knots. The least-squares solution is also obtained in a stable manner by using orthogonal transformations, viz. a variant of Givens rotations (Gentleman [6] and [7]). This requires only one equation to be stored at a time. Full advantage is taken of the structure of the equations, there being at most four non-zero

values of  $N(x)$  for any value of  $x$  and hence at most four  
 $i$   
coefficients in each equation.

For further details of the algorithm and its use see Cox [2], [3] and [4].

Subsequent evaluation of  $s(x)$  from its B-spline representation may be carried out using E02BBF. If derivatives of  $s(x)$  are also required, E02BCF may be used. E02BDF can be used to compute the definite integral of  $s(x)$ .

#### 5. Parameters

1: M -- INTEGER

Input

On entry: the number  $m$  of data points. Constraint:  $M \geq \text{MDIST} + 4$ , where  $\text{MDIST}$  is the number of distinct  $x$  values in the data.

2: NCAP7 -- INTEGER Input

On entry:  $n+7$ , where  $n$  is the number of intervals of the spline (which is one greater than the number of interior knots, i.e., the knots strictly within the range  $x_1$  to  $x_m$ ) over which the spline is defined. Constraint:  $8 \leq \text{NCAP7} \leq \text{MDIST} + 4$ , where  $\text{MDIST}$  is the number of distinct  $x$  values in the data.

3: X(M) -- DOUBLE PRECISION array Input

On entry: the values  $x_r$  of the independent variable (abscissa), for  $r=1,2,\dots,m$ . Constraint:  $x_1 \leq x_2 \leq \dots \leq x_m$ .

4: Y(M) -- DOUBLE PRECISION array Input

On entry: the values  $y_r$  of the dependent variable (ordinate), for  $r=1,2,\dots,m$ .

5: W(M) -- DOUBLE PRECISION array Input

On entry: the values  $w_r$  of the weights, for  $r=1,2,\dots,m$ .

For advice on the choice of weights, see the Chapter Introduction. Constraint:  $W(r) > 0$ , for  $r=1,2,\dots,m$ .

6: LAMDA(NCAP7) -- DOUBLE PRECISION array Input/Output

On entry: LAMDA( $i$ ) must be set to the ( $i-4$ )th (interior)

knot, (lambda) <sub>$i$</sub> , for  $i=5,6,\dots,n+3$ . Constraint:  $X(1) < \text{LAMDA}(5) \leq \text{LAMDA}(6) \leq \dots \leq \text{LAMDA}(\text{NCAP7}-4) < X(M)$ . On exit: the input values are unchanged, and LAMDA( $i$ ), for  $i = 1, 2, 3, 4, \text{NCAP7}-3, \text{NCAP7}-2, \text{NCAP7}-1, \text{NCAP7}$  contains the additional (exterior) knots introduced by the routine. For advice on the choice of knots, see Section 3.3 of the Chapter Introduction.

7: WORK1(M) -- DOUBLE PRECISION array Workspace

```

9: C(NCAP7) -- DOUBLE PRECISION array Output
 On exit: the coefficient ci of the B-spline Ni(x), for
 i i

```

The conditions specified by Schoenberg and Whitney [8] fail

to hold for at least one subset of the distinct data abscissae. That is, there is no subset of NCAP7-4 strictly increasing values,  $X(R(1)), X(R(2)), \dots, X(R(\text{NCAP7-4}))$ , among the abscissae such that

$$X(R(1)) < \text{LAMDA}(1) < X(R(5)),$$

$$X(R(2)) < \text{LAMDA}(2) < X(R(6)),$$

...

$$X(R(\text{NCAP7-8})) < \text{LAMDA}(\text{NCAP7-8}) < X(R(\text{NCAP7-4})).$$

This means that there is no unique solution: there are regions containing too many knots compared with the number of data points.

### 7. Accuracy

The rounding errors committed are such that the computed coefficients are exact for a slightly perturbed set of ordinates  $y + (\delta)y$ . The ratio of the root-mean-square value for the

$\frac{r}{(\delta)y}$  to the root-mean-square value of the  $y$  can be expected

to be less than a small multiple of  $(\kappa) * m * \text{machine precision}$ , where  $(\kappa)$  is a condition number for the problem. Values of  $(\kappa)$  for 20-30 practical data sets all proved to lie between 4.5 and 7.8 (see Cox [3]). (Note that for these data sets, replacing the coincident end knots at the end-points  $x_1$  and  $x_m$

used in the routine by various choices of non-coincident exterior knots gave values of  $(\kappa)$  between 16 and 180. Again see Cox [3] for further details.) In general we would not expect  $(\kappa)$  to be large unless the choice of knots results in near-violation of the Schoenberg-Whitney conditions.

A cubic spline which adequately fits the data and is free from spurious oscillations is more likely to be obtained if the knots are chosen to be grouped more closely in regions where the function (underlying the data) or its derivatives change more rapidly than elsewhere.

### 8. Further Comments

The time taken by the routine is approximately  $C * (2m + n + 7)$

seconds, where  $C$  is a machine-dependent constant.

Multiple knots are permitted as long as their multiplicity does not exceed 4, i.e., the complete set of knots must satisfy

$(\lambda_i) < (\lambda_{i+4})$ , for  $i=1,2,\dots,n+3$ , (cf. Section 6). At a knot of multiplicity one (the usual case),  $s(x)$  and its first two derivatives are continuous. At a knot of multiplicity two,  $s(x)$  and its first derivative are continuous. At a knot of multiplicity three,  $s(x)$  is continuous, and at a knot of multiplicity four,  $s(x)$  is generally discontinuous.

The routine can be used efficiently for cubic spline

interpolation, i.e., if  $m=n+3$ . The abscissae must then of course satisfy  $x_1 < x_2 < \dots < x_m$ . Recommended values for the knots in this

case are  $(\lambda_i) = x_{i-2}$ , for  $i=5,6,\dots,n+3$ .

#### 9. Example

Determine a weighted least-squares cubic spline approximation with five intervals (four interior knots) to a set of 14 given data points. Tabulate the data and the corresponding values of the approximating spline, together with the residual errors, and also the values of the approximating spline at points half-way between each pair of adjacent data points.

The example program is written in a general form that will enable

a cubic spline approximation with  $n$  intervals ( $n-1$  interior knots) to be obtained to  $m$  data points, with arbitrary positive weights, and the approximation to be tabulated. Note that E02BBF is used to evaluate the approximating spline. The program is self-starting in that any number of data sets can be supplied.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

E02 -- Curve and Surface Fitting E02BBF  
 E02BBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

E02BBF evaluates a cubic spline from its B-spline representation.

### 2. Specification

```
SUBROUTINE E02BBF (NCAP7, LAMDA, C, X, S, IFAIL)
 INTEGER NCAP7, IFAIL
 DOUBLE PRECISION LAMDA(NCAP7), C(NCAP7), X, S
```

### 3. Description

This routine evaluates the cubic spline  $s(x)$  at a prescribed argument  $x$  from its augmented knot set  $(\lambda)_i$ , for

$i=1,2,\dots,n+7$ , (see E02BAF) and from the coefficients  $c_i$ , for  $i=1,2,\dots,q$  in its B-spline representation

$$s(x) = \sum_{i=1}^q c_i N_i(x)$$

Here  $q=n+3$ , where  $n$  is the number of intervals of the spline, and  $N_i(x)$  denotes the normalised B-spline of degree 3 defined upon the knots  $(\lambda)_i, (\lambda)_{i+1}, \dots, (\lambda)_{i+4}$ . The prescribed argument  $x$  must satisfy  $(\lambda)_i \leq x \leq (\lambda)_{i+4}$ .

4

n+4

It is assumed that  $(\lambda)_j \geq (\lambda)_{j-1}$ , for  $j=2,3,\dots,n+7$ , and  
 $(\lambda)_4 > (\lambda)_{n+4}$ .

The method employed is that of evaluation by taking convex combinations due to de Boor [4]. For further details of the algorithm and its use see Cox [1] and [3].

It is expected that a common use of E02BBF will be the evaluation of the cubic spline approximations produced by E02BAF. A generalization of E02BBF which also forms the derivative of  $s(x)$  is E02BCF. E02BCF takes about 50% longer than E02BBF.

#### 4. References

- [4] De Boor C (1972) On Calculating with B-splines. J. Approx. Theory. 6 50--62.

#### 5. Parameters

1: NCAP7 -- INTEGER

Input

On entry:  $n+7$ , where  $n$  is the number of intervals (one greater than the number of interior knots, i.e., the knots strictly within the range  $(\lambda)_4$  to  $(\lambda)_{n+4}$ ) over

which the spline is defined. Constraint: NCAP7  $\geq$  8.

- 2: LAMDA(NCAP7) -- DOUBLE PRECISION array Input  
 On entry: LAMDA(j) must be set to the value of the jth  
 member of the complete set of knots, (lambda) for  
j
- j=1,2,...,n+7. Constraint: the LAMDA(j) must be in non-  
 decreasing order with LAMDA(NCAP7-3) > LAMDA(4).
- 3: C(NCAP7) -- DOUBLE PRECISION array Input  
 On entry: the coefficient c of the B-spline N (x), for  
i
- i=1,2,...,n+3. The remaining elements of the array are not  
 used.
- 4: X -- DOUBLE PRECISION Input  
 On entry: the argument x at which the cubic spline is to be  
 evaluated. Constraint: LAMDA(4) <= X <= LAMDA(NCAP7-3).
- 5: S -- DOUBLE PRECISION Output  
 On exit: the value of the spline, s(x).
- 6: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not  
 familiar with this parameter (described in the Essential  
 Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see  
 Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

The argument X does not satisfy LAMDA(4) <= X <= LAMDA(NCAP7-3).

In this case the value of S is set arbitrarily to zero.

IFAIL= 2

NCAP7 < 8, i.e., the number of interior knots is negative.

## 7. Accuracy

The computed value of  $s(x)$  has negligible error in most practical situations. Specifically, this value has an absolute error bounded in modulus by  $18 * c_{\max} * \text{machine precision}$ , where  $c_{\max}$  is the largest in modulus of  $c_j, c_{j+1}, c_{j+2}$  and  $c_{j+3}$ , and  $j$  is an integer such that  $(\text{lambda})_j \leq x \leq (\text{lambda})_{j+3}$ . If  $c_{j+3}, c_{j+2}, c_{j+1}$  and  $c_j$  are all of the same sign, then the computed value of  $s(x)$  has a relative error not exceeding  $20 * \text{machine precision}$  in modulus. For further details see Cox [2].

#### 8. Further Comments

The time taken by the routine is approximately  $C * (1 + 0.1 * \log(n+7))$  seconds, where  $C$  is a machine-dependent constant.

Note: the routine does not test all the conditions on the knots given in the description of LAMDA in Section 5, since to do this would result in a computation time approximately linear in  $n+7$  instead of  $\log(n+7)$ . All the conditions are tested in E02BAF, however.

#### 9. Example

Evaluate at 9 equally-spaced points in the interval  $1.0 \leq x \leq 9.0$  the cubic spline with (augmented) knots 1.0, 1.0, 1.0, 1.0, 3.0, 6.0, 8.0, 9.0, 9.0, 9.0, 9.0 and normalised cubic B-spline coefficients 1.0, 2.0, 4.0, 7.0, 6.0, 4.0, 3.0.

The example program is written in a general form that will enable

a cubic spline with  $n$  intervals, in its normalised cubic B-spline form, to be evaluated at  $m$  equally-spaced points in the interval

$\text{LAMDA}(4) \leq x \leq \text{LAMDA}(n+4)$ . The program is self-starting in that any number of data sets may be supplied.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation

Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

E02 -- Curve and Surface Fitting E02BCF  
 E02BCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

E02BCF evaluates a cubic spline and its first three derivatives from its B-spline representation.

### 2. Specification

```
SUBROUTINE E02BCF (NCAP7, LAMDA, C, X, LEFT, S, IFAIL)
 INTEGER NCAP7, LEFT, IFAIL
 DOUBLE PRECISION LAMDA(NCAP7), C(NCAP7), X, S(4)
```

### 3. Description

This routine evaluates the cubic spline  $s(x)$  and its first three derivatives at a prescribed argument  $x$ . It is assumed that  $s(x)$  is represented in terms of its B-spline coefficients  $c_i$ , for

$i=1,2,\dots,n+3$  and (augmented) ordered knot set  $(\lambda_i)$ , for

$i=1,2,\dots,n+7$ , (see E02BAF), i.e.,

$$s(x) = \sum_{i=1}^q c_i N_i(x)$$

Here  $q=n+3$ ,  $n$  is the number of intervals of the spline and  $N_i(x)$

denotes the normalised B-spline of degree 3 (order 4) defined upon the knots  $(\lambda)_i, (\lambda)_{i+1}, \dots, (\lambda)_{i+4}$ . The prescribed argument  $x$  must satisfy

$$(\lambda)_i \leq x \leq (\lambda)_{i+4}$$

At a simple knot  $(\lambda)_i$  (i.e., one satisfying

$(\lambda)_{i-1} < (\lambda)_i < (\lambda)_{i+1}$ ), the third derivative of the spline is in general discontinuous. At a multiple knot (i.e., two or more knots with the same value), lower derivatives, and even the spline itself, may be discontinuous. Specifically, at a point  $x=u$  where (exactly)  $r$  knots coincide (such a point is termed a knot of multiplicity  $r$ ), the values of the derivatives of order

$4-j$ , for  $j=1,2,\dots,r$ , are in general discontinuous. (Here  $1 \leq r \leq 4$ ;  $r > 4$  is not meaningful.) The user must specify whether the value at such a point is required to be the left- or right-hand derivative.

The method employed is based upon:

- (i) carrying out a binary search for the knot interval containing the argument  $x$  (see Cox [3]),
- (ii) evaluating the non-zero B-splines of orders 1,2,3 and 4 by recurrence (see Cox [2] and [3]),
- (iii) computing all derivatives of the B-splines of order 4 by applying a second recurrence to these computed B-spline values (see de Boor [1]),
- (iv) multiplying the 4th-order B-spline values and their derivative by the appropriate B-spline coefficients, and summing, to yield the values of  $s(x)$  and its derivatives.

E02BCF can be used to compute the values and derivatives of cubic spline fits and interpolants produced by E02BAF.

If only values and not derivatives are required, E02BBF may be used instead of E02BCF, which takes about 50% longer than E02BBF.

- [3] Cox M G (1978) The Numerical Evaluation of a Spline from its B-spline Representation. J. Inst. Math. Appl. 21 135--143.

## 5. Parameters

1: NCAP7 -- INTEGER Input

On entry:  $n+7$ , where  $n$  is the number of intervals of the spline (which is one greater than the number of interior knots, i.e., the knots strictly within the range  $(\text{lambda})$

to  $(\text{lambda})$  over which the spline is defined).  
 $n+4$

Constraint: NCAP7  $\geq 8$ .

2: LAMDA(NCAP7) -- DOUBLE PRECISION array Input

On entry: LAMDA( $j$ ) must be set to the value of the  $j$ th member of the complete set of knots,  $(\text{lambda})$ , for  
 $j$

$j=1,2,\dots,n+7$ . Constraint: the LAMDA( $j$ ) must be in non-decreasing order with

LAMDA(NCAP7-3) > LAMDA(4).

3: C(NCAP7) -- DOUBLE PRECISION array Input

On entry: the coefficient  $c_i$  of the B-spline  $N(x)$ , for  
 $i$

$i=1,2,\dots,n+3$ . The remaining elements of the array are not used.

4: X -- DOUBLE PRECISION Input

On entry: the argument  $x$  at which the cubic spline and its derivatives are to be evaluated. Constraint: LAMDA(4)  $\leq X \leq$  LAMDA(NCAP7-3).

- 5: LEFT -- INTEGER Input  
 On entry: specifies whether left- or right-hand values of the spline and its derivatives are to be computed (see Section 3). Left- or right-hand values are formed according to whether LEFT is equal or not equal to 1. If x does not coincide with a knot, the value of LEFT is immaterial. If x = LAMDA(4), right-hand values are computed, and if x = LAMDA(NCAP7-3), left-hand values are formed, regardless of the value of LEFT.
- 6: S(4) -- DOUBLE PRECISION array Output  
 On exit: S(j) contains the value of the (j-1)th derivative of the spline at the argument x, for j = 1,2,3,4. Note that S(1) contains the value of the spline.
- 7: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

NCAP7 < 8, i.e., the number of intervals is not positive.

IFAIL= 2

Either LAMDA(4) >= LAMDA(NCAP7-3), i.e., the range over which s(x) is defined is null or negative in length, or X is an invalid argument, i.e., X < LAMDA(4) or X > LAMDA(NCAP7-3).

## 7. Accuracy

The computed value of s(x) has negligible error in most practical situations. Specifically, this value has an absolute error bounded in modulus by  $18 * c_{\max} * \text{machine precision}$ , where  $c_{\max}$  is

the largest in modulus of  $c_j, c_{j+1}, c_{j+2}$  and  $c_{j+3}$ , and j is an integer such that  $(\text{lambda})_{j+3} \leq x \leq (\text{lambda})_{j+4}$ . If  $c_j, c_{j+1}, c_{j+2}$

and  $c_{j+3}$  are all of the same sign, then the computed value of  $s(x)$  has relative error bounded by  $18 \times \text{machine precision}$ . For full details see Cox [3].

No complete error analysis is available for the computation of the derivatives of  $s(x)$ . However, for most practical purposes the absolute errors in the computed derivatives should be small.

#### 8. Further Comments

The time taken by this routine is approximately linear in

$\log(n+7)$ .

Note: the routine does not test all the conditions on the knots given in the description of LAMDA in Section 5, since to do this

would result in a computation time approximately linear in  $n+7$

instead of  $\log(n+7)$ . All the conditions are tested in E02BAF, however.

#### 9. Example

Compute, at the 7 arguments  $x = 0, 1, 2, 3, 4, 5, 6$ , the left- and right-hand values and first 3 derivatives of the cubic spline defined over the interval  $0 \leq x \leq 6$  having the 6 interior knots  $x = 1, 3, 3, 3, 4, 4$ , the 8 additional knots  $0, 0, 0, 0, 6, 6, 6, 6$ , and the 10 B-spline coefficients  $10, 12, 13, 15, 22, 26, 24, 18, 14, 12$ .

The input data items (using the notation of Section 5) comprise the following values in the order indicated:

|           |                                       |
|-----------|---------------------------------------|
| $n$       | $m$                                   |
| LAMDA(j), | for $j = 1, 2, \dots, \text{NCAP7}$   |
| C(j),     | for $j = 1, 2, \dots, \text{NCAP7}-4$ |

$x(i)$ ,            for  $i=1,2,\dots,m$

The example program is written in a general form that will enable the values and derivatives of a cubic spline having an arbitrary number of knots to be evaluated at a set of arbitrary points. Any number of data sets may be supplied. The only changes required to the program relate to the dimensions of the arrays LAMDA and C.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E02 -- Curve and Surface Fitting E02BDF  
           E02BDF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

E02BDF computes the definite integral of a cubic spline from its B-spline representation.

### 2. Specification

```
SUBROUTINE E02BDF (NCAP7, LAMDA, C, DEFINT, IFAIL)
 INTEGER NCAP7, IFAIL
 DOUBLE PRECISION LAMDA(NCAP7), C(NCAP7), DEFINT
```

### 3. Description

This routine computes the definite integral of the cubic spline  $s(x)$  between the limits  $x=a$  and  $x=b$ , where  $a$  and  $b$  are respectively the lower and upper limits of the range over which  $s(x)$  is defined. It is assumed that  $s(x)$  is represented in terms

of its B-spline coefficients  $c_i$ , for  $i=1,2,\dots,n+3$  and

(augmented) ordered knot set  $(\lambda_i)$ , for  $i=1,2,\dots,n+7$ , with

$$(\lambda)_i = a, \text{ for } i = 1, 2, 3, 4 \text{ and } (\lambda)_i = b, \text{ for } i$$

$i = n+4, n+5, n+6, n+7$ , (see E02BAF), i.e.,

$$s(x) = \sum_{i=1}^q c_i N_i(x).$$

Here  $q = n+3$ ,  $n$  is the number of intervals of the spline and  $N_i(x)$  denotes the normalised B-spline of degree 3 (order 4) defined upon the knots  $(\lambda)_i, (\lambda)_{i+1}, \dots, (\lambda)_{i+4}$ .

The method employed uses the formula given in Section 3 of Cox [1].

E02BDF can be used to determine the definite integrals of cubic spline fits and interpolants produced by E02BAF.

#### 4. References

- [1] Cox M G (1975) An Algorithm for Spline Interpolation. J. Inst. Math. Appl. 15 95--108.

#### 5. Parameters

1: NCAP7 -- INTEGER Input

On entry:  $n+7$ , where  $n$  is the number of intervals of the spline (which is one greater than the number of interior knots, i.e., the knots strictly within the range  $a$  to  $b$ ) over which the spline is defined. Constraint:  $NCAP7 \geq 8$ .

2: LAMDA(NCAP7) -- DOUBLE PRECISION array Input

On entry: LAMDA( $j$ ) must be set to the value of the  $j$ th member of the complete set of knots,  $(\lambda)_j$  for  $j$

$j=1,2,\dots,n+7$ . Constraint: the  $LAMDA(j)$  must be in non-decreasing order with  $LAMDA(NCAP7-3) > LAMDA(4)$  and satisfy  
 $LAMDA(1)=LAMDA(2)=LAMDA(3)=LAMDA(4)$   
 and

$LAMDA(NCAP7-3)=LAMDA(NCAP7-2)=LAMDA(NCAP7-1)=LAMDA(NCAP7)$ .

3: C(NCAP7) -- DOUBLE PRECISION array Input  
 On entry: the coefficient  $c_i$  of the B-spline  $N(x)$ , for  $i$

$i=1,2,\dots,n+3$ . The remaining elements of the array are not used.

4: DEFINT -- DOUBLE PRECISION Output  
 On exit: the value of the definite integral of  $s(x)$  between the limits  $x=a$  and  $x=b$ , where  $a=(lambda)_4$  and  $b=(lambda)_{n+4}$ .

5: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

$NCAP7 < 8$ , i.e., the number of intervals is not positive.

IFAIL= 2

At least one of the following restrictions on the knots is violated:

$LAMDA(NCAP7-3) > LAMDA(4)$ ,

$LAMDA(j) \geq LAMDA(j-1)$ ,

for  $j = 2, 3, \dots, \text{NCAP7}$ , with equality in the cases  
 $j=2, 3, 4, \text{NCAP7}-2, \text{NCAP7}-1$ , and  $\text{NCAP7}$ .

#### 7. Accuracy

The rounding errors are such that the computed value of the integral is exact for a slightly perturbed set of B-spline coefficients  $c_i$  differing in a relative sense from those supplied by no more than  $2.2 \cdot (n+3) \cdot \text{machine precision}$ .

#### 8. Further Comments

The time taken by the routine is approximately proportional to

$n+7$ .

#### 9. Example

Determine the definite integral over the interval  $0 \leq x \leq 6$  of a cubic spline having 6 interior knots at the positions  $(\text{lambda})=1, 3, 3, 3, 4, 4$ , the 8 additional knots  $0, 0, 0, 0, 6, 6, 6, 6$ , and the 10 B-spline coefficients  $10, 12, 13, 15, 22, 26, 24, 18, 14, 12$ .

The input data items (using the notation of Section 5) comprise the following values in the order indicated:

$n$

$\text{LAMDA}(j)$  for  $j = 1, 2, \dots, \text{NCAP7}$

,

$C(j)$ , for  $j = 1, 2, \dots, \text{NCAP7}-3$

The example program is written in a general form that will enable the definite integral of a cubic spline having an arbitrary number of knots to be computed. Any number of data sets may be supplied. The only changes required to the program relate to the dimensions of the arrays  $\text{LAMDA}$  and  $C$ .

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation

Library software and should be available on-line.

E02 -- Curve and Surface Fitting

E02BEF

E02BEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

E02BEF computes a cubic spline approximation to an arbitrary set of data points. The knots of the spline are located automatically, but a single parameter must be specified to control the trade-off between closeness of fit and smoothness of fit.

### 2. Specification

```

SUBROUTINE E02BEF (START, M, X, Y, W, S, NEST, N, LAMDA,
1 C, FP, WRK, LWRK, IWRK, IFAIL)
 INTEGER M, NEST, N, LWRK, IWRK(NEST), IFAIL
 DOUBLE PRECISION X(M), Y(M), W(M), S, LAMDA(NEST), C(NEST),
1 FP, WRK(LWRK)
 CHARACTER*1 START

```

### 3. Description

This routine determines a smooth cubic spline approximation  $s(x)$  to the set of data points  $(x_r, y_r)$ , with weights  $w_r$ , for  $r=1,2,\dots,m$ .

The spline is given in the B-spline representation

$$s(x) = \sum_{i=1}^{n-4} c_i N_i(x) \quad (1)$$

where  $N_i(x)$  denotes the normalised cubic B-spline defined upon  $i$

the knots  $(\lambda)_i, (\lambda)_{i+1}, \dots, (\lambda)_{i+4}$ .

The total number  $n$  of these knots and their values  $(\lambda)_1, \dots, (\lambda)_n$  are chosen automatically by the routine.

The knots  $(\lambda)_5, \dots, (\lambda)_{n-4}$  are the interior knots; they divide the approximation interval  $[x_1, x_m]$  into  $n-7$  sub-intervals.

The coefficients  $c_1, c_2, \dots, c_{n-4}$  are then determined as the solution of the following constrained minimization problem:

minimize

$$(\eta) = \sum_{i=5}^{n-4} (\delta)_i^2 \quad (2)$$

subject to the constraint

$$(\theta)_r = \sum_{r=1}^m (\epsilon)_r \leq S \quad (3)$$

where:  $(\delta)_i$  stands for the discontinuity jump in the third order derivative of  $s(x)$  at the interior knot  $(\lambda)_i$ ,

$(\epsilon)_r$  denotes the weighted residual  $w_r (y_r - s(x_r))$ ,

and  $S$  is a non-negative number to be specified by the user.

The quantity  $(\eta)$  can be seen as a measure of the (lack of) smoothness of  $s(x)$ , while closeness of fit is measured through  $(\theta)$ . By means of the parameter  $S$ , 'the smoothing factor', the user will then control the balance between these two (usually conflicting) properties. If  $S$  is too large, the spline will be

too smooth and signal will be lost (underfit); if  $S$  is too small, the spline will pick up too much noise (overfit). In the extreme cases the routine will return an interpolating spline ( $\theta=0$ ) if  $S$  is set to zero, and the weighted least-squares cubic polynomial ( $\eta=0$ ) if  $S$  is set very large. Experimenting with  $S$  values between these two extremes should result in a good compromise. (See Section 8.2 for advice on choice of  $S$ .)

The method employed is outlined in Section 8.3 and fully described in Dierckx [1], [2] and [3]. It involves an adaptive strategy for locating the knots of the cubic spline (depending on the function underlying the data and on the value of  $S$ ), and an iterative method for solving the constrained minimization problem once the knots have been determined.

Values of the computed spline, or of its derivatives or definite integral, can subsequently be computed by calling E02BBF, E02BCF or E02BDF, as described in Section 8.4.

#### 5. Parameters

1: START -- CHARACTER\*1 Input  
 On entry: START must be set to 'C' or 'W'.

If START = 'C' (Cold start), the routine will build up the knot set starting with no interior knots. No values need be assigned to the parameters N, LAMDA, WRK or IWRK.

If START = 'W' (Warm start), the routine will restart the

knot-placing strategy using the knots found in a previous call of the routine. In this case, the parameters N, LAMDA, WRK, and IWRK must be unchanged from that previous call. This warm start can save much time in searching for a satisfactory value of S. Constraint: START = 'C' or 'W'.

- 2: M -- INTEGER Input  
 On entry: m, the number of data points. Constraint: M ≥ 4.
  
- 3: X(M) -- DOUBLE PRECISION array Input  
 On entry: the values  $x_r$  of the independent variable  
 (abscissa)  $x$ , for  $r=1,2,\dots,m$ . Constraint:  $x_1 < x_2 < \dots < x_m$
  
- 4: Y(M) -- DOUBLE PRECISION array Input  
 On entry: the values  $y_r$  of the dependent variable  
 (ordinate)  $y$ , for  $r=1,2,\dots,m$ .
  
- 5: W(M) -- DOUBLE PRECISION array Input  
 On entry: the values  $w_r$  of the weights, for  $r=1,2,\dots,m$ .  
 For advice on the choice of weights, see the Chapter Introduction, Section 2.1.2. Constraint:  $W(r) > 0$ , for  $r=1,2,\dots,m$ .
  
- 6: S -- DOUBLE PRECISION Input  
 On entry: the smoothing factor, S.  
  
 If S=0.0, the routine returns an interpolating spline.  
  
 If S is smaller than machine precision, it is assumed equal to zero.  
  
 For advice on the choice of S, see Section 3 and Section 8.2  
 Constraint: S ≥ 0.0.
  
- 7: NEST -- INTEGER Input  
 On entry: an over-estimate for the number, n, of knots required. Constraint: NEST ≥ 8. In most practical situations, NEST = M/2 is sufficient. NEST never needs to be larger than M + 4, the number of knots needed for interpolation (S = 0.0).
  
- 8: N -- INTEGER Input/Output

On entry: if the warm start option is used, the value of  $N$  must be left unchanged from the previous call. On exit: the total number,  $n$ , of knots of the computed spline.

- 9: LAMDA(NEST) -- DOUBLE PRECISION array Input/Output  
 On entry: if the warm start option is used, the values LAMDA(1), LAMDA(2), ..., LAMDA(N) must be left unchanged from the previous call. On exit: the knots of the spline i.e., the positions of the interior knots LAMDA(5), LAMDA(6), ..., LAMDA(N-4) as well as the positions of the additional knots LAMDA(1) = LAMDA(2) = LAMDA(3) = LAMDA(4) =  $x_1$  and

$x_m$

LAMDA(N-3) = LAMDA(N-2) = LAMDA(N-1) = LAMDA(N) =  $x_m$  needed for the B-spline representation.

- 10: C(NEST) -- DOUBLE PRECISION array Output  
 On exit: the coefficient  $c_i$  of the B-spline  $N(x)$  in the spline approximation  $s(x)$ , for  $i=1,2,\dots,n-4$ .

- 11: FP -- DOUBLE PRECISION Output  
 On exit: the sum of the squared weighted residuals, (theta), of the computed spline approximation. If FP = 0.0, this is an interpolating spline. FP should equal S within a relative tolerance of 0.001 unless  $n=8$  when the spline has no interior knots and so is simply a cubic polynomial. For knots to be inserted, S must be set to a value below the value of FP produced in this case.

- 12: WRK(LWRK) -- DOUBLE PRECISION array Workspace  
 On entry: if the warm start option is used, the values WRK(1), ..., WRK(n) must be left unchanged from the previous call.

- 13: LWRK -- INTEGER Input  
 On entry:  
 the dimension of the array WRK as declared in the (sub)program from which E02BEF is called.  
 Constraint: LWRK  $\geq 4*M+16*NEST+41$ .

- 14: IWRK(NEST) -- INTEGER array Workspace  
 On entry: if the warm start option is used, the values IWRK(1), ..., IWRK(n) must be left unchanged from the previous call.

This array is used as workspace.

15: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry START /= 'C' or 'W',

or  $M < 4$ ,

or  $S < 0.0$ ,

or  $S = 0.0$  and  $NEST < M + 4$ ,

or  $NEST < 8$ ,

or  $LWRK < 4*M + 16*NEST + 41$ .

IFAIL= 2

The weights are not all strictly positive.

IFAIL= 3

The values of  $X(r)$ , for  $r=1,2,\dots,M$ , are not in strictly increasing order.

IFAIL= 4

The number of knots required is greater than NEST. Try increasing NEST and, if necessary, supplying larger arrays for the parameters LAMDA, C, WRK and IWRK. However, if NEST is already large, say  $NEST > M/2$ , then this error exit may indicate that S is too small.

IFAIL= 5

The iterative process used to compute the coefficients of the approximating spline has failed to converge. This error exit may occur if  $S$  has been set very small. If the error persists with increased  $S$ , consult NAG.

If  $IFAIL = 4$  or  $5$ , a spline approximation is returned, but it fails to satisfy the fitting criterion (see (2) and (3) in Section 3) - perhaps by only a small amount, however.

## 7. Accuracy

On successful exit, the approximation returned is such that its weighted sum of squared residuals  $FP$  is equal to the smoothing factor  $S$ , up to a specified relative tolerance of  $0.001$  - except that if  $n=8$ ,  $FP$  may be significantly less than  $S$ : in this case the computed spline is simply a weighted least-squares polynomial approximation of degree 3, i.e., a spline with no interior knots.

## 8. Further Comments

### 8.1. Timing

The time taken for a call of  $E02BEF$  depends on the complexity of the shape of the data, the value of the smoothing factor  $S$ , and the number of data points. If  $E02BEF$  is to be called for different values of  $S$ , much time can be saved by setting  $START =$

### 8.2. Choice of $S$

If the weights have been correctly chosen (see Section 2.1.2 of the Chapter Introduction), the standard deviation of  $w y_r$  would be the same for all  $r$ , equal to  $(\sigma_r)^2$ , say. In this case,

choosing the smoothing factor  $S$  in the range  $(\sigma_r)^2 (m \pm \sqrt{2m})$ , as suggested by Reinsch [4], is likely to give a good start in the search for a satisfactory value. Otherwise, experimenting with different values of  $S$  will be required from the start, taking account of the remarks in Section 3.

In that case, in view of computation time and memory requirements, it is recommended to start with a very large value for  $S$  and so determine the least-squares cubic polynomial; the value returned for  $FP$ , call it  $FP_0$ , gives an upper bound for  $S$ .

Then progressively decrease the value of  $S$  to obtain closer fits

- say by a factor of 10 in the beginning, i.e.,  $S = FP / 10$ ,  $S = FP$   
 $0$   $0$   
 $/100$ , and so on, and more carefully as the approximation shows more details.

The number of knots of the spline returned, and their location, generally depend on the value of  $S$  and on the behaviour of the function underlying the data. However, if E02BEF is called with  $START = 'W'$ , the knots returned may also depend on the smoothing factors of the previous calls. Therefore if, after a number of trials with different values of  $S$  and  $START = 'W'$ , a fit can finally be accepted as satisfactory, it may be worthwhile to call E02BEF once more with the selected value for  $S$  but now using  $START = 'C'$ . Often, E02BEF then returns an approximation with the same quality of fit but with fewer knots, which is therefore better if data reduction is also important.

### 8.3. Outline of Method Used

If  $S=0$ , the requisite number of knots is known in advance, i.e.,  $n=m+4$ ; the interior knots are located immediately as  $(\lambda)_i = x_i$ , for  $i=5,6,\dots,n-4$ . The corresponding least-squares spline  $i-2$  (see E02BAF) is then an interpolating spline and therefore a solution of the problem.

If  $S>0$ , a suitable knot set is built up in stages (starting with no interior knots in the case of a cold start but with the knot set found in a previous call if a warm start is chosen). At each stage, a spline is fitted to the data by least-squares (see E02BAF) and  $(\theta)$ , the weighted sum of squares of residuals, is computed. If  $(\theta)>S$ , new knots are added to the knot set to reduce  $(\theta)$  at the next stage. The new knots are located in intervals where the fit is particularly poor, their number depending on the value of  $S$  and on the progress made so far in reducing  $(\theta)$ . Sooner or later, we find that  $(\theta)\leq S$  and at that point the knot set is accepted. The routine then goes on to compute the (unique) spline which has this knot set and which satisfies the full fitting criterion specified by (2) and (3). The theoretical solution has  $(\theta)=S$ . The routine computes the spline by an iterative scheme which is ended when  $(\theta)=S$  within a relative tolerance of 0.001. The main part of each iteration consists of a linear least-squares computation of special form, done in a similarly stable and efficient manner as in E02BAF.

An exception occurs when the routine finds at the start that, even with no interior knots ( $n=8$ ), the least-squares spline already has its weighted sum of squares of residuals  $\leq S$ . In this case, since this spline (which is simply a cubic polynomial) also has an optimal value for the smoothness measure ( $\eta$ ), namely zero, it is returned at once as the (trivial) solution. It will usually mean that  $S$  has been chosen too large.

For further details of the algorithm and its use, see Dierckx [3]

#### 8.4. Evaluation of Computed Spline

The value of the computed spline at a given value  $X$  may be obtained in the double precision variable  $S$  by the call:

```
CALL E02BBF(N,LAMDA,C,X,S,IFAIL)
```

where  $N$ ,  $LAMDA$  and  $C$  are the output parameters of E02BEF.

The values of the spline and its first three derivatives at a given value  $X$  may be obtained in the double precision array  $SDIF$  of dimension at least 4 by the call:

```
CALL E02BCF(N,LAMDA,C,X,LEFT,SDIF,IFAIL)
```

where if  $LEFT = 1$ , left-hand derivatives are computed and if  $LEFT \neq 1$ , right-hand derivatives are calculated. The value of  $LEFT$  is only relevant if  $X$  is an interior knot.

The value of the definite integral of the spline over the interval  $X(1)$  to  $X(M)$  can be obtained in the double precision variable  $SINT$  by the call:

```
CALL E02BDF(N,LAMDA,C,SINT,IFAIL)
```

#### 9. Example

This example program reads in a set of data values, followed by a set of values of  $S$ . For each value of  $S$  it calls E02BEF to compute a spline approximation, and prints the values of the knots and the B-spline coefficients  $c$ .

i

The program includes code to evaluate the computed splines, by

calls to E02BBF, at the points  $x_r$  and at points mid-way between them. These values are not printed out, however; instead the results are illustrated by plots of the computed splines, together with the data points (indicated by \*) and the positions of the knots (indicated by vertical lines): the effect of decreasing  $S$  can be clearly seen. (The plots were obtained by calling NAG Graphical Supplement routine J06FAF(\*).)

Please see figures in printed Reference Manual

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E02 -- Curve and Surface Fitting E02DAF  
 E02DAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

E02DAF forms a minimal, weighted least-squares bicubic spline surface fit with prescribed knots to a given set of data points.

### 2. Specification

```

 SUBROUTINE E02DAF (M, PX, PY, X, Y, F, W, LAMDA, MU,
1 POINT, NPOINT, DL, C, NC, WS, NWS, EPS,
2 SIGMA, RANK, IFAIL)
 INTEGER M, PX, PY, POINT(NPOINT), NPOINT, NC, NWS,
1 RANK, IFAIL
 DOUBLE PRECISION X(M), Y(M), F(M), W(M), LAMDA(PX), MU(PY),
1 DL(NC), C(NC), WS(NWS), EPS, SIGMA

```

### 3. Description

This routine determines a bicubic spline fit  $s(x,y)$  to the set of data points  $(x_r, y_r, f_r)$  with weights  $w_r$ , for  $r=1,2,\dots,m$ . The two

sets of internal knots of the spline,  $\{(\lambda)\}$  and  $\{(\mu)\}$ , associated with the variables  $x$  and  $y$  respectively, are prescribed by the user. These knots can be thought of as dividing the data region of the  $(x,y)$  plane into panels (see diagram in Section 5). A bicubic spline consists of a separate bicubic polynomial in each panel, the polynomials joining together with continuity up to the second derivative across the panel boundaries.

$s(x,y)$  has the property that  $(\Sigma)$ , the sum of squares of its weighted residuals  $(\rho)$ , for  $r=1,2,\dots,m$ , where

$$(\rho)_r = w_r (s(x_r, y_r) - f_r), \quad (1)$$

is as small as possible for a bicubic spline with the given knot sets. The routine produces this minimized value of  $(\Sigma)$  and the coefficients  $c_{ij}$  in the B-spline representation of  $s(x,y)$  -

see Section 8. E02DEF and E02DFF are available to compute values of the fitted spline from the coefficients  $c_{ij}$ .

The least-squares criterion is not always sufficient to determine the bicubic spline uniquely: there may be a whole family of splines which have the same minimum sum of squares. In these cases, the routine selects from this family the spline for which the sum of squares of the coefficients  $c_{ij}$  is smallest: in other

words, the minimal least-squares solution. This choice, although arbitrary, reduces the risk of unwanted fluctuations in the spline fit. The method employed involves forming a system of  $m$  linear equations in the coefficients  $c_{ij}$  and then computing its

least-squares solution, which will be the minimal least-squares solution when appropriate. The basis of the method is described in Hayes and Halliday [4]. The matrix of the equation is formed using a recurrence relation for B-splines which is numerically stable (see Cox [1] and de Boor [2] - the former contains the more elementary derivation but, unlike [2], does not cover the case of coincident knots). The least-squares solution is also obtained in a stable manner by using orthogonal transformations, viz. a variant of Givens rotation (see Gentleman [3]). This requires only one row of the matrix to be stored at a time. Advantage is taken of the stepped-band structure which the matrix

possesses when the data points are suitably ordered, there being at most sixteen non-zero elements in any row because of the definition of B-splines. First the matrix is reduced to upper triangular form and then the diagonal elements of this triangle are examined in turn. When an element is encountered whose square, divided by the mean squared weight, is less than a threshold (epsilon), it is replaced by zero and the rest of the elements in its row are reduced to zero by rotations with the remaining rows. The rank of the system is taken to be the number of non-zero diagonal elements in the final triangle, and the non-zero rows of this triangle are used to compute the minimal least-squares solution. If all the diagonal elements are non-zero, the rank is equal to the number of coefficients  $c_{ij}$  and the solution

obtained is the ordinary least-squares solution, which is unique in this case.

#### 5. Parameters

- 1: M -- INTEGER Input  
On entry: the number of data points, m. Constraint: M > 1.
- 2: PX -- INTEGER Input
- 3: PY -- INTEGER Input  
On entry: the total number of knots (lambda) and (mu) associated with the variables x and y, respectively.  
Constraint: PX >= 8 and PY >= 8.

(They are such that PX-8 and PY-8 are the corresponding

numbers of interior knots.) The running time and storage required by the routine are both minimized if the axes are labelled so that PY is the smaller of PX and PY.

- 4: X(M) -- DOUBLE PRECISION array Input
- 5: Y(M) -- DOUBLE PRECISION array Input
- 6: F(M) -- DOUBLE PRECISION array Input  
 On entry: the co-ordinates of the data point  $(x_r, y_r, f_r)$ , for  $r=1,2,\dots,m$ . The order of the data points is immaterial, but see the array POINT, below.
- 7: W(M) -- DOUBLE PRECISION array Input  
 On entry: the weight  $w_r$  of the  $r$ th data point. It is important to note the definition of weight implied by the equation (1) in Section 3, since it is also common usage to define weight as the square of this weight. In this routine, each  $w_r$  should be chosen inversely proportional to the (absolute) accuracy of the corresponding  $f_r$ , as expressed, for example, by the standard deviation or probable error of the  $f_r$ . When the  $f_r$  are all of the same accuracy, all the  $w_r$  may be set equal to 1.0.
- 8: LAMDA(PX) -- DOUBLE PRECISION array Input/Output  
 On entry: LAMDA(i+4) must contain the  $i$ th interior knot ( $\lambda$ ) associated with the variable  $x$ , for  $i=1,2,\dots,PX-8$ . The knots must be in non-decreasing order and lie strictly within the range covered by the data values of  $x$ . A knot is a value of  $x$  at which the spline is allowed to be discontinuous in the third derivative with respect to  $x$ , though continuous up to the second derivative. This degree of continuity can be reduced, if the user requires, by the use of coincident knots, provided that no more than four knots are chosen to coincide at any point. Two, or three, coincident knots allow loss of continuity in, respectively, the second and first derivative with respect to  $x$  at the value of  $x$  at which they coincide. Four coincident knots split the spline surface into two independent parts. For choice of knots see Section 8. On

exit: the interior knots LAMDA(5) to LAMDA(PX-4) are unchanged, and the segments LAMDA(1:4) and LAMDA(PX-3:PX) contain additional (exterior) knots introduced by the routine in order to define the full set of B-splines required. The four knots in the first segment are all set equal to the lowest data value of x and the other four additional knots are all set equal to the highest value: there is experimental evidence that coincident end-knots are best for numerical accuracy. The complete array must be left undisturbed if E02DEF or E02DFF is to be used subsequently.

9: MU(PY) -- DOUBLE PRECISION array Input  
 On entry: MU(i+4) must contain the ith interior knot ( $\mu$ ) i+4  
 associated with the variable y,  $i=1,2,\dots,PY-8$ . The same remarks apply to MU as to LAMDA above, with Y replacing X, and y replacing x.

10: POINT(NPOINT) -- INTEGER array Input  
 On entry: indexing information usually provided by E02ZAF which enables the data points to be accessed in the order which produces the advantageous matrix structure mentioned in Section 3. This order is such that, if the (x,y) plane is thought of as being divided into rectangular panels by the two sets of knots, all data in a panel occur before data in succeeding panels, where the panels are numbered from bottom to top and then left to right with the usual arrangement of axes, as indicated in the diagram.

Please see figure in printed Reference Manual

A data point lying exactly on one or more panel sides is considered to be in the highest numbered panel adjacent to the point. E02ZAF should be called to obtain the array POINT, unless it is provided by other means.

11: NPOINT -- INTEGER Input  
 On entry:  
 the dimension of the array POINT as declared in the (sub)program from which E02DAF is called.  
 Constraint: NPOINT  $\geq M + (PX-7)*(PY-7)$ .

12: DL(NC) -- DOUBLE PRECISION array Output  
 On exit: DL gives the squares of the diagonal elements of the reduced triangular matrix, divided by the mean squared weight. It includes those elements, less than (epsilon),

which are treated as zero (see Section 3).

- 13: C(NC) -- DOUBLE PRECISION array Output  
 On exit: C gives the coefficients of the fit.  $C((PY-4)*(i-1)+j)$  is the coefficient  $c_{ij}$  of Section 3 and Section 8 for  $i=1,2,\dots,PX-4$  and  $j=1,2,\dots,PY-4$ . These coefficients are used by E02DEF or E02DFF to calculate values of the fitted function.
  
- 14: NC -- INTEGER Input  
 On entry: the value  $(PX-4)*(PY-4)$ .
  
- 15: WS(NWS) -- DOUBLE PRECISION array Workspace
  
- 16: NWS -- INTEGER Input  
 On entry:  
 the dimension of the array WS as declared in the (sub)program from which E02DAF is called.  
 Constraint:  $NWS \geq (2*NC+1)*(3*PY-6)-2$ .
  
- 17: EPS -- DOUBLE PRECISION Input  
 On entry: a threshold (epsilon) for determining the effective rank of the system of linear equations. The rank is determined as the number of elements of the array DL (see below) which are non-zero. An element of DL is regarded as zero if it is less than (epsilon). Machine precision is a suitable value for (epsilon) in most practical applications which have only 2 or 3 decimals accurate in data. If some coefficients of the fit prove to be very large compared with the data ordinates, this suggests that (epsilon) should be increased so as to decrease the rank. The array DL will give a guide to appropriate values of (epsilon) to achieve this, as well as to the choice of (epsilon) in other cases where some experimentation may be needed to determine a value which leads to a satisfactory fit.
  
- 18: SIGMA -- DOUBLE PRECISION Output  
 On exit: (Sigma), the weighted sum of squares of residuals. This is not computed from the individual residuals but from the right-hand sides of the orthogonally-transformed linear equations. For further details see Hayes and Halliday [4] page 97. The two methods of computation are theoretically equivalent, but the results may differ because of rounding error.

19: RANK -- INTEGER Output  
 On exit: the rank of the system as determined by the value of the threshold (epsilon). When RANK = NC, the least-squares solution is unique: in other cases the minimal least-squares solution is computed.

20: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 At least one set of knots is not in non-decreasing order, or an interior knot is outside the range of the data values.

IFAIL= 2  
 More than four knots coincide at a single point, possibly because all data points have the same value of x (or y) or because an interior knot coincides with an extreme data value.

IFAIL= 3  
 Array POINT does not indicate the data points in panel order. Call E02ZAF to obtain a correct array.

IFAIL= 4  
 On entry M <= 1,  
 or PX < 8,  
 or PY < 8,  
 or NC /= (PX-4)\*(PY-4),  
 or NWS is too small,  
 or NPOINT is too small.

IFAIL= 5

All the weights  $w_r$  are zero or rank determined as zero.

### 7. Accuracy

The computation of the B-splines and reduction of the observation matrix to triangular form are both numerically stable.

### 8. Further Comments

The time taken by this routine is approximately proportional to  $m^2$  the number of data points,  $m$ , and to  $(3*(PY-4)+4)$ .

The B-spline representation of the bicubic spline is

$$s(x,y) = \sum_{i,j} c_{ij} M_i(x) N_j(y)$$

summed over  $i=1,2,\dots,PX-4$  and over  $j=1,2,\dots,PY-4$ . Here  $M_i(x)$  and  $N_j(y)$  denote normalised cubic B-splines, the former defined on the knots  $(\lambda_i), (\lambda_{i+1}), \dots, (\lambda_{i+4})$  and the latter on the knots  $(\mu_j), (\mu_{j+1}), \dots, (\mu_{j+4})$ . For further details, see Hayes and Halliday [4] for bicubic splines and de Boor [2] for normalised B-splines.

The choice of the interior knots, which help to determine the spline's shape, must largely be a matter of trial and error. It is usually best to start with a small number of knots and, examining the fit at each stage, add a few knots at a time at places where the fit is particularly poor. In intervals of  $x$  or  $y$  where the surface represented by the data changes rapidly, in function value or derivatives, more knots will be needed than elsewhere. In some cases guidance can be obtained by analogy with the case of coincident knots: for example, just as three coincident knots can produce a discontinuity in slope, three close knots can produce rapid change in slope. Of course, such rapid changes in behaviour must be adequately represented by the data points, as indeed must the behaviour of the surface generally, if a satisfactory fit is to be achieved. When there is

no rapid change in behaviour, equally-spaced knots will often suffice.

In all cases the fit should be examined graphically before it is accepted as satisfactory.

The fit obtained is not defined outside the rectangle

$$\begin{array}{ccccc} (\text{lambda}) <= x <= (\text{lambda}) & , & (\mu) <= y <= (\mu) \\ 4 & & \text{PX-3} & & 4 \quad \text{PY-3} \end{array}$$

The reason for taking the extreme data values of  $x$  and  $y$  for these four knots is that, as is usual in data fitting, the fit cannot be expected to give satisfactory values outside the data region. If, nevertheless, the user requires values over a larger rectangle, this can be achieved by augmenting the data with two artificial data points  $(a, c, 0)$  and  $(b, d, 0)$  with zero weight, where  $a <= x <= b$ ,  $c <= y <= d$  defines the enlarged rectangle. In the case when the data are adequate to make the least-squares solution unique ( $\text{RANK} = \text{NC}$ ), this enlargement will not affect the fit over the original rectangle, except for possibly enlarged rounding errors, and will simply continue the bicubic polynomials in the panels bordering the rectangle out to the new boundaries: in other cases the fit will be affected. Even using the original rectangle there may be regions within it, particularly at its corners, which lie outside the data region and where, therefore, the fit will be unreliable. For example, if there is no data point in panel 1 of the diagram in Section 5, the least-squares criterion leaves the spline indeterminate in this panel: the minimal spline determined by the subroutine in this case passes through the value zero at the point  $((\text{lambda}) , (\mu) )$ .

4      4

#### 9. Example

This example program reads a value for  $(\epsilon)$ , and a set of data points, weights and knot positions. If there are more  $y$  knots than  $x$  knots, it interchanges the  $x$  and  $y$  axes. It calls E02ZAF to sort the data points into panel order, E02DAF to fit a bicubic spline to them, and E02DEF to evaluate the spline at the data points.

Finally it prints:

the weighted sum of squares of residuals computed from the linear equations;

the rank determined by E02DAF;  
 data points, fitted values and residuals in panel order;  
 the weighted sum of squares of the residuals;  
 the coefficients of the spline fit.

The program is written to handle any number of data sets.

Note: the data supplied in this example is not typical of a realistic problem: the number of data points would normally be much larger (in which case the array dimensions and the value of NWS in the program would have to be increased); and the value of (epsilon) would normally be much smaller on most machines (see

-6

Section 5; the relatively large value of 10 has been chosen in order to illustrate a minimal least-squares solution when RANK < NC; in this example NC = 24).

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E02 -- Curve and Surface Fitting

E02DCF

E02DCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

E02DCF computes a bicubic spline approximation to a set of data values, given on a rectangular grid in the x-y plane. The knots of the spline are located automatically, but a single parameter must be specified to control the trade-off between closeness of fit and smoothness of fit.

#### 2. Specification

SUBROUTINE E02DCF (START, MX, X, MY, Y, F, S, NXEST,

```

1 NYEST, NX, LAMDA, NY, MU, C, FP, WRK,
2 LWRK, IWRK, LIWRK, IFAIL)
 INTEGER MX, MY, NXEST, NYEST, NX, NY, LWRK, IWRK
1 (LIWRK), LIWRK, IFAIL
 DOUBLE PRECISION X(MX), Y(MY), F(MX*MY), S, LAMDA(NXEST),
1 MU(NYEST), C((NXEST-4)*(NYEST-4)), FP, WRK
2 (LWRK)
 CHARACTER*1 START

```

### 3. Description

This routine determines a smooth bicubic spline approximation  $s(x,y)$  to the set of data points  $(x_q, y_r, f_{q,r})$ , for  $q=1,2,\dots,m$  and  $r=1,2,\dots,m$ .

The spline is given in the B-spline representation

$$s(x,y) = \sum_{i=1}^{n-4} \sum_{j=1}^{n-4} c_{ij} M_i(x) N_j(y), \quad (1)$$

where  $M_i(x)$  and  $N_j(y)$  denote normalised cubic B-splines, the former defined on the knots  $(\lambda_i)$  to  $(\lambda_{i+4})$  and the latter on the knots  $(\mu_j)$  to  $(\mu_{j+4})$ . For further details, see Hayes and Halliday [4] for bicubic splines and de Boor [1] for normalised B-splines.

The total numbers  $n_x$  and  $n_y$  of these knots and their values  $(\lambda_1, \dots, \lambda_{n_x})$  and  $(\mu_1, \dots, \mu_{n_y})$  are chosen automatically by the routine. The knots  $(\lambda_5, \dots, \lambda_{n_x-4})$  and  $(\mu_5, \dots, \mu_{n_y-4})$  are the interior knots; they divide the approximation domain  $[x_x, x_{n_x}] \times [y_1, y_{n_y}]$  into (

$$\begin{matrix} & & 1 & m & & 1 & m \\ & & m & & & m & \\ n-7)*(n-7) & \text{subpanels} & [(\lambda) & ,(\lambda) & ]*[(\mu) & ,(\mu) & ], \\ x & y & i & i+1 & j & j+1 \\ \text{for } i=4,5,\dots,n-4, & j=4,5,\dots,n-4. & \text{Then, much as in the curve} \\ & x & y \\ \text{case (see E02BEF), the coefficients } c & \text{ are determined as the} \\ & ij \\ \text{solution of the following constrained minimization problem:} \end{matrix}$$

minimize

$$(\eta), \quad (2)$$

subject to the constraint

$$\begin{matrix} m & m \\ x & y \\ -- & -- \\ (\eta) = & & 2 \\ & & (\epsilon) < S, \\ -- & -- & q,r \\ q=1 & r=1 \end{matrix} \quad (3)$$

where  $(\eta)$  is a measure of the (lack of) smoothness of  $s(x,y)$ . Its value depends on the discontinuity jumps in  $s(x,y)$  across the boundaries of the subpanels. It is zero only when there are no discontinuities and is positive otherwise, increasing with the size of the jumps (see Dierckx [2] for details).

$(\epsilon)_{q,r}$  denotes the residual  $f_{q,r} - s(x,y)$ ,

and  $S$  is a non-negative number to be specified by the user.

By means of the parameter  $S$ , 'the smoothing factor', the user will then control the balance between smoothness and closeness of fit, as measured by the sum of squares of residuals in (3). If  $S$  is too large, the spline will be too smooth and signal will be lost (underfit); if  $S$  is too small, the spline will pick up too much noise (overfit). In the extreme cases the routine will return an interpolating spline  $((\eta)=0)$  if  $S$  is set to zero, and the least-squares bicubic polynomial  $((\eta)=0)$  if  $S$  is set very large. Experimenting with  $S$ -values between these two extremes should result in a good compromise. (See Section 8.3 for advice on choice of  $S$ .)

The method employed is outlined in Section 8.5 and fully described in Dierckx [2] and [3]. It involves an adaptive strategy for locating the knots of the bicubic spline (depending on the function underlying the data and on the value of S), and an iterative method for solving the constrained minimization problem once the knots have been determined.

Values of the computed spline can subsequently be computed by calling E02DEF or E02DFF as described in Section 8.6.

#### 5. Parameters

1: START -- CHARACTER\*1 Input  
 On entry: START must be set to 'C' or 'W'.

If START = 'C' (Cold start), the routine will build up the knot set starting with no interior knots. No values need be assigned to the parameters NX, NY, LAMDA, MU, WRK or IWRK.

If START = 'W' (Warm start), the routine will restart the knot-placing strategy using the knots found in a previous call of the routine. In this case, the parameters NX, NY, LAMDA, MU, WRK and IWRK must be unchanged from that previous call. This warm start can save much time in searching for a satisfactory value of S. Constraint: START = 'C' or 'W'.

- 2: MX -- INTEGER Input  
 On entry:  $m$  , the number of grid points along the  $x$  axis.  
 $x$   
 Constraint:  $MX \geq 4$ .
- 3: X(MX) -- DOUBLE PRECISION array Input  
 On entry:  $X(q)$  must be set to  $x$  , the  $x$  co-ordinate of the  
 $q$   
 $q$ th grid point along the  $x$  axis, for  $q=1,2,\dots,m$  .  
 $x$   
 Constraint:  $x_1 < x_2 < \dots < x_m$  .  
 $x$
- 4: MY -- INTEGER Input  
 On entry:  $m$  , the number of grid points along the  $y$  axis.  
 $y$   
 Constraint:  $MY \geq 4$ .
- 5: Y(MY) -- DOUBLE PRECISION array Input  
 On entry:  $Y(r)$  must be set to  $y$  , the  $y$  co-ordinate of the  
 $r$   
 $r$ th grid point along the  $y$  axis, for  $r=1,2,\dots,m$  .  
 $y$   
 Constraint:  $y_1 < y_2 < \dots < y_m$  .  
 $y$
- 6: F(MX\*MY) -- DOUBLE PRECISION array Input  
 On entry:  $F(m*(q-1)+r)$  must contain the data value  $f$  ,  
 $y$   $q,r$   
 for  $q=1,2,\dots,m$  and  $r=1,2,\dots,m$  .  
 $x$   $y$
- 7: S -- DOUBLE PRECISION Input  
 On entry: the smoothing factor,  $S$ .  
  
 If  $S=0.0$ , the routine returns an interpolating spline.  
  
 If  $S$  is smaller than machine precision, it is assumed equal to zero.  
  
 For advice on the choice of  $S$ , see Section 3 and Section 8.3  
 Constraint:  $S \geq 0.0$ .

- 8: NXEST -- INTEGER Input
- 9: NYEST -- INTEGER Input  
 On entry: an upper bound for the number of knots  $n_x$  and  $n_y$  required in the x- and y-directions respectively.
- In most practical situations,  $NXEST = m_x / 2$  and  $NYEST = m_y / 2$  is sufficient.  $NXEST$  and  $NYEST$  never need to be larger than  $m_x + 4$  and  $m_y + 4$  respectively, the numbers of knots needed for interpolation ( $S=0.0$ ). See also Section 8.4. Constraint:  $NXEST \geq 8$  and  $NYEST \geq 8$ .
- 10: NX -- INTEGER Input/Output  
 On entry: if the warm start option is used, the value of NX must be left unchanged from the previous call. On exit: the total number of knots,  $n_x$ , of the computed spline with respect to the x variable.
- 11: LAMDA(NXEST) -- DOUBLE PRECISION array Input/Output  
 On entry: if the warm start option is used, the values LAMDA(1), LAMDA(2), ..., LAMDA(NX) must be left unchanged from the previous call. On exit: LAMDA contains the complete set of knots ( $\lambda_i$ ) associated with the x variable, i.e., the interior knots LAMDA(5), LAMDA(6), ..., LAMDA(NX-4) as well as the additional knots LAMDA(1) = LAMDA(2) = LAMDA(3) = LAMDA(4) = X(1) and LAMDA(NX-3) = LAMDA(NX-2) = LAMDA(NX-1) = LAMDA(NX) = X(MX) needed for the B-spline representation.
- 12: NY -- INTEGER Input/Output  
 On entry: if the warm start option is used, the value of NY must be left unchanged from the previous call. On exit: the total number of knots,  $n_y$ , of the computed spline with respect to the y variable.
- 13: MU(NYEST) -- DOUBLE PRECISION array Input/Output  
 On entry: if the warm start option is used, the values MU(1), MU(2), ..., MU(NY) must be left unchanged from the previous call. On exit: MU contains the complete set of knots ( $\mu_i$ ) associated with the y variable, i.e., the

interior knots  $MU(5), MU(6), \dots, MU(NY-4)$  as well as the additional knots  $MU(1) = MU(2) = MU(3) = MU(4) = Y(1)$  and  $MU(NY-3) = MU(NY-2) = MU(NY-1) = MU(NY) = Y(MY)$  needed for the B-spline representation.

14:  $C((NXEST-4)*(NYEST-4))$  -- DOUBLE PRECISION array      Output  
On exit: the coefficients of the spline approximation.  $C((n-4)*(i-1)+j)$  is the coefficient  $c_{ij}$  defined in Section 3.

15:  $FP$  -- DOUBLE PRECISION      Output  
On exit: the sum of squared residuals,  $(theta)$ , of the computed spline approximation. If  $FP = 0.0$ , this is an interpolating spline.  $FP$  should equal  $S$  within a relative tolerance of 0.001 unless  $NX = NY = 8$ , when the spline has no interior knots and so is simply a bicubic polynomial. For knots to be inserted,  $S$  must be set to a value below the value of  $FP$  produced in this case.

16:  $WRK(LWRK)$  -- DOUBLE PRECISION array      Workspace  
On entry: if the warm start option is used, the values  $WRK(1), \dots, WRK(4)$  must be left unchanged from the previous call.

This array is used as workspace.

17:  $LWRK$  -- INTEGER      Input  
On entry:  
the dimension of the array  $WRK$  as declared in the (sub)program from which E02DCF is called.  
Constraint:  
 $LWRK \geq 4*(MX+MY) + 11*(NXEST+NYEST) + NXEST*MY + \max(MY, NXEST) + 54.$

18:  $IWRK(LIWRK)$  -- INTEGER array      Workspace  
On entry: if the warm start option is used, the values  $IWRK(1), \dots, IWRK(3)$  must be left unchanged from the previous call.

This array is used as workspace.

19:  $LIWRK$  -- INTEGER      Input  
On entry:  
the dimension of the array  $IWRK$  as declared in the (sub)program from which E02DCF is called.

Constraint:  $LIWRK \geq 3 + MX + MY + NXEST + NYEST$ .

20: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry START /= 'C' or 'W',

or  $MX < 4$ ,

or  $MY < 4$ ,

or  $S < 0.0$ ,

or  $S = 0.0$  and  $NXEST < MX + 4$ ,

or  $S = 0.0$  and  $NYEST < MY + 4$ ,

or  $NXEST < 8$ ,

or  $NYEST < 8$ ,

or  $LIWRK < 4*(MX+MY)+11*(NXEST+NYEST)+NXEST*MY+max(MY,NXEST)+54$

or  $LIWRK < 3 + MX + MY + NXEST + NYEST$ .

IFAIL= 2

The values of  $X(q)$ , for  $q = 1, 2, \dots, MX$ , are not in strictly increasing order.

IFAIL= 3

The values of  $Y(r)$ , for  $r = 1, 2, \dots, MY$ , are not in strictly increasing order.

IFAIL= 4

The number of knots required is greater than allowed by NXEST and NYEST. Try increasing NXEST and/or NYEST and, if necessary, supplying larger arrays for the parameters LAMDA, MU, C, WRK and IWRK. However, if NXEST and NYEST are already large, say  $NXEST > MX/2$  and  $NYEST > MY/2$ , then this error exit may indicate that S is too small.

IFAIL= 5

The iterative process used to compute the coefficients of the approximating spline has failed to converge. This error exit may occur if S has been set very small. If the error persists with increased S, consult NAG.

If IFAIL = 4 or 5, a spline approximation is returned, but it fails to satisfy the fitting criterion (see (2) and (3) in Section 3) -- perhaps by only a small amount, however.

## 7. Accuracy

On successful exit, the approximation returned is such that its sum of squared residuals FP is equal to the smoothing factor S, up to a specified relative tolerance of 0.001 - except that if  $n = 8$  and  $n = 8$ , FP may be significantly less than S: in this case

x            y

the computed spline is simply the least-squares bicubic polynomial approximation of degree 3, i.e., a spline with no interior knots.

## 8. Further Comments

### 8.1. Timing

The time taken for a call of E02DCF depends on the complexity of the shape of the data, the value of the smoothing factor S, and the number of data points. If E02DCF is to be called for different values of S, much time can be saved by setting START =

### 8.2. Weighting of Data Points

E02DCF does not allow individual weighting of the data values. If these were determined to widely differing accuracies, it may be better to use E02DDF. The computation time would be very much longer, however.

## 8.3. Choice of S

If the standard deviation of  $f$  is the same for all  $q$  and  $r$   
 $q, r$   
 (the case for which this routine is designed - see Section 8.2.)  
 and known to be equal, at least approximately, to  $(\sigma)$ , say,  
 then following Reinsch [5] and choosing the smoothing factor  $S$  in  
 $2$   
 the range  $(\sigma)(m \pm \sqrt{2}m)$ , where  $m = m_x m_y$ , is likely to give a  
 $x y$   
 good start in the search for a satisfactory value. If the  
 standard deviations vary, the sum of their squares over all the  
 data points could be used. Otherwise experimenting with different  
 values of  $S$  will be required from the start, taking account of  
 the remarks in Section 3.

In that case, in view of computation time and memory  
 requirements, it is recommended to start with a very large value  
 for  $S$  and so determine the least-squares bicubic polynomial; the  
 value returned for  $FP$ , call it  $FP_0$ , gives an upper bound for  $S$ .

Then progressively decrease the value of  $S$  to obtain closer fits  
 - say by a factor of 10 in the beginning, i.e.,  $S = FP_0 / 10$ ,

$S = FP_0 / 100$ , and so on, and more carefully as the approximation  
 $0$   
 shows more details.

The number of knots of the spline returned, and their location,  
 generally depend on the value of  $S$  and on the behaviour of the  
 function underlying the data. However, if E02DCF is called with  
 $START = 'W'$ , the knots returned may also depend on the smoothing  
 factors of the previous calls. Therefore if, after a number of  
 trials with different values of  $S$  and  $START = 'W'$ , a fit can  
 finally be accepted as satisfactory, it may be worthwhile to call  
 E02DCF once more with the selected value for  $S$  but now using  
 $START = 'C'$ . Often, E02DCF then returns an approximation with the  
 same quality of fit but with fewer knots, which is therefore  
 better if data reduction is also important.

## 8.4. Choice of NXEST and NYEST

The number of knots may also depend on the upper bounds  $NXEST$  and  
 $NYEST$ . Indeed, if at a certain stage in E02DCF the number of  
 knots in one direction (say  $n_x$ ) has reached the value of its

$x$

upper bound (NXEST), then from that moment on all subsequent knots are added in the other (y) direction. Therefore the user has the option of limiting the number of knots the routine locates in any direction. For example, by setting NXEST = 8 (the lowest allowable value for NXEST), the user can indicate that he wants an approximation which is a simple cubic polynomial in the variable x.

#### 8.5. Outline of Method Used

If  $S=0$ , the requisite number of knots is known in advance, i.e.,  $n = m + 4$  and  $n = m + 4$ ; the interior knots are located immediately

as  $(\lambda)_i = x_{i-2}$  and  $(\mu)_j = y_{j-2}$ , for  $i=5,6,\dots,n-4$  and  $j=5,6,\dots,n-4$ . The corresponding least-squares spline is then an interpolating spline and therefore a solution of the problem.

If  $S>0$ , suitable knot sets are built up in stages (starting with no interior knots in the case of a cold start but with the knot set found in a previous call if a warm start is chosen). At each stage, a bicubic spline is fitted to the data by least-squares, and  $(\theta)$ , the sum of squares of residuals, is computed. If  $(\theta)>S$ , new knots are added to one knot set or the other so as to reduce  $(\theta)$  at the next stage. The new knots are located in intervals where the fit is particularly poor, their number depending on the value of  $S$  and on the progress made so far in reducing  $(\theta)$ . Sooner or later, we find that  $(\theta)\leq S$  and at that point the knot sets are accepted. The routine then goes on to compute the (unique) spline which has these knot sets and which satisfies the full fitting criterion specified by (2) and (3). The theoretical solution has  $(\theta)=S$ . The routine computes the spline by an iterative scheme which is ended when  $(\theta)=S$  within a relative tolerance of 0.001. The main part of each iteration consists of a linear least-squares computation of special form, done in a similarly stable and efficient manner as in E02BAF for least-squares curve fitting.

An exception occurs when the routine finds at the start that, even with no interior knots ( $n = n = 8$ ), the least-squares spline

already has its sum of residuals  $\leq S$ . In this case, since this spline (which is simply a bicubic polynomial) also has an optimal value for the smoothness measure  $(\eta)$ , namely zero, it is returned at once as the (trivial) solution. It will usually mean

that  $S$  has been chosen too large.

For further details of the algorithm and its use see Dierckx [2].

### 8.6. Evaluation of Computed Spline

The values of the computed spline at the points  $(TX(r), TY(r))$ , for  $r = 1, 2, \dots, N$ , may be obtained in the double precision array  $FF$ , of length at least  $N$ , by the following code:

```
IFAIL = 0
CALL E02DEF(N,NX,NY,TX,TY,LAMDA,MU,C,FF,WRK,IWRK,IFAIL)
```

where  $NX$ ,  $NY$ ,  $LAMDA$ ,  $MU$  and  $C$  are the output parameters of  $E02DCF$ ,  $WRK$  is a double precision workspace array of length at least  $NY-4$ , and  $IWRK$  is an integer workspace array of length at least  $NY-4$ .

To evaluate the computed spline on a  $KX$  by  $KY$  rectangular grid of points in the  $x$ - $y$  plane, which is defined by the  $x$  co-ordinates stored in  $TX(q)$ , for  $q=1, 2, \dots, KX$ , and the  $y$  co-ordinates stored in  $TY(r)$ , for  $r=1, 2, \dots, KY$ , returning the results in the double precision array  $FG$  which is of length at least  $KX*KY$ , the following call may be used:

```
IFAIL = 0
CALL E02DFF(KX,KY,NX,NY,TX,TY,LAMDA,MU,C,FG,WRK,LWRK,
* IWRK,LIWRK,IFAIL)
```

where  $NX$ ,  $NY$ ,  $LAMDA$ ,  $MU$  and  $C$  are the output parameters of  $E02DCF$ ,  $WRK$  is a double precision workspace array of length at least  $LWRK = \min(NWRK1, NWRK2)$ ,  $NWRK1 = KX*4+NX$ ,  $NWRK2 = KY*4+NY$ , and  $IWRK$  is an integer workspace array of length at least  $LIWRK = KY + NY - 4$  if  $NWRK1 \geq NWRK2$ , or  $KX + NX - 4$  otherwise. The result of the spline evaluated at grid point  $(q,r)$  is returned in element  $(KY*(q-1)+r)$  of the array  $FG$ .

### 9. Example

This example program reads in values of  $MX$ ,  $MY$ ,  $x$ , for  $q = 1, 2, \dots, q$

ordinates  $f$  defined at the grid points  $(x, y)$ . It then calls  $E02DCF$  to compute a bicubic spline approximation for one specified value of  $S$ , and prints the values of the computed knots

and B-spline coefficients. Finally it evaluates the spline at a small sample of points on a rectangular grid.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E02 -- Curve and Surface Fitting

E02DDF

E02DDF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

E02DDF computes a bicubic spline approximation to a set of scattered data. The knots of the spline are located automatically, but a single parameter must be specified to control the trade-off between closeness of fit and smoothness of fit.

### 2. Specification

```

SUBROUTINE E02DDF (START, M, X, Y, F, W, S, NXEST, NYEST,
1 NX, LAMDA, NY, MU, C, FP, RANK, WRK,
2 LWRK, IWRK, LIWRK, IFAIL)
 INTEGER M, NXEST, NYEST, NX, NY, RANK, LWRK, IWRK
1 (LIWRK), LIWRK, IFAIL
 DOUBLE PRECISION X(M), Y(M), F(M), W(M), S, LAMDA(NXEST),
1 MU(NYEST), C((NXEST-4)*(NYEST-4)), FP, WRK
2 (LWRK)
 CHARACTER*1 START

```

### 3. Description

This routine determines a smooth bicubic spline approximation  $s(x,y)$  to the set of data points  $(x_r, y_r, f_r)$  with weights  $w_r$ , for  $r=1,2,\dots,m$ .

The approximation domain is considered to be the rectangle  $[x_{\min}, x_{\max}] \times [y_{\min}, y_{\max}]$ , where  $x_{\min}$  ( $y_{\min}$ ) and  $x_{\max}$  ( $y_{\max}$ ) denote

min max min max min min max max  
the lowest and highest data values of  $x$  ( $y$ ).

The spline is given in the B-spline representation

$$s(x,y) = \sum_{i=1}^{n-4} \sum_{j=1}^{n-4} c_{ij} M_i(x) N_j(y), \quad (1)$$

where  $M_i(x)$  and  $N_j(y)$  denote normalised cubic B-splines, the former defined on the knots  $(\lambda_1)$  to  $(\lambda_{i+4})$  and the latter on the knots  $(\mu_1)$  to  $(\mu_{j+4})$ . For further details, see Hayes and Halliday [4] for bicubic splines and de Boor [1] for normalised B-splines.

The total numbers  $n_x$  and  $n_y$  of these knots and their values

$(\lambda_1), \dots, (\lambda_{n_x})$  and  $(\mu_1), \dots, (\mu_{n_y})$  are chosen

automatically by the routine. The knots  $(\lambda_5), \dots, (\lambda_{n_x-4})$  and  $(\mu_5), \dots, (\mu_{n_y-4})$  are the interior knots; they

divide the approximation domain  $[x_{\min}, x_{\max}] \times [y_{\min}, y_{\max}]$  into  $(n_x - 7) \times (n_y - 7)$  subpanels  $[(\lambda_i), (\lambda_{i+1})] \times [(\mu_j), (\mu_{j+1})]$ , for  $i=4, 5, \dots, n_x-4$ ;  $j=4, 5, \dots, n_y-4$ . Then, much as in the curve

case (see E02BEF), the coefficients  $c_{ij}$  are determined as the solution of the following constrained minimization problem:

minimize

$$(\eta), \quad (2)$$

subject to the constraint

$$\begin{array}{rcl}
 & m & \\
 & -- & 2 \\
 (\text{theta}) = & > & (\text{epsilon}) \leq S \\
 & -- & r \\
 & r=1 & 
 \end{array} \tag{3}$$

where:  $(\text{eta})$  is a measure of the (lack of) smoothness of  $s(x,y)$ . Its value depends on the discontinuity jumps in  $s(x,y)$  across the boundaries of the subpanels. It is zero only when there are no discontinuities and is positive otherwise, increasing with the size of the jumps (see Dierckx [2] for details).

$(\text{epsilon})_r$  denotes the weighted residual  $w_r(f - s(x,y))$ ,

and  $S$  is a non-negative number to be specified by the user.

By means of the parameter  $S$ , 'the smoothing factor', the user will then control the balance between smoothness and closeness of fit, as measured by the sum of squares of residuals in (3). If  $S$  is too large, the spline will be too smooth and signal will be lost (underfit); if  $S$  is too small, the spline will pick up too much noise (overfit). In the extreme cases the method would return an interpolating spline ( $(\text{theta})=0$ ) if  $S$  were set to zero, and returns the least-squares bicubic polynomial ( $(\text{eta})=0$ ) if  $S$  is set very large. Experimenting with  $S$ -values between these two extremes should result in a good compromise. (See Section 8.2 for advice on choice of  $S$ .) Note however, that this routine, unlike E02BEF and E02DCF, does not allow  $S$  to be set exactly to zero: to compute an interpolant to scattered data, E01SAF or E01SEF should be used.

The method employed is outlined in Section 8.5 and fully described in Dierckx [2] and [3]. It involves an adaptive strategy for locating the knots of the bicubic spline (depending on the function underlying the data and on the value of  $S$ ), and an iterative method for solving the constrained minimization problem once the knots have been determined.

Values of the computed spline can subsequently be computed by calling E02DEF or E02DFF as described in Section 8.6.

#### 5. Parameters

- 1: START -- CHARACTER\*1 Input  
 On entry: START must be set to 'C' or 'W'.

If START = 'C' (Cold start), the routine will build up the knot set starting with no interior knots. No values need be assigned to the parameters NX, NY, LAMDA, MU or WRK.

If START = 'W' (Warm start), the routine will restart the knot-placing strategy using the knots found in a previous call of the routine. In this case, the parameters NX, NY, LAMDA, MU and WRK must be unchanged from that previous call. This warm start can save much time in searching for a satisfactory value of S. Constraint: START = 'C' or 'W'.

- 2: M -- INTEGER Input  
 On entry: m, the number of data points.

The number of data points with non-zero weight (see W below) must be at least 16.

- 3: X(M) -- DOUBLE PRECISION array Input
- 4: Y(M) -- DOUBLE PRECISION array Input

- 5: F(M) -- DOUBLE PRECISION array Input  
 On entry:  $X(r)$ ,  $Y(r)$ ,  $F(r)$  must be set to the co-ordinates of  $(x_r, y_r, f_r)$ , the  $r$ th data point, for  $r=1,2,\dots,m$ . The order of the data points is immaterial.
- 6: W(M) -- DOUBLE PRECISION array Input  
 On entry:  $W(r)$  must be set to  $w_r$ , the  $r$ th value in the set of weights, for  $r=1,2,\dots,m$ . Zero weights are permitted and the corresponding points are ignored, except when determining  $x_{\min}$ ,  $x_{\max}$ ,  $y_{\min}$  and  $y_{\max}$  (see Section 8.4). For advice on the choice of weights, see Section 2.1.2 of the Chapter Introduction. Constraint: the number of data points with non-zero weight must be at least 16.
- 7: S -- DOUBLE PRECISION Input  
 On entry: the smoothing factor, S.  
  
 For advice on the choice of S, see Section 3 and Section 8.2. Constraint:  $S > 0.0$ .
- 8: NXEST -- INTEGER Input
- 9: NYEST -- INTEGER Input  
 On entry: an upper bound for the number of knots  $n_x$  and  $n_y$  required in the x- and y-directions respectively.  
  
 In most practical situations,  $NXEST = NYEST = 4 + \sqrt{m}/2$  is sufficient. See also Section 8.3. Constraint:  $NXEST \geq 8$  and  $NYEST \geq 8$ .
- 10: NX -- INTEGER Input/Output  
 On entry: if the warm start option is used, the value of NX must be left unchanged from the previous call. On exit: the total number of knots,  $n_x$ , of the computed spline with respect to the x variable.
- 11: LAMDA(NXEST) -- DOUBLE PRECISION array Input/Output  
 On entry: if the warm start option is used, the values LAMDA(1), LAMDA(2), ..., LAMDA(NX) must be left unchanged from the previous call. On exit: LAMDA contains the complete set of

- knots (lambda) associated with the x variable, i.e., the interior knots  $\text{LAMDA}(5), \text{LAMDA}(6), \dots, \text{LAMDA}(\text{NX}-4)$  as well as the additional knots  $\text{LAMDA}(1) = \text{LAMDA}(2) = \text{LAMDA}(3) = \text{LAMDA}(4) = x_{\min}$  and  $\text{LAMDA}(\text{NX}-3) = \text{LAMDA}(\text{NX}-2) = \text{LAMDA}(\text{NX}-1) = x_{\max}$  needed for the B-spline representation (where  $x_{\min}$  and  $x_{\max}$  are as described in Section 3).
- 12: NY -- INTEGER Input/Output  
 On entry: if the warm start option is used, the value of NY must be left unchanged from the previous call. On exit: the total number of knots, n, of the computed spline with respect to the y variable.
- 13: MU(NYEST) -- DOUBLE PRECISION array Input/Output  
 On entry: if the warm start option is used, the values MU(1), MU(2), ..., MU(NY) must be left unchanged from the previous call. On exit: MU contains the complete set of knots (mu) associated with the y variable, i.e., the interior knots MU(5), MU(6), ..., MU(NY-4) as well as the additional knots MU(1) = MU(2) = MU(3) = MU(4) = y<sub>min</sub> and MU(NY-3) = MU(NY-2) = MU(NY-1) = MU(NY) = y<sub>max</sub> needed for the B-spline representation (where y<sub>min</sub> and y<sub>max</sub> are as described in Section 3).
- 14: C((NXEST-4)\*(NYEST-4)) -- DOUBLE PRECISION array Output  
 On exit: the coefficients of the spline approximation. C((n-4)\*(i-1)+j) is the coefficient c<sub>ij</sub> defined in Section 3.
- 15: FP -- DOUBLE PRECISION Output  
 On exit: the weighted sum of squared residuals, (theta), of the computed spline approximation. FP should equal S within a relative tolerance of 0.001 unless NX = NY = 8, when the spline has no interior knots and so is simply a bicubic polynomial. For knots to be inserted, S must be set to a value below the value of FP produced in this case.

16: RANK -- INTEGER Output  
 On exit: RANK gives the rank of the system of equations used to compute the final spline (as determined by a suitable machine-dependent threshold). When  $RANK = (NX-4)*(NY-4)$ , the solution is unique; otherwise the system is rank-deficient and the minimum-norm solution is computed. The latter case may be caused by too small a value of  $S$ .

17: WRK(LWRK) -- DOUBLE PRECISION array Workspace  
 On entry: if the warm start option is used, the value of WRK(1) must be left unchanged from the previous call.

This array is used as workspace.

18: LWRK -- INTEGER Input  
 On entry:  
 the dimension of the array WRK as declared in the (sub)program from which E02DDF is called.  
 Constraint:  $LWRK \geq (7*u*v+25*w)*(w+1)+2*(u+v+4*M)+23*w+56$ ,

where

$u = NXEST-4$ ,  $v = NYEST-4$ , and  $w = \max(u, v)$ .

For some problems, the routine may need to compute the minimal least-squares solution of a rank-deficient system of linear equations (see Section 3). The amount of workspace required to solve such problems will be larger than specified by the value given above, which must be increased by an amount, LWRK2 say. An upper bound for LWRK2 is given by  $4*u*v*w+2*u*v+4*w$ , where  $u$ ,  $v$  and  $w$  are as above. However, if there are enough data points, scattered uniformly over the approximation domain, and if the smoothing factor  $S$  is not too small, there is a good chance that this extra workspace is not needed. A lot of memory might therefore be saved by assuming  $LWRK2 = 0$ .

19: IWRK(LIWRK) -- INTEGER array Workspace

20: LIWRK -- INTEGER Input  
 On entry:  
 the dimension of the array IWRK as declared in the (sub)program from which E02DDF is called.  
 Constraint:  $LIWRK \geq M+2*(NXEST-7)*(NYEST-7)$ .

21: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry START /= 'C' or 'W',

or the number of data points with non-zero weight < 16,

or  $S \leq 0.0$ ,

or NXEST < 8,

or NYEST < 8,

or  $LWRK < (7*u*v+25*w)*(w+1)+2*(u+v+4*M)+23*w+56$ ,  
 where  $u = NXEST - 4$ ,  $v = NYEST - 4$  and  $w = \max(u, v)$ ,

or  $LIWRK < M+2*(NXEST-7)*(NYEST-7)$ .

IFAIL= 2

On entry either all the  $X(r)$ , for  $r = 1, 2, \dots, M$ , are equal,  
 or all the  $Y(r)$ , for  $r = 1, 2, \dots, M$ , are equal.

IFAIL= 3

The number of knots required is greater than allowed by NXEST and NYEST. Try increasing NXEST and/or NYEST and, if necessary, supplying larger arrays for the parameters LAMDA, MU, C, WRK and IWRK. However, if NXEST and NYEST are already

large, say  $NXEST, NYEST > 4 + \sqrt{M/2}$ , then this error exit may indicate that  $S$  is too small.

## IFAIL= 4

No more knots can be added because the number of B-spline coefficients  $(NX-4)*(NY-4)$  already exceeds the number of data points  $M$ . This error exit may occur if either of  $S$  or  $M$  is too small.

## IFAIL= 5

No more knots can be added because the additional knot would (quasi) coincide with an old one. This error exit may occur if too large a weight has been given to an inaccurate data point, or if  $S$  is too small.

## IFAIL= 6

The iterative process used to compute the coefficients of the approximating spline has failed to converge. This error exit may occur if  $S$  has been set very small. If the error persists with increased  $S$ , consult NAG.

## IFAIL= 7

LWRK is too small; the routine needs to compute the minimal least-squares solution of a rank-deficient system of linear equations, but there is not enough workspace. There is no approximation returned but, having saved the information contained in  $NX$ ,  $LAMDA$ ,  $NY$ ,  $MU$  and  $WRK$ , and having adjusted the value of  $LWRK$  and the dimension of array  $WRK$  accordingly, the user can continue at the point the program was left by calling E02DDF with  $START = 'W'$ . Note that the requested value for  $LWRK$  is only large enough for the current phase of the algorithm. If the routine is restarted with  $LWRK$  set to the minimum value requested, a larger request may be made at a later stage of the computation. See Section 5 for the upper bound on  $LWRK$ . On soft failure, the minimum requested value for  $LWRK$  is returned in  $IWRK(1)$  and the safe value for  $LWRK$  is returned in  $IWRK(2)$ .

If  $IFAIL = 3, 4, 5$  or  $6$ , a spline approximation is returned, but it fails to satisfy the fitting criterion (see (2) and (3) in Section 3 -- perhaps only by a small amount, however.

## 7. Accuracy

On successful exit, the approximation returned is such that its weighted sum of squared residuals  $FP$  is equal to the smoothing factor  $S$ , up to a specified relative tolerance of 0.001 - except that if  $n_x = 8$  and  $n_y = 8$ ,  $FP$  may be significantly less than  $S$ : in

$x \qquad y$

this case the computed spline is simply the least-squares bicubic polynomial approximation of degree 3, i.e., a spline with no interior knots.

## 8. Further Comments

### 8.1. Timing

The time taken for a call of E02DDF depends on the complexity of the shape of the data, the value of the smoothing factor  $S$ , and the number of data points. If E02DDF is to be called for different values of  $S$ , much time can be saved by setting  $START =$  It should be noted that choosing  $S$  very small considerably increases computation time.

### 8.2. Choice of $S$

If the weights have been correctly chosen (see Section 2.1.2 of the Chapter Introduction), the standard deviation of  $w_r$  would

be the same for all  $r$ , equal to  $(\sigma_r)^2$ , say. In this case,

choosing the smoothing factor  $S$  in the range  $(\sigma_r)^2 (m \pm \sqrt{2m})$ , as suggested by Reinsch [6], is likely to give a good start in the search for a satisfactory value. Otherwise, experimenting with different values of  $S$  will be required from the start.

In that case, in view of computation time and memory requirements, it is recommended to start with a very large value for  $S$  and so determine the least-squares bicubic polynomial; the value returned for  $FP$ , call it  $FP_0$ , gives an upper bound for  $S$ .

Then progressively decrease the value of  $S$  to obtain closer fits - say by a factor of 10 in the beginning, i.e.,  $S = FP_0 / 10$ ,

$S = FP_0 / 100$ , and so on, and more carefully as the approximation

shows more details.

To choose  $S$  very small is strongly discouraged. This considerably increases computation time and memory requirements. It may also cause rank-deficiency (as indicated by the parameter  $RANK$ ) and endanger numerical stability.

The number of knots of the spline returned, and their location, generally depend on the value of  $S$  and on the behaviour of the

function underlying the data. However, if E02DDF is called with  $\text{START} = 'W'$ , the knots returned may also depend on the smoothing factors of the previous calls. Therefore if, after a number of trials with different values of  $S$  and  $\text{START} = 'W'$ , a fit can finally be accepted as satisfactory, it may be worthwhile to call E02DDF once more with the selected value for  $S$  but now using  $\text{START} = 'C'$ . Often, E02DDF then returns an approximation with the same quality of fit but with fewer knots, which is therefore better if data reduction is also important.

### 8.3. Choice of NXEST and NYEST

The number of knots may also depend on the upper bounds NXEST and NYEST. Indeed, if at a certain stage in E02DDF the number of knots in one direction (say  $n$ ) has reached the value of its

$x$

upper bound (NXEST), then from that moment on all subsequent knots are added in the other ( $y$ ) direction. This may indicate that the value of NXEST is too small. On the other hand, it gives the user the option of limiting the number of knots the routine locates in any direction. For example, by setting  $\text{NXEST} = 8$  (the lowest allowable value for NXEST), the user can indicate that he wants an approximation which is a simple cubic polynomial in the variable  $x$ .

### 8.4. Restriction of the approximation domain

The fit obtained is not defined outside the rectangle  $[(\lambda_4), (\lambda_{n-3})] \times [(\mu_4), (\mu_{n-3})]$ . The reason for taking

$x \qquad y$

the extreme data values of  $x$  and  $y$  for these four knots is that, as is usual in data fitting, the fit cannot be expected to give satisfactory values outside the data region. If, nevertheless, the user requires values over a larger rectangle, this can be achieved by augmenting the data with two artificial data points  $(a, c, 0)$  and  $(b, d, 0)$  with zero weight, where  $[a, b] \times [c, d]$  denotes the enlarged rectangle.

### 8.5. Outline of method used

First suitable knot sets are built up in stages (starting with no interior knots in the case of a cold start but with the knot set found in a previous call if a warm start is chosen). At each stage, a bicubic spline is fitted to the data by least-squares and  $(\theta)$ , the sum of squares of residuals, is computed. If

(theta)>S, a new knot is added to one knot set or the other so as to reduce (theta) at the next stage. The new knot is located in an interval where the fit is particularly poor. Sooner or later, we find that (theta)<=S and at that point the knot sets are accepted. The routine then goes on to compute a spline which has these knot sets and which satisfies the full fitting criterion specified by (2) and (3). The theoretical solution has (theta)=S. The routine computes the spline by an iterative scheme which is ended when (theta)=S within a relative tolerance of 0.001. The main part of each iteration consists of a linear least-squares computation of special form, done in a similarly stable and efficient manner as in E02DAF. As there also, the minimal least-squares solution is computed wherever the linear system is found to be rank-deficient.

An exception occurs when the routine finds at the start that, even with no interior knots ( $N = 8$ ), the least-squares spline already has its sum of squares of residuals  $\leq S$ . In this case, since this spline (which is simply a bicubic polynomial) also has an optimal value for the smoothness measure (eta), namely zero, it is returned at once as the (trivial) solution. It will usually mean that S has been chosen too large.

For further details of the algorithm and its use see Dierckx [2].

#### 8.6. Evaluation of computed spline

The values of the computed spline at the points (TX(r),TY(r)), for  $r = 1, 2, \dots, N$ , may be obtained in the double precision array FF, of length at least N, by the following code:

```
IFAIL = 0
CALL E02DEF(N,NX,NY,TX,TY,LAMDA,MU,C,FF,WRK,IWRK,IFAIL)
```

where NX, NY, LAMDA, MU and C are the output parameters of E02DDF, WRK is a double precision workspace array of length at least NY-4, and IWRK is an integer workspace array of length at least NY-4.

To evaluate the computed spline on a KX by KY rectangular grid of points in the x-y plane, which is defined by the x co-ordinates stored in TX(q), for  $q=1, 2, \dots, KX$ , and the y co-ordinates stored in TY(r), for  $r=1, 2, \dots, KY$ , returning the results in the double precision array FG which is of length at least KX\*KY, the

following call may be used:

```

 IFAIL = 0
 CALL E02DFF(KX,KY,NX,NY,TX,TY,LAMDA,MU,C,FG,WRK,LWRK,
* IWRK,LIWRK,IFAIL)

```

where NX, NY, LAMDA, MU and C are the output parameters of E02DDF, WRK is a double precision workspace array of length at least  $LWRK = \min(NWRK1, NWRK2)$ ,  $NWRK1 = KX*4 + NX$ ,  $NWRK2 = KY*4 + NY$ , and IWRK is an integer workspace array of length at least  $LIWRK = KY + NY - 4$  if  $NWRK1 \geq NWRK2$ , or  $KX + NX - 4$  otherwise. The result of the spline evaluated at grid point (q,r) is returned in element  $(KY*(q-1)+r)$  of the array FG.

### 9. Example

This example program reads in a value of M, followed by a set of M data points  $(x_r, y_r, f_r)$  and their weights  $w_r$ . It then calls

E02DDF to compute a bicubic spline approximation for one specified value of S, and prints the values of the computed knots and B-spline coefficients. Finally it evaluates the spline at a small sample of points on a rectangular grid.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E02 -- Curve and Surface Fitting

E02DEF

E02DEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

E02DEF calculates values of a bicubic spline from its B-spline representation.

### 2. Specification

```

SUBROUTINE E02DEF (M, PX, PY, X, Y, LAMDA, MU, C, FF, WRK,
1 IWRK, IFAIL)
INTEGER M, PX, PY, IWRK(PY-4), IFAIL
DOUBLE PRECISION X(M), Y(M), LAMDA(PX), MU(PY), C((PX-4)*
1 (PY-4)), FF(M), WRK(PY-4)

```

### 3. Description

This routine calculates values of the bicubic spline  $s(x,y)$  at prescribed points  $(x_r, y_r)$ , for  $r=1,2,\dots,m$ , from its augmented knot sets  $\{(\lambda)\}$  and  $\{(\mu)\}$  and from the coefficients  $c_{ij}$ , for  $i=1,2,\dots,PX-4$ ;  $j=1,2,\dots,PY-4$ , in its B-spline representation

$$s(x,y) = \sum_{ij} c_{ij} M_i(x) N_j(y).$$

Here  $M_i(x)$  and  $N_j(y)$  denote normalised cubic B-splines, the former defined on the knots  $(\lambda)_i$  to  $(\lambda)_{i+4}$  and the latter on the knots  $(\mu)_j$  to  $(\mu)_{j+4}$ .

This routine may be used to calculate values of a bicubic spline given in the form produced by E01DAF, E02DAF, E02DCF and E02DDF. It is derived from the routine B2VRE in Anthony et al [1].

### 5. Parameters

1: M -- INTEGER Input  
On entry: m, the number of points at which values of the

spline are required. Constraint:  $M \geq 1$ .

- 2: PX -- INTEGER Input
- 3: PY -- INTEGER Input  
 On entry: PX and PY must specify the total number of knots associated with the variables  $x$  and  $y$  respectively. They are such that PX-8 and PY-8 are the corresponding numbers of interior knots. Constraint:  $PX \geq 8$  and  $PY \geq 8$ .
- 4: X(M) -- DOUBLE PRECISION array Input
- 5: Y(M) -- DOUBLE PRECISION array Input  
 On entry: X and Y must contain  $x_r$  and  $y_r$ , for  $r=1,2,\dots,m$ , respectively. These are the co-ordinates of the points at which values of the spline are required. The order of the points is immaterial. Constraint: X and Y must satisfy
- $$LAMDA(4) \leq X(r) \leq LAMDA(PX-3)$$
- and
- $$MU(4) \leq Y(r) \leq MU(PY-3), \text{ for } r=1,2,\dots,m.$$
- The spline representation is not valid outside these intervals.
- 6: LAMDA(PX) -- DOUBLE PRECISION array Input
- 7: MU(PY) -- DOUBLE PRECISION array Input  
 On entry: LAMDA and MU must contain the complete sets of knots  $\{(\lambda)\}$  and  $\{(\mu)\}$  associated with the  $x$  and  $y$  variables respectively. Constraint: the knots in each set must be in non-decreasing order, with  $LAMDA(PX-3) > LAMDA(4)$  and  $MU(PY-3) > MU(4)$ .
- 8: C((PX-4)\*(PY-4)) -- DOUBLE PRECISION array Input  
 On entry: C((PY-4)\*(i-1)+j) must contain the coefficient  $c_{ij}$  described in Section 3, for  $i=1,2,\dots,PX-4$ ;  $j=1,2,\dots,PY-4$ .
- 9: FF(M) -- DOUBLE PRECISION array Output  
 On exit: FF(r) contains the value of the spline at the point  $(x, y)$ , for  $r=1,2,\dots,m$ .

r   r

- 10: WRK(PY-4) -- DOUBLE PRECISION array                      Workspace
- 11: IWRK(PY-4) -- INTEGER array                                  Workspace
- 12: IFAIL -- INTEGER                                              Input/Output
- On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry  $M < 1$ ,

or             $PY < 8$ ,

or             $PX < 8$ .

IFAIL= 2

On entry the knots in array LAMDA, or those in array MU, are not in non-decreasing order, or  $LAMDA(PX-3) \leq LAMDA(4)$ , or  $MU(PY-3) \leq MU(4)$ .

IFAIL= 3

On entry at least one of the prescribed points  $(x_r, y_r)$  lies outside the rectangle defined by  $LAMDA(4)$ ,  $LAMDA(PX-3)$  and  $MU(4)$ ,  $MU(PY-3)$ .

#### 7. Accuracy

The method used to evaluate the B-splines is numerically stable, in the sense that each computed value of  $s(x_r, y_r)$  can be regarded

r   r

as the value that would have been obtained in exact arithmetic from slightly perturbed B-spline coefficients. See Cox [2] for

details.

### 8. Further Comments

Computation time is approximately proportional to the number of points,  $m$ , at which the evaluation is required.

### 9. Example

This program reads in knot sets  $LAMDA(1), \dots, LAMDA(PX)$  and  $MU(1), \dots, MU(PY)$ , and a set of bicubic spline coefficients  $c_{ij}$ .

Following these are a value for  $m$  and the co-ordinates  $(x_r, y_r)$ , for  $r=1, 2, \dots, m$ , at which the spline is to be evaluated.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E02 -- Curve and Surface Fitting

E02DFF

E02DFF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

E02DFF calculates values of a bicubic spline from its B-spline representation. The spline is evaluated at all points on a rectangular grid.

### 2. Specification

```

SUBROUTINE E02DFF (MX, MY, PX, PY, X, Y, LAMDA, MU, C, FF,
1 WRK, LWRK, IWRK, LIWRK, IFAIL)
 INTEGER MX, MY, PX, PY, LWRK, IWRK(LIWRK), LIWRK,
1 IFAIL
 DOUBLE PRECISION X(MX), Y(MY), LAMDA(PX), MU(PY), C((PX-4)*
1 (PY-4)), FF(MX*MY), WRK(LWRK)

```

### 3. Description

This routine calculates values of the bicubic spline  $s(x,y)$  on a rectangular grid of points in the  $x$ - $y$  plane, from its augmented knot sets  $\{(\lambda)\}$  and  $\{(\mu)\}$  and from the coefficients  $c_{ij}$ , for  $i=1,2,\dots,PX-4$ ;  $j=1,2,\dots,PY-4$ , in its B-spline representation

$$s(x,y) = \sum_{ij} c_{ij} M_i(x) N_j(y).$$

Here  $M_i(x)$  and  $N_j(y)$  denote normalised cubic B-splines, the former defined on the knots  $(\lambda)_i$  to  $(\lambda)_{i+4}$  and the latter on the knots  $(\mu)_j$  to  $(\mu)_{j+4}$ .

The points in the grid are defined by co-ordinates  $x_q$ , for  $q=1,2,\dots,m$ , along the  $x$  axis, and co-ordinates  $y_r$ , for  $r=1,2,\dots,m$  along the  $y$  axis.

This routine may be used to calculate values of a bicubic spline given in the form produced by E01DAF, E02DAF, E02DCF and E02DDF. It is derived from the routine B2VRE in Anthony et al [1].

#### 5. Parameters

- 1: MX -- INTEGER Input
  - 2: MY -- INTEGER Input
- On entry: MX and MY must specify  $m$  and  $m$  respectively,

x            y

the number of points along the x and y axis that define the rectangular grid. Constraint:  $MX \geq 1$  and  $MY \geq 1$ .

- 3: PX -- INTEGER Input
- 4: PY -- INTEGER Input  
 On entry: PX and PY must specify the total number of knots associated with the variables x and y respectively. They are such that PX-8 and PY-8 are the corresponding numbers of interior knots. Constraint:  $PX \geq 8$  and  $PY \geq 8$ .
- 5: X(MX) -- DOUBLE PRECISION array Input
- 6: Y(MY) -- DOUBLE PRECISION array Input  
 On entry: X and Y must contain  $x_q$ , for  $q=1,2,\dots,m$ , and  $y_r$ , for  $r=1,2,\dots,m$ , respectively. These are the x and y coordinates that define the rectangular grid of points at which values of the spline are required. Constraint: X and Y must satisfy
- $$LAMDA(4) \leq X(q) < X(q+1) \leq LAMDA(PX-3), \text{ for } q=1,2,\dots,m-1$$
- x
- and
- $$MU(4) \leq Y(r) < Y(r+1) \leq MU(PY-3), \text{ for } r=1,2,\dots,m-1.$$
- y
- The spline representation is not valid outside these intervals.
- 7: LAMDA(PX) -- DOUBLE PRECISION array Input
- 8: MU(PY) -- DOUBLE PRECISION array Input  
 On entry: LAMDA and MU must contain the complete sets of knots  $\{(\lambda)\}$  and  $\{(\mu)\}$  associated with the x and y variables respectively. Constraint: the knots in each set must be in non-decreasing order, with  $LAMDA(PX-3) > LAMDA(4)$  and  $MU(PY-3) > MU(4)$ .
- 9: C((PX-4)\*(PY-4)) -- DOUBLE PRECISION array Input  
 On entry: C((PY-4)\*(i-1)+j) must contain the coefficient  $c_{ij}$  described in Section 3, for  $i=1,2,\dots,PX-4$ ;  
 ij

```

10: FF(MX*MY) -- DOUBLE PRECISION array Output
 On exit: FF(MY*(q-1)+r) contains the value of the spline at
 the point (x ,y), for q=1,2,...,m ; r=1,2,...,m .
 q r x y

11: WRK(LWRK) -- DOUBLE PRECISION array Workspace

12: LWRK -- INTEGER Input
 On entry:
 the dimension of the array WRK as declared in the
 (sub)program from which E02DFF is called.
 Constraint: LWRK >= min(NWRK1,NWRK2), where NWRK1=4*MX+PX,
 NWRK2=4*MY+PY.

13: IWRK(LIWRK) -- INTEGER array Workspace

14: LIWRK -- INTEGER Input
 On entry:
 the dimension of the array IWRK as declared in the
 (sub)program from which E02DFF is called.
 Constraint: LIWRK >= MY + PY - 4 if NWRK1 > NWRK2, or MX +
 PX - 4 otherwise, where NWRK1 and NWRK2 are as defined in
 the description of argument LWRK.

15: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not
 familiar with this parameter (described in the Essential
 Introduction) the recommended value is 0.

 On exit: IFAIL = 0 unless the routine detects an error (see
 Section 6).

```

```
IFAIL= 1
 On entry MX < 1,
 or MY < 1,
```

or  $PY < 8$ ,

or  $PX < 8$ .

IFAIL= 2

On entry LWRK is too small,

or LIWRK is too small.

IFAIL= 3

On entry the knots in array LAMDA, or those in array MU, are not in non-decreasing order, or  $LAMDA(PX-3) \leq LAMDA(4)$ , or  $MU(PY-3) \leq MU(4)$ .

IFAIL= 4

On entry the restriction  $LAMDA(4) \leq X(1) < \dots < X(MX) \leq LAMDA(PX-3)$ , or the restriction  $MU(4) \leq Y(1) < \dots < Y(MY) \leq MU(PY-3)$ , is violated.

## 7. Accuracy

The method used to evaluate the B-splines is numerically stable, in the sense that each computed value of  $s(x, y)$  can be regarded

$r \quad r$

as the value that would have been obtained in exact arithmetic from slightly perturbed B-spline coefficients. See Cox [2] for details.

## 8. Further Comments

Computation time is approximately proportional to  $m_x m_y + 4(m_x + m_y)$ .

## 9. Example

This program reads in knot sets  $LAMDA(1), \dots, LAMDA(PX)$  and  $MU(1), \dots, MU(PY)$ , and a set of bicubic spline coefficients  $c_{ij}$ .

$ij$

Following these are values for  $m_x$  and the  $x$  co-ordinates  $x_q$ , for

$x$

$q$

$q=1, 2, \dots, m_x$ , and values for  $m_y$  and the  $y$  co-ordinates  $y_r$ , for

$x$

$y$

$r$

$r=1, 2, \dots, m_y$ , defining the grid of points on which the spline is

$y$

to be evaluated.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

E02 -- Curve and Surface Fitting E02GAF  
 E02GAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

E02GAF calculates an  $l_1$  solution to an over-determined system of linear equations.

### 2. Specification

```

 SUBROUTINE E02GAF (M, A, LA, B, NPLUS2, TOLER, X, RESID,
1 IRANK, ITER, IWORK, IFAIL)
 INTEGER M, LA, NPLUS2, IRANK, ITER, IWORK(M),
1 IFAIL
 DOUBLE PRECISION A(LA,NPLUS2), B(M), TOLER, X(NPLUS2),
1 RESID

```

### 3. Description

Given a matrix A with m rows and n columns ( $m \geq n$ ) and a vector b with m elements, the routine calculates an  $l_1$  solution to the over-determined system of equations

$$Ax=b.$$

That is to say, it calculates a vector x, with n elements, which minimizes the  $l_1$ -norm (the sum of the absolute values) of the residuals

$$r(x) = \sum_{m=1}^n |r_m|,$$

$$\begin{matrix} & & i \\ & \text{--} & \\ i=1 & & \end{matrix}$$

where the residuals  $r_i$  are given by

$$\begin{matrix} & n \\ & \text{--} \\ r_i = b_i - \sum_{j=1}^n a_{ij} x_j, & i=1,2,\dots,m. \end{matrix}$$

Here  $a_{ij}$  is the element in row  $i$  and column  $j$  of  $A$ ,  $b_i$  is the  $i$ th element of  $b$  and  $x_j$  the  $j$ th element of  $x$ . The matrix  $A$  need not be of full rank.

Typically in applications to data fitting, data consisting of  $m$  points with co-ordinates  $(t_i, y_i)$  are to be approximated in the  $l_1$ -norm by a linear combination of known functions  $(\phi_j)(t)$ ,

$$(\alpha_1)(\phi_1)(t) + (\alpha_2)(\phi_2)(t) + \dots + (\alpha_n)(\phi_n)(t).$$

This is equivalent to fitting an  $l_1$  solution to the overdetermined system of equations

$$\begin{matrix} & n \\ & \text{--} \\ > (\phi_j)(t_i)(\alpha_j) = y_i, & i=1,2,\dots,m. \\ & \text{--} & j & i & j & i \\ & j=1 & & & & \end{matrix}$$

Thus if, for each value of  $i$  and  $j$ , the element  $a_{ij}$  of the matrix  $A$  in the previous paragraph is set equal to the value of  $(\phi_j)(t_i)$  and  $b_i$  is set equal to  $y_i$ , the solution vector  $x$  will contain the required values of the  $(\alpha_j)$ . Note that the independent variable  $t$  above can, instead, be a vector of several independent variables (this includes the case where each  $(\phi_j)$

is a function of a different variable, or set of variables).<sup>i</sup>

The algorithm is a modification of the simplex method of linear programming applied to the primal formulation of the <sup>1</sup> problem

(see Barrodale and Roberts [1] and [2]). The modification allows several neighbouring simplex vertices to be passed through in a single iteration, providing a substantial improvement in efficiency.

#### 4. References

- [1] Barrodale I and Roberts F D K (1973) An Improved Algorithm for Discrete  $\|l_1$  Linear Approximation. SIAM J. Numer. Anal. 10 839--848.<sup>1</sup>
- [2] Barrodale I and Roberts F D K (1974) Solution of an Overdetermined System of Equations in the  $\|l_1$  -norm. Comm. ACM. 17, 6 319--320.<sup>1</sup>

#### 5. Parameters

- 1: M -- INTEGER Input  
On entry: the number of equations, m (the number of rows of the matrix A). Constraint:  $M \geq n \geq 1$ .
- 2: A(LA,NPLUS2) -- DOUBLE PRECISION array Input/Output  
On entry: A(i,j) must contain a <sup>ij</sup>, the element in the ith row and jth column of the matrix A, for  $i=1,2,\dots,m$  and  $j=1,2,\dots,n$ . The remaining elements need not be set. On exit: A contains the last simplex tableau generated by the simplex method.
- 3: LA -- INTEGER Input  
On entry:  
the first dimension of the array A as declared in the (sub)program from which E02GAF is called.  
Constraint:  $LA \geq M + 2$ .
- 4: B(M) -- DOUBLE PRECISION array Input/Output  
On entry: b <sub>i</sub>, the ith element of the vector b, for  
<sub>i</sub>

$i=1,2,\dots,m$ . On exit: the  $i$ th residual  $r_i$  corresponding to the solution vector  $x$ , for  $i=1,2,\dots,m$ .

- 5: NPLUS2 -- INTEGER Input  
 On entry:  $n+2$ , where  $n$  is the number of unknowns (the number of columns of the matrix  $A$ ). Constraint:  $3 \leq \text{NPLUS2} \leq M + 2$ .
- 6: TOLER -- DOUBLE PRECISION Input  
 On entry: a non-negative value. In general TOLER specifies a threshold below which numbers are regarded as zero. The recommended threshold value is  $(\epsilon)^{2/3}$  where  $(\epsilon)$  is the machine precision. The recommended value can be computed within the routine by setting TOLER to zero. If premature termination occurs a larger value for TOLER may result in a valid solution. Suggested value: 0.0.
- 7: X(NPLUS2) -- DOUBLE PRECISION array Output  
 On exit:  $X(j)$  contains the  $j$ th element of the solution vector  $x$ , for  $j=1,2,\dots,n$ . The elements  $X(n+1)$  and  $X(n+2)$  are unused.
- 8: RESID -- DOUBLE PRECISION Output  
 On exit: the sum of the absolute values of the residuals for the solution vector  $x$ .
- 9: IRANK -- INTEGER Output  
 On exit: the computed rank of the matrix  $A$ .
- 10: ITER -- INTEGER Output  
 On exit: the number of iterations taken by the simplex method.
- 11: IWORK(M) -- INTEGER array Workspace
- 12: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

An optimal solution has been obtained but this may not be unique.

IFAIL= 2

The calculations have terminated prematurely due to rounding errors. Experiment with larger values of TOLER or try scaling the columns of the matrix (see Section 8).

IFAIL= 3

On entry NPLUS2 < 3,

or NPLUS2 > M + 2,

or LA < M + 2.

#### 7. Accuracy

Experience suggests that the computational accuracy of the solution  $x$  is comparable with the accuracy that could be obtained by applying Gaussian elimination with partial pivoting to the  $n$  equations satisfied by this algorithm (i.e., those equations with zero residuals). The accuracy therefore varies with the conditioning of the problem, but has been found generally very satisfactory in practice.

#### 8. Further Comments

The effects of  $m$  and  $n$  on the time and on the number of iterations in the Simplex Method vary from problem to problem, but typically the number of iterations is a small multiple of  $n$  and the total time taken by the routine is approximately

$$2$$

proportional to  $mn$ .

It is recommended that, before the routine is entered, the columns of the matrix  $A$  are scaled so that the largest element in each column is of the order of unity. This should improve the conditioning of the matrix, and also enable the parameter TOLER to perform its correct function. The solution  $x$  obtained will then, of course, relate to the scaled form of the matrix. Thus if the scaling is such that, for each  $j=1,2,\dots,n$ , the elements of the  $j$ th column are multiplied by the constant  $k$ , the element  $x$

of the solution vector  $x$  must be multiplied by  $k_j$  if it is desired to recover the solution corresponding to the original matrix  $A$ .

### 9. Example

Suppose we wish to approximate a set of data by a curve of the form

$$y = Ke^{t} + Le^{-t} + M$$

where  $K$ ,  $L$  and  $M$  are unknown. Given values  $y_i$  at 5 points  $t_i$  we may form the over-determined set of equations for  $K$ ,  $L$  and  $M$

$$e^{t_i} K + e^{-t_i} L + M = y_i, \quad i=1,2,\dots,5.$$

E02GAF is used to solve these in the  $l_1$  sense.

1

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E02 -- Curve and Surface Fitting

E02ZAF

E02ZAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

E02ZAF sorts two-dimensional data into rectangular panels.

### 2. Specification

```

SUBROUTINE E02ZAF (PX, PY, LAMDA, MU, M, X, Y, POINT,
1 NPOINT, ADRES, NADRES, IFAIL)
INTEGER PX, PY, M, POINT(NPOINT), NPOINT, ADRES
1 (NADRES), NADRES, IFAIL
DOUBLE PRECISION LAMDA(PX), MU(PY), X(M), Y(M)

```

### 3. Description

A set of  $m$  data points with rectangular Cartesian co-ordinates  $x, y$  are sorted into panels defined by lines parallel to the  $y$  and  $x$  axes. The intercepts of these lines on the  $x$  and  $y$  axes are given in  $LAMDA(i)$ , for  $i=5,6,\dots,PX-4$  and  $MU(j)$ , for  $j=5,6,\dots,PY-4$ , respectively. The subroutine orders the data so that all points in a panel occur before data in succeeding panels, where the panels are numbered from bottom to top and then left to right, with the usual arrangement of axes, as shown in the diagram. Within a panel the points maintain their original order.

Please see figure in printed Reference Manual

A data point lying exactly on one or more panel sides is taken to be in the highest-numbered panel adjacent to the point. The subroutine does not physically rearrange the data, but provides the array  $POINT$  which contains a linked list for each panel, pointing to the data in that panel. The total number of panels is  $(PX-7)*(PY-7)$ .

### 4. References

None.

### 5. Parameters

|                  |       |
|------------------|-------|
| 1: PX -- INTEGER | Input |
| 2: PY -- INTEGER | Input |

On entry: PX and PY must specify eight more than the number of intercepts on the  $x$  axis and  $y$  axis, respectively.  
 Constraint:  $PX \geq 8$  and  $PY \geq 8$ .

|                                        |       |
|----------------------------------------|-------|
| 3: LAMDA(PX) -- DOUBLE PRECISION array | Input |
|----------------------------------------|-------|

On entry: LAMDA(5) to LAMDA(PX-4) must contain, in non-decreasing order, the intercepts on the  $x$  axis of the sides

of the panels parallel to the y axis.

4: MU(PY) -- DOUBLE PRECISION array Input  
 On entry: MU(5) to MU(PY-4) must contain, in non-decreasing order, the intercepts on the y axis of the sides of the panels parallel to the x axis.

5: M -- INTEGER Input  
 On entry: the number m of data points.

6: X(M) -- DOUBLE PRECISION array Input

7: Y(M) -- DOUBLE PRECISION array Input  
 On entry: the co-ordinates of the rth data point ( $x_r, y_r$ ),  
r r  
 for  $r=1,2,\dots,m$ .

8: POINT(NPOINT) -- INTEGER array Output  
 On exit: for  $i = 1,2,\dots,NADRES$ , POINT(m+i) = I1 is the index of the first point in panel i, POINT(I1) = I2 is the index of the second point in panel i and so on.

POINT(IN) = 0 indicates that X(IN),Y(IN) was the last point in the panel.

The co-ordinates of points in panel i can be accessed in turn by means of the following instructions:

```

 IN = M + I
10 IN = POINT(IN)
 IF (IN.EQ. 0) GOTO 20
 XI = X(IN)
 YI = Y(IN)
 .
 .
 .
 GOTO 10
20...
```

9: NPOINT -- INTEGER Input  
 On entry:  
 the dimension of the array POINT as declared in the (sub)program from which E02ZAF is called.  
 Constraint: NPOINT  $\geq$  M + (PX-7)\*(PY-7).

10: ADRES(NADRES) -- INTEGER array Workspace

- 11: NADRES -- INTEGER Input  
 On entry: the value  $(PX-7)*(PY-7)$ , the number of panels into which the  $(x,y)$  plane is divided.
- 12: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

The intercepts in the array LAMDA, or in the array MU, are not in non-decreasing order.

IFAIL= 2

On entry  $PX < 8$ ,

or  $PY < 8$ ,

or  $M \leq 0$ ,

or  $NADRES \neq (PX-7)*(PY-7)$ ,

or  $NPOINT < M + (PX-7)*(PY-7)$ .

#### 7. Accuracy

Not applicable.

#### 8. Further Comments

The time taken by this routine is approximately proportional to  $m \cdot \log(NADRES)$ .

This subroutine was written to sort two dimensional data in the manner required by routines E02DAF and E02DBF(\*). The first 9 parameters of E02ZAF are the same as the parameters in E02DAF and

E02DBF(\*) which have the same name.

#### 9. Example

This example program reads in data points and the intercepts of the panel sides on the x and y axes; it calls E02ZAF to set up the index array POINT; and finally it prints the data points in panel order.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

(package NAGE02 NagFittingPackage)=
)abbrev package NAGE02 NagFittingPackage
++ Author: Godfrey Nolan and Mike Dewar
++ Date Created: Jan 1994
++ Date Last Updated: Thu May 12 17:44:59 1994
++ Description:
++ This package uses the NAG Library to find a
++ function which approximates a set of data points. Typically the
++ data contain random errors, as of experimental measurement, which
++ need to be smoothed out. To seek an approximation to the data, it
++ is first necessary to specify for the approximating function a
++ mathematical form (a polynomial, for example) which contains a
++ number of unspecified coefficients: the appropriate fitting
++ routine then derives for the coefficients the values which
++ provide the best fit of that particular form. The package deals
++ mainly with curve and surface fitting (i.e., fitting with
++ functions of one and of two variables) when a polynomial or a
++ cubic spline is used as the fitting function, since these cover
++ the most common needs. However, fitting with other functions
++ and/or more variables can be undertaken by means of general
++ linear or nonlinear routines (some of which are contained in
++ other packages) depending on whether the coefficients in the
++ function occur linearly or nonlinearly. Cases where a graph
++ rather than a set of data points is given can be treated simply
++ by first reading a suitable set of points from the graph.
++ The package also contains routines for evaluating,
++ differentiating and integrating polynomial and spline curves and
++ surfaces, once the numerical values of their coefficients have

## 15.5 package NAGF04 NagLinearEquationSolvingPackage

*(NagLinearEquationSolvingPackage.help)*≡

```
F04 -- Simultaneous Linear Equations Introduction -- F04
 Chapter F04
 Simultaneous Linear Equations
```

### 1. Scope of the Chapter

This chapter, together with two routines in Chapter F07, is concerned with the solution of the matrix equation  $AX=B$ , where  $B$  may be a single vector or a matrix of multiple right-hand sides. The matrix  $A$  may be real, complex, symmetric, Hermitian positive-definite, or sparse. It may also be rectangular, in which case a least-squares solution is obtained.

### 2. Background to the Problems

A set of linear equations may be written in the form

$$Ax=b$$

where the known matrix  $A$ , with real or complex coefficients, is of size  $m$  by  $n$ , ( $m$  rows and  $n$  columns), the known right-hand vector  $b$  has  $m$  components ( $m$  rows and one column), and the required solution vector  $x$  has  $n$  components ( $n$  rows and one column). There may sometimes be  $p$  vectors  $b_i$ ,  $i=1,2,\dots,p$  on the right-hand side and the equations may then be written as

$$AX=B$$

the required matrix  $X$  having as its  $p$  columns the solutions of  $Ax = b_i$ ,  $i=1,2,\dots,p$ . Some routines deal with the latter case, but for clarity only the case  $p=1$  is discussed here.

The most common problem, the determination of the unique solution of  $Ax=b$ , occurs when  $m=n$  and  $A$  is non-singular, that is  $\text{rank}(A)=n$  problem, discussed in Section 2.2 below, is the determination of the least-squares solution of  $A\tilde{x}=b$ , i.e., the determination of a vector  $x$  which minimizes the Euclidean length (two norm) of the residual vector  $r=b-Ax$ . The usual case has  $m>n$  and  $\text{rank}(A)=n$ , in

which case  $x$  is unique.

### 2.1. Unique Solution of $Ax=b$

Most of the routines in this chapter, as well as two routines in Chapter F07, solve this particular problem. The solution is obtained by performing either an LU factorization, or a Cholesky factorization, as discussed in Section 2 of the F01 Chapter Introduction.

Two of the routines in this chapter use a process called iterative refinement to improve the initial solution in order to obtain a solution that is correct to working accuracy. It should be emphasised that if  $A$  and  $b$  are not known exactly then not all the figures in this solution may be meaningful. To be more precise, if  $x$  is the exact solution of the equations

$$Ax=b$$

and  $x$  is the solution of the perturbed equations

$$(A+E)x=b+e,$$

$$\text{then, provided that } (\kappa)(A) \frac{\|E\|}{\|A\|} \leq 1,$$

$$\frac{\|x-x\|}{\|x\|} \leq \frac{(\kappa)(A)}{1-(\kappa)(A) \frac{\|E\|}{\|A\|}} \left( \frac{\|E\|}{\|A\|} + \frac{\|e\|}{\|b\|} \right),$$

where  $(\kappa)(A) = \|A\| \|A^{-1}\|$  is the condition number of  $A$  with respect to inversion. Thus, if  $A$  is ill-conditioned (

$(\kappa)(A)$  is large),  $x$  may differ significantly from  $x$ . Often

$$\kappa(A) = \frac{\|E\|}{\|A\|} < 1$$
 in which case the above bound effectively reduces to

$$\frac{\|x-x\|}{\|x\|} \leq \kappa(A) \left( \frac{\|E\|}{\|A\|} + \frac{\|e\|}{\|b\|} \right).$$

## 2.2. The Least-squares Solution of $Ax \approx b$

The least-squares problem is to find a vector  $x$  to minimize

$$\|r\|^T, \text{ where } r = b - Ax.$$

When  $m \geq n$  and  $\text{rank}(A) = n$  then the solution vector  $x$  is unique. For the cases where  $x$  is not unique the routines in this chapter obtain the minimal length solution, that is the vector  $x$  for

$$\|x\|^T$$
 which  $x$  is a minimum.

## 2.3. Calculating the Inverse of a Matrix

The routines in this chapter can also be used to calculate the inverse of a square matrix  $A$  by solving the equation

$$AX = I,$$

where  $I$  is the identity matrix.

## 3. Recommendations on Choice and Use of Routines

### 3.1. General Purpose Routines

Many of the routines in this chapter perform the complete solution of the required equations, but some of the routines, as well as the routines in Chapter F07, assume that a prior factorization has been performed, using the appropriate factorization routine from Chapter F01 or Chapter F07. These, so-called, general purpose routines can be useful when explicit information on the factorization is required, as well as the

### 15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1793

solution of the equations, or when the solution is required for multiple right-hand sides, or for a sequence of right-hand sides.

Note that some of the routines that perform a complete solution also allow multiple right-hand sides.

#### 3.2. Iterative Refinement

The routines that perform iterative refinement are more costly than those that do not perform iterative refinement, both in terms of time and storage, and should only be used if the problem really warrants the additional accuracy provided by these routines. The storage requirements are approximately doubled, while the additional time is not usually prohibitive since the initial factorization is used at each iteration.

#### 3.3. Sparse Matrix Routines

The routines for sparse matrices should usually be used only when the number of non-zero elements is very small, less than 10% of the total number of elements of A. Additionally, when the matrix is symmetric positive-definite the sparse routines should generally be used only when A does not have a (variable) band structure.

There are four routines for solving sparse linear equations, two for solving general real systems (F04AXF and F04QAF), one for solving symmetric positive-definite systems (F04MAF) and one for solving symmetric systems that may, or may not, be positive-definite (F04MBF). F04AXF and F04MAF utilise factorizations of the matrix A obtained by routines in Chapter F01, while the other two routines use iterative techniques and require a user-supplied

T

function to compute matrix-vector products  $Ac$  and  $A^T c$  for any given vector  $c$ . The routines requiring factorizations will usually be faster and the factorization can be utilised to solve for several right-hand sides, but the original matrix has to be explicitly supplied and is overwritten by the factorization, and the storage requirements will usually be substantially more than those of the iterative routines.

Routines F04MBF and F04QAF both allow the user to supply a preconditioner.

F04MBF can be used to solve systems of the form  $(A - (\lambda)I)x = b$ , which can be useful in applications such as Rayleigh quotient

iteration.

F04QAF also solves sparse least-squares problems and allows the solution of damped (regularized) least-squares problems.

### 3.4. Decision Trees

If at any stage the answer to a question is 'Don't know' this should be read as 'No'.

For those routines that need to be preceded by a factorization routine, the appropriate routine name is given in brackets after the name of the routine for solving the equations. Note also that you may be directed to a routine in Chapter F07.

#### 3.4.1. Routines for unique solution of $Ax=b$

F04 -- Simultaneous Linear Equations F04ADF  
 F04ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

F04ADF calculates the approximate solution of a set of complex linear equations with multiple right-hand sides, using an LU factorization with partial pivoting.

### 2. Specification

SUBROUTINE F04ADF (A, IA, B, IB, N, M, C, IC, WKSPCE,  
 1 IFAIL)

```

INTEGER IA, IB, N, M, IC, IFAIL
DOUBLE PRECISION WKSPACE(*)
COMPLEX(KIND(1.0D0)) A(IA,*), B(IB,*), C(IC,*)

```

### 3. Description

Given a set of complex linear equations  $AX=B$ , the routine first computes an LU factorization of A with partial pivoting,  $PA=LU$ , where P is a permutation matrix, L is lower triangular and U is unit upper triangular. The columns x of the solution X are found by forward and backward substitution in  $Ly=Pb$  and  $Ux=y$ , where b is a column of the right-hand side matrix B.

### 4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

### 5. Parameters

- 1: A(IA,\*) -- COMPLEX(KIND(1.0D)) array Input/Output  
 Note: the second dimension of the array A must be at least  $\max(1,N)$ .  
 On entry: the n by n matrix A. On exit: A is overwritten by the lower triangular matrix L and the off-diagonal elements of the upper triangular matrix U. The unit diagonal elements of U are not stored.
- 2: IA -- INTEGER Input  
 On entry:  
 the first dimension of the array A as declared in the (sub)program from which F04ADF is called.  
 Constraint:  $IA \geq \max(1,N)$ .
- 3: B(IB,\*) -- COMPLEX(KIND(1.0D)) array Input  
 Note: the second dimension of the array B must be at least  $\max(1,M)$ .  
 On entry: the n by m right-hand side matrix B. See also Section 8.
- 4: IB -- INTEGER Input  
 On entry:  
 the first dimension of the array B as declared in the (sub)program from which F04ADF is called.  
 Constraint:  $IB \geq \max(1,N)$ .

### 15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1797

- 5: N -- INTEGER Input  
On entry: n, the order of the matrix A. Constraint:  $N \geq 0$ .
- 6: M -- INTEGER Input  
On entry: m, the number of right-hand sides. Constraint:  $M \geq 0$ .
- 7: C(IC,\*) -- COMPLEX(KIND(1.0D)) array Output  
Note: the second dimension of the array C must be at least  $\max(1, M)$ .  
On exit: the n by m solution matrix X. See also Section 8.
- 8: IC -- INTEGER Input  
On entry:  
the first dimension of the array C as declared in the  
(sub)program from which F04ADF is called.  
Constraint:  $IC \geq \max(1, N)$ .
- 9: WKSPCE(\*) -- DOUBLE PRECISION array Workspace  
Note: the dimension of the array WKSPCE must be at least  $\max(1, N)$ .
- 10: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not  
familiar with this parameter (described in the Essential  
Introduction) the recommended value is 0.  
  
On exit: IFAIL = 0 unless the routine detects an error (see  
Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are  
output on the current error message unit (as defined by X04AAF).

IFAIL= 1

The matrix A is singular, possibly due to rounding errors.

IFAIL= 2

On entry  $N < 0$ ,

or  $M < 0$ ,

or  $IA < \max(1, N)$ ,

or  $IB < \max(1, N),$

or  $IC < \max(1, N).$

### 7. Accuracy

The accuracy of the computed solution depends on the conditioning of the original matrix. For a detailed error analysis see Wilkinson and Reinsch [1] page 106.

### 8. Further Comments

3

The time taken by the routine is approximately proportional to  $n$

Unless otherwise stated in the Users' Note for your implementation, the routine may be called with the same actual array supplied for parameters B and C, in which case the solution vectors will overwrite the right-hand sides. However this is not standard Fortran 77, and may not work on all systems.

### 9. Example

To solve the set of linear equations  $AX=B$  where

$$A = \begin{pmatrix} 1 & 1+2i & 2+10i \\ 1+i & 3i & -5+14i \\ 1+i & 5i & -8+20i \end{pmatrix}$$

and

$$B = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}.$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F04 -- Simultaneous Linear Equations

F04ARF

F04ARF -- NAG Foundation Library Routine Document

## 15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1799

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

F04ARF calculates the approximate solution of a set of real linear equations with a single right-hand side, using an LU factorization with partial pivoting.

### 2. Specification

```
SUBROUTINE F04ARF (A, IA, B, N, C, WKSPCE, IFAIL)
 INTEGER IA, N, IFAIL
 DOUBLE PRECISION A(IA,*), B(*), C(*), WKSPCE(*)
```

### 3. Description

Given a set of linear equations,  $Ax=b$ , the routine first computes an LU factorization of A with partial pivoting,  $PA=LU$ , where P is a permutation matrix, L is lower triangular and U is unit upper triangular. The approximate solution x is found by forward and backward substitution in  $Ly=Pb$  and  $Ux=y$ , where b is the right-hand side.

### 4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

### 5. Parameters

- 1: A(IA,\*) -- DOUBLE PRECISION array Input/Output  
Note: the second dimension of the array A must be at least  $\max(1,N)$ .  
On entry: the n by n matrix A. On exit: A is overwritten by the lower triangular matrix L and the off-diagonal elements of the upper triangular matrix U. The unit diagonal elements of U are not stored.
- 2: IA -- INTEGER Input  
On entry:  
the first dimension of the array A as declared in the (sub)program from which F04ARF is called.  
Constraint:  $IA \geq \max(1,N)$ .

- 3: B(\*) -- DOUBLE PRECISION array Input  
 Note: the dimension of the array B must be at least  $\max(1,N)$ .  
 On entry: the right-hand side vector b.
- 4: N -- INTEGER Input  
 On entry: n, the order of the matrix A. Constraint:  $N \geq 0$ .
- 5: C(\*) -- DOUBLE PRECISION array Output  
 Note: the dimension of the array C must be at least  $\max(1,N)$ .  
 On exit: the solution vector x.
- 6: WKSPCE(\*) -- DOUBLE PRECISION array Workspace  
 Note: the dimension of the array WKSPCE must be at least  $\max(1,N)$ .
- 7: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

The matrix A is singular, possibly due to rounding errors.

IFAIL= 2

On entry  $N < 0$ ,

or  $IA < \max(1,N)$ .

## 7. Accuracy

The accuracy of the computed solution depends on the conditioning of the original matrix. For a detailed error analysis see Wilkinson and Reinsch [1] page 107.

## 8. Further Comments

3

The time taken by the routine is approximately proportional to  $n$

Unless otherwise stated in the Users' Note for your implementation, the routine may be called with the same actual array supplied for parameters B and C, in which case the solution vector will overwrite the right-hand side. However this is not standard Fortran 77, and may not work on all systems.

## 9. Example

To solve the set of linear equations  $Ax=b$  where

$$A = \begin{pmatrix} 33 & 16 & 72 \\ -24 & -10 & -57 \\ -8 & -4 & -17 \end{pmatrix}$$

and

$$b = \begin{pmatrix} -359 \\ 281 \\ 85 \end{pmatrix}.$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

F04 -- Simultaneous Linear Equations F04ASF  
F04ASF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

F04ASF calculates the accurate solution of a set of real symmetric positive-definite linear equations with a single right-hand side,  $Ax=b$ , using a Cholesky factorization and iterative

refinement.

## 2. Specification

```

SUBROUTINE F04ASF (A, IA, B, N, C, WK1, WK2, IFAIL)
 INTEGER IA, N, IFAIL
 DOUBLE PRECISION A(IA,*), B(*), C(*), WK1(*), WK2(*)

```

## 3. Description

Given a set of real linear equations  $Ax=b$ , where  $A$  is a symmetric positive-definite matrix, the routine first computes a Cholesky

$T$   
factorization of  $A$  as  $A=LL^T$  where  $L$  is lower triangular. An approximation to  $x$  is found by forward and backward substitution. The residual vector  $r=b-Ax$  is then calculated using additional

$T$   
precision and a correction  $d$  to  $x$  is found by solving  $LL^T d=r$ .  $x$  is then replaced by  $x+d$ , and this iterative refinement of the solution is repeated until machine accuracy is obtained.

## 4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

## 5. Parameters

- 1:  $A(IA,*)$  -- DOUBLE PRECISION array Input/Output  
 Note: the second dimension of the array  $A$  must be at least  $\max(1,N)$ .  
 On entry: the upper triangle of the  $n$  by  $n$  positive-definite symmetric matrix  $A$ . The elements of the array below the diagonal need not be set. On exit: the elements of the array below the diagonal are overwritten; the upper triangle of  $A$  is unchanged.
- 2:  $IA$  -- INTEGER Input  
 On entry:  
 the first dimension of the array  $A$  as declared in the (sub)program from which F04ASF is called.  
 Constraint:  $IA \geq \max(1,N)$ .
- 3:  $B(*)$  -- DOUBLE PRECISION array Input  
 Note: the dimension of the array  $B$  must be at least  $\max(1,N)$ .

### 15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1803

On entry: the right-hand side vector b.

- 4: N -- INTEGER Input  
On entry: n, the order of the matrix A. Constraint:  $N \geq 0$ .
- 5: C(\*) -- DOUBLE PRECISION array Output  
Note: the dimension of the array C must be at least  $\max(1, N)$ .  
On exit: the solution vector x.
- 6: WK1(\*) -- DOUBLE PRECISION array Workspace  
Note: the dimension of the array WK1 must be at least  $\max(1, N)$ .
- 7: WK2(\*) -- DOUBLE PRECISION array Workspace  
Note: the dimension of the array WK2 must be at least  $\max(1, N)$ .
- 8: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

The matrix A is not positive-definite, possibly due to rounding errors.

IFAIL= 2

Iterative refinement fails to improve the solution, i.e., the matrix A is too ill-conditioned.

IFAIL= 3

On entry  $N < 0$ ,

or  $IA < \max(1, N)$ .

## 7. Accuracy

The computed solutions should be correct to full machine accuracy. For a detailed error analysis see Wilkinson and Reinsch [1] page 39.

## 8. Further Comments

3

The time taken by the routine is approximately proportional to  $n$

The routine must not be called with the same name for parameters B and C.

## 9. Example

To solve the set of linear equations  $Ax=b$  where

$$A = \begin{pmatrix} 5 & 7 & 6 & 5 \\ 7 & 10 & 8 & 7 \\ 6 & 8 & 10 & 9 \\ 5 & 7 & 9 & 10 \end{pmatrix}$$

and

$$b = \begin{pmatrix} 23 \\ 32 \\ 33 \\ 31 \end{pmatrix}.$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F04ATF

F04ATF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

## 15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1805

F04ATF calculates the accurate solution of a set of real linear equations with a single right-hand side, using an LU factorization with partial pivoting, and iterative refinement.

### 2. Specification

```
SUBROUTINE F04ATF (A, IA, B, N, C, AA, IAA, WKS1, WKS2,
1 IFAIL)
 INTEGER IA, N, IAA, IFAIL
 DOUBLE PRECISION A(IA,*), B(*), C(*), AA(IAA,*), WKS1(*),
1 WKS2(*)
```

### 3. Description

Given a set of real linear equations,  $Ax=b$ , the routine first computes an LU factorization of A with partial pivoting,  $PA=LU$ , where P is a permutation matrix, L is lower triangular and U is unit upper triangular. An approximation to x is found by forward and backward substitution in  $Ly=Pb$  and  $Ux=y$ . The residual vector  $r=b-Ax$  is then calculated using additional precision, and a correction d to x is found by solving  $LUd=r$ . x is replaced by  $x+d$ , and this iterative refinement of the solution is repeated until full machine accuracy is obtained.

### 4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

### 5. Parameters

- 1: A(IA,\*) -- DOUBLE PRECISION array Input  
Note: the second dimension of the array A must be at least  $\max(1,N)$ .  
On entry: the n by n matrix A.
- 2: IA -- INTEGER Input  
On entry:  
the first dimension of the array A as declared in the (sub)program from which F04ATF is called.  
Constraint:  $IA \geq \max(1,N)$ .
- 3: B(\*) -- DOUBLE PRECISION array Input  
Note: the dimension of the array B must be at least  $\max(1,N)$ .

On entry: the right-hand side vector *b*.

- 4: *N* -- INTEGER Input  
 On entry: *n*, the order of the matrix *A*. Constraint:  $N \geq 0$ .
  
- 5: *C*(\*) -- DOUBLE PRECISION array Output  
 Note: the dimension of the array *C* must be at least  $\max(1, N)$ .  
 On exit: the solution vector *x*.
  
- 6: *AA*(*IAA*,\*) -- DOUBLE PRECISION array Output  
 Note: the second dimension of the array *AA* must be at least  $\max(1, N)$ .  
 On exit: the triangular factors *L* and *U*, except that the unit diagonal elements of *U* are not stored.
  
- 7: *IAA* -- INTEGER Input  
 On entry:  
 the first dimension of the array *AA* as declared in the  
 (sub)program from which F04ATF is called.  
 Constraint:  $IAA \geq \max(1, N)$ .
  
- 8: *WKS1*(\*) -- DOUBLE PRECISION array Workspace  
 Note: the dimension of the array *WKS1* must be at least  $\max(1, N)$ .
  
- 9: *WKS2*(\*) -- DOUBLE PRECISION array Workspace  
 Note: the dimension of the array *WKS2* must be at least  $\max(1, N)$ .
  
- 10: *IFAIL* -- INTEGER Input/Output  
 On entry: *IFAIL* must be set to 0, -1 or 1. For users not  
 familiar with this parameter (described in the Essential  
 Introduction) the recommended value is 0.  
  
 On exit: *IFAIL* = 0 unless the routine detects an error (see  
 Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry *IFAIL* = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

*IFAIL* = 1

### 15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1807

The matrix A is singular, possibly due to rounding errors.

IFAIL= 2

Iterative refinement fails to improve the solution, i.e.,  
the matrix A is too ill-conditioned.

IFAIL= 3

On entry N < 0,

or IA < max(1,N),

or IAA < max(1,N).

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

F04 -- Simultaneous Linear Equations F04AXF  
 F04AXF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

F04AXF calculates the approximate solution of a set of real sparse linear equations with a single right-hand side,  $Ax=b$  or  $A^T x=b$ , where  $A$  has been factorized by F01BRF or F01BSF.

### 2. Specification

```

 SUBROUTINE F04AXF (N, A, LICN, ICN, IKEEP, RHS, W, MTYPE,
1 IDISP, RESID)
 INTEGER N, LICN, ICN(LICN), IKEEP(5*N), MTYPE,
1 IDISP(2)
 DOUBLE PRECISION A(LICN), RHS(N), W(N), RESID
```

### 3. Description

To solve a system of real linear equations  $Ax=b$  or  $A^T x=b$ , where  $A$  is a general sparse matrix,  $A$  must first be factorized by F01BRF or F01BSF. F04AXF then computes  $x$  by block forward or backward substitution using simple forward and backward substitution within each diagonal block.

The method is fully described in Duff [1].

### 4. References

- [1] Duff I S (1977) MA28 -- a set of Fortran subroutines for sparse unsymmetric linear equations. A.E.R.E. Report R.8730. HMSO.

### 5. Parameters

1: N -- INTEGER Input

## 15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1809

On entry: n, the order of the matrix A.

- ```

2:  A(LICN) -- DOUBLE PRECISION array                                Input
    On entry: the non-zero elements in the factorization of the
    matrix A, as returned by F01BRF or F01BSF.

3:  LICN -- INTEGER                                                  Input
    On entry:
    the dimension of the arrays A and ICN as declared in the
    (sub)program from which F04AXF is called.

4:  ICN(LICN) -- INTEGER array                                       Input
    On entry: the column indices of the non-zero elements of
    the factorization, as returned by F01BRF or F01BSF.

5:  IKEEP(5*N) -- INTEGER array                                     Input
    On entry: the indexing information about the factorization,
    as returned by F01BRF or F01BSF.

6:  RHS(N) -- DOUBLE PRECISION array                                Input/Output
    On entry: the right-hand side vector b. On exit: RHS is
    overwritten by the solution vector x.

7:  W(N) -- DOUBLE PRECISION array                                   Workspace

8:  MTYPE -- INTEGER                                                  Input
    On entry: MTYPE specifies the task to be performed:
        if MTYPE = 1, solve  $Ax=b$ ,
                                T
        if MTYPE /= 1, solve  $A^T x=b$ .

9:  IDISP(2) -- INTEGER array                                         Input
    On entry: the values returned in IDISP by F01BRF.

10: RESID -- DOUBLE PRECISION                                         Output
    On exit: the value of the maximum residual,
        --
         $\max(|b - \sum_j a_{ij} x_j|)$ , over all the unsatisfied equations, in
        i -- ij j
        case F01BRF or F01BSF has been used to factorize a singular
        or rectangular matrix.

```

6. Error Indicators and Warnings

None.

7. Accuracy

The accuracy of the computed solution depends on the conditioning of the original matrix. Since F04AXF is always used with either F01BRF or F01BSF, the user is recommended to set GROW = .TRUE. on entry to these routines and to examine the value of W(1) on exit (see the routine documents for F01BRF and F01BSF). For a detailed error analysis see Duff [1] page 17.

If storage for the original matrix is available then the error can be estimated by calculating the residual

$$r = b - Ax^T \quad (\text{or } b - A x)$$

and calling F04AXF again to find a correction (delta) for x by solving

$$A(\delta) = r^T \quad (\text{or } A(\delta) = r).$$

8. Further Comments

If the factorized form contains (tau) non-zeros (IDISP(2) = (tau)) then the time taken is very approximately 2(tau) times longer than the inner loop of full matrix code. Some advantage is taken

of zeros in the right-hand side when solving $Ax = b$ (MTYPE /= 1).

9. Example

To solve the set of linear equations $Ax = b$ where

$$A = \begin{pmatrix} 5 & 0 & 0 & 0 & 0 & 0 \\ 0 & 2 & -1 & 2 & 0 & 0 \\ 0 & 0 & 3 & 0 & 0 & 0 \\ -2 & 0 & 0 & 1 & 1 & 0 \\ -1 & 0 & 0 & -1 & 2 & -3 \\ -1 & -1 & 0 & 0 & 0 & 6 \end{pmatrix}$$

and

15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1811

```
(12)
(18)
b=( 3).
(-6)
( 0)
```

The non-zero elements of A and indexing information are read in by the program, as described in the document for F01BRF.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

```

```

```
F04 -- Simultaneous Linear Equations                                F04FAF
      F04FAF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F04FAF calculates the approximate solution of a set of real symmetric positive-definite tridiagonal linear equations.

2. Specification

```
SUBROUTINE F04FAF (JOB, N, D, E, B, IFAIL)
  INTEGER          JOB, N, IFAIL
  DOUBLE PRECISION D(N), E(N), B(N)
```

3. Description

F04FAF is based upon the Linpack routine DPTSL (see Dongarra et al [1]) and solves the equations

$$Tx=b,$$

where T is a real n by n symmetric positive-definite tridiagonal matrix, using a modified symmetric Gaussian elimination algorithm

T

to factorize T as $T=MKM^T$, where K is diagonal and M is a matrix of multipliers as described in Section 8.

When the input parameter JOB is supplied as 1, then the routine assumes that a previous call to F04FAF has already factorized T; otherwise JOB must be supplied as 0.

4. References

- [1] Dongarra J J, Moler C B, Bunch J R and Stewart G W (1979) LINPACK Users' Guide. SIAM, Philadelphia.

5. Parameters

- 1: JOB -- INTEGER Input
 On entry: specifies the job to be performed by F04FAF as follows:
 JOB = 0
 The matrix T is factorized and the equations $Tx=b$ are solved for x.

 JOB = 1
 The matrix T is assumed to have already been factorized by a previous call to F04FAF with JOB = 0; the equations $Tx=b$ are solved for x.
- 2: N -- INTEGER Input
 On entry: n, the order of the matrix T. Constraint: $N \geq 1$.
- 3: D(N) -- DOUBLE PRECISION array Input/Output
 On entry: if JOB = 0, D must contain the diagonal elements of T. If JOB = 1, D must contain the diagonal matrix K, as returned by a previous call of F04FAF with JOB = 0. On exit: if JOB = 0, D is overwritten by the diagonal matrix K of the factorization. If JOB = 1, D is unchanged.
- 4: E(N) -- DOUBLE PRECISION array Input/Output
 On entry: if JOB = 0, E must contain the super-diagonal elements of T, stored in E(2) to E(n). If JOB = 1, E must contain the off-diagonal elements of the matrix M, as returned by a previous call of F04FAF with JOB = 0. E(1) is not used. On exit: if JOB = 0, E(2) to E(n) are overwritten by the off-diagonal elements of the matrix M of the factorization. If JOB = 1, E is unchanged.
- 5: B(N) -- DOUBLE PRECISION array Input/Output
 On entry: the right-hand side vector b. On exit: B is overwritten by the solution vector x.

6: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

On entry $N < 1$,

or $JOB \neq 0$ or 1.

IFAIL= 2

The matrix T is either not positive-definite or is nearly singular. This failure can only occur when $JOB = 0$ and inspection of the elements of D will give an indication of why failure has occurred. If an element of D is close to zero, then T is probably nearly singular; if an element of D is negative but not close to zero, then T is not positive-definite.

IFAILOverflow

If overflow occurs during the execution of this routine, then either T is very nearly singular or an element of the right-hand side vector b is very large. In this latter case the equations should be scaled so that no element of b is very large. Note that to preserve symmetry it is necessary

T

to scale by a transformation of the form $(PTP^T)b = Px$, where P is a diagonal matrix.

IFAILUnderflow

Any underflows that occur during the execution of this routine are harmless.

7. Accuracy

The computed factorization (see Section 8) will satisfy the equation

$$T \\ MKM = T + E$$

where $\|E\|_p \leq 2(\epsilon) \|T\|_p$, $p=1, F, \infty$,

(ϵ) being the machine precision. The computed solution of

the equations $Tx=b$, say x , will satisfy an equation of the form

$$(T+F)x=b,$$

where F can be expected to satisfy a bound of the form

$$\|F\| \leq (\alpha)(\epsilon) \|T\|,$$

(α) being a modest constant. This implies that the relative

error in x satisfies

$$\frac{\|x-x\|}{\|x\|} \leq c(T)(\alpha)(\epsilon),$$

where $c(T)$ is the condition number of T with respect to

inversion. Thus if T is nearly singular, x can be expected to have a large relative error.

8. Further Comments

The time taken by the routine is approximately proportional to n .

The routine eliminates the off-diagonal elements of T by simultaneously performing symmetric Gaussian elimination from the top and the bottom of T . The result is that T is factorized as

$$T \\ T = MKM,$$

15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1815

where K is a diagonal matrix and M is a matrix of the form

$$M = \begin{pmatrix} 1 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 & 0 \\ m & 1 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 & 0 \\ (2 & & & & & & & & & & \\ 0 & m & 1 & \dots & 0 & 0 & 0 & \dots & 0 & 0 & 0 \\ (3 & & & & & & & & & & \\ . & . & . & \dots & . & . & . & \dots & . & . & . \\ . & . & . & \dots & . & . & . & \dots & . & . & . \\ 0 & 0 & 0 & \dots & 1 & 0 & 0 & \dots & 0 & 0 & 0 \\ (0 & 0 & 0 & \dots & m & 1 & m & \dots & 0 & 0 & 0 \\ (j+1 & & & & & & & & & & \\ 0 & 0 & 0 & \dots & 0 & 0 & \dots & 1 & 0 & 0 & 0 \\ . & . & . & \dots & . & . & . & \dots & . & . & . \\ . & . & . & \dots & . & . & . & \dots & . & . & . \\ 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 1 & m & 0 \\ (n-1 & & & & & & & & & & \\ 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 1 & m \\ (n & & & & & & & & & & \\ 0 & 0 & 0 & \dots & 0 & 0 & 0 & \dots & 0 & 0 & 1 \end{pmatrix}$$

j being the integer part of $n/2$. (For example when $n=5, j=2$.) The diagonal elements of K are returned in D with k_i in the i th element of D and m_i is returned in the i th element of E.

The routine fails with IFAIL = 2 if any diagonal element of K is non-positive. It should be noted that T may be nearly singular even if all the diagonal elements of K are positive, but in this case at least one element of K is almost certain to be small relative to $|||T|||$. If there is any doubt as to whether or not T is nearly singular, then the user should consider examining the diagonal elements of K.

9. Example

To solve the symmetric positive-definite equations

$$Tx = b$$

and

$$Tx = b$$

2 2

where

$$\begin{array}{rcl}
 \begin{pmatrix} 4 & -2 & 0 & 0 & 0 \\ -2 & 10 & -6 & 0 & 0 \\ 0 & -6 & 29 & 15 & 0 \\ 0 & 0 & 15 & 25 & 8 \\ 0 & 0 & 0 & 8 & 5 \end{pmatrix} & \begin{pmatrix} 6 \\ 9 \\ 2 \\ 14 \\ 7 \end{pmatrix} & \begin{pmatrix} 10 \\ 4 \\ 9 \\ 65 \\ 23 \end{pmatrix} \\
 T = & b = & b = \\
 \end{array}$$

The equations are solved by two calls to F04FAF, the first with JOB = 0 and the second, using the factorization from the first call, with JOB = 1.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F04 -- Simultaneous Linear Equations F04JGF
 F04JGF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F04JGF finds the solution of a linear least-squares problem, $Ax=b$, where A is a real m by n ($m \geq n$) matrix and b is an m element vector. If the matrix of observations is not of full rank, then the minimal least-squares solution is returned.

2. Specification

```

SUBROUTINE F04JGF (M, N, A, NRA, B, TOL, SVD, SIGMA,
1                IRANK, WORK, LWORK, IFAIL)
  INTEGER          M, N, NRA, IRANK, LWORK, IFAIL
  DOUBLE PRECISION A(NRA,N), B(M), TOL, SIGMA, WORK(LWORK)
  LOGICAL          SVD

```

3. Description

The minimal least-squares solution of the problem $Ax=b$ is the

15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1817

vector x of minimum (Euclidean) length which minimizes the length of the residual vector $r=b-Ax$.

The real m by n ($m \geq n$) matrix A is factorized as

$$\begin{pmatrix} U \\ 0 \end{pmatrix} \\ A=Q \begin{pmatrix} 0 \\ I \end{pmatrix}$$

where Q is an m by m orthogonal matrix and U is an n by n upper triangular matrix. If U is of full rank, then the least-squares solution is given by

$$x=(U^{-1} \quad 0)^T Q^T b.$$

If U is not of full rank, then the singular value decomposition of U is obtained so that U is factorized as

$$U=RD P^T,$$

where R and P are n by n orthogonal matrices and D is the n by n diagonal matrix

$$D=\text{diag}((\sigma_1), (\sigma_2), \dots, (\sigma_n)),$$

with $(\sigma_1) \geq (\sigma_2) \geq \dots (\sigma_n) \geq 0$, these being the singular values of A . If the singular values $(\sigma_{k+1}), \dots, (\sigma_n)$ are negligible, but (σ_k) is not negligible, relative to the data errors in A , then the rank of A is taken to be k and the minimal least-squares solution is given by

$$\begin{pmatrix} -1 \\ S \end{pmatrix} \begin{pmatrix} T \\ 0 \end{pmatrix} \\ x=P \begin{pmatrix} 0 & 0 \\ 0 & I \end{pmatrix} Q^T b,$$

where $S=\text{diag}((\sigma_1), (\sigma_2), \dots, (\sigma_k))$.

This routine obtains the factorizations by a call to F02WDF(*).

The routine also returns the value of the standard error

$$\begin{aligned}
 (\text{sigma}) &= \begin{array}{c} / \quad T \\ / \quad r \quad r \\ / \quad \text{---} \\ \backslash \quad m-k \end{array}, & \text{if } m > k, \\
 &= 0, & \text{if } m = k, \text{ } r \text{ } r \text{ being the residual sum of} \\
 & & \text{squares and } k \text{ the rank of } A.
 \end{aligned}$$

4. References

- [1] Lawson C L and Hanson R J (1974) Solving Least-squares Problems. Prentice-Hall.

5. Parameters

- 1: M -- INTEGER Input
On entry: m, the number of rows of A. Constraint: M ≥ N.
- 2: N -- INTEGER Input
On entry: n, the number of columns of A. Constraint: 1 ≤ N ≤ M.
- 3: A(NRA,N) -- DOUBLE PRECISION array Input/Output
On entry: the m by n matrix A. On exit: if SVD is returned as .FALSE., A is overwritten by details of the QU factorization of A (see F02WDF(*) for further details). If SVD is returned as .TRUE., the first n rows of A are overwritten by the right-hand singular vectors, stored by rows; and the remaining rows of the array are used as workspace.
- 4: NRA -- INTEGER Input
On entry:
the first dimension of the array A as declared in the (sub)program from which F04JGF is called.
Constraint: NRA ≥ M.
- 5: B(M) -- DOUBLE PRECISION array Input/Output
On entry: the right-hand side vector b. On exit: the first n elements of B contain the minimal least-squares solution vector x. The remaining m-n elements are used for workspace.
- 6: TOL -- DOUBLE PRECISION Input

15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1819

On entry: a relative tolerance to be used to determine the rank of A. TOL should be chosen as approximately the largest relative error in the elements of A. For example, if the elements of A are correct to about 4 significant figures

-4

then TOL should be set to about 5×10^{-4} . See Section 8 for a description of how TOL is used to determine rank. If TOL is outside the range $((\text{epsilon}), 1.0)$, where (epsilon) is the machine precision, then the value (epsilon) is used in place of TOL. For most problems this is unreasonably small.

7: SVD -- LOGICAL Output

On exit: SVD is returned as .FALSE. if the least-squares solution has been obtained from the QU factorization of A. In this case A is of full rank. SVD is returned as .TRUE. if the least-squares solution has been obtained from the singular value decomposition of A.

8: SIGMA -- DOUBLE PRECISION Output

/ T

On exit: the standard error, i.e., the value $\sqrt{r/(m-k)}$ when $m > k$, and the value zero when $m = k$. Here r is the residual vector $b - Ax$ and k is the rank of A.

9: IRANK -- INTEGER Output

On exit: k , the rank of the matrix A. It should be noted that it is possible for IRANK to be returned as n and SVD to be returned as .TRUE.. This means that the matrix U only just failed the test for non-singularity.

10: WORK(LWORK) -- DOUBLE PRECISION array Output

On exit: if SVD is returned as .FALSE., then the first n elements of WORK contain information on the QU factorization of A (see parameter A above and F02WDF(*)), and $\text{WORK}(n+1)$

-1

contains the condition number $\frac{\|U\|}{\|U\|_E}$ of the upper triangular matrix U.

If SVD is returned as .TRUE., then the first n elements of WORK contain the singular values of A arranged in descending order and $\text{WORK}(n+1)$ contains the total number of iterations taken by the QR algorithm. The rest of WORK is used as workspace.

11: LWORK -- INTEGER Input
 On entry:
 the dimension of the array WORK as declared in the
 (sub)program from which F04JGF is called.
 Constraint: LWORK $\geq 4*N$.

12: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not
 familiar with this parameter (described in the Essential
 Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
 Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

On entry $N < 1$,

or $M < N$,

or $NRA < M$,

or $LWORK < 4*N$.

IFAIL= 2

The QR algorithm has failed to converge to the singular
 values in $50*N$ iterations. This failure can only happen when
 the singular value decomposition is employed, but even then
 it is not likely to occur.

7. Accuracy

The computed factors Q , U , R , D and P^T satisfy the relations

$$\begin{pmatrix} U \\ Q \end{pmatrix} \begin{pmatrix} R & 0 \\ 0 & I \end{pmatrix} \begin{pmatrix} D \\ 0 \end{pmatrix} P^T = A + F,$$

where

$$\|E\|_2 \leq c(\epsilon) \|A\|_2,$$

$$\|F\|_2 \leq c(\epsilon) \|A\|_2,$$

(epsilon) being the machine precision, and c_1 and c_2 being modest functions of m and n . Note that $\|A\|_2 = (\sigma_1)$.

For a fuller discussion, covering the accuracy of the solution x see Lawson and Hanson [1], especially pp 50 and 95.

8. Further Comments

If the least-squares solution is obtained from the QU factorization then the time taken by the routine is approximately proportional to $n^2(3m-n)$. If the least-squares solution is obtained from the singular value decomposition then the time taken is approximately proportional to $n^2(3m+19n)$. The approximate proportionality factor is the same in each case.

This routine is column biased and so is suitable for use in paged environments.

Following the QU factorization of A the condition number

$$c(U) = \frac{\|U\|_E^{-1}}{\|U\|_E}$$

is determined and if $c(U)$ is such that

$$c(U) * TOL > 1.0$$

then U is regarded as singular and the singular values of A are computed. If this test is not satisfied, U is regarded as non-singular and the rank of A is set to n . When the singular values are computed the rank of A , say k , is returned as the largest integer such that

$$(\sigma_k) > TOL * (\sigma_1),$$

unless $(\sigma_i) = 0$ in which case k is returned as zero. That is,
 singular values which satisfy $(\sigma_i) \leq \text{TOL} * (\sigma_1)$ are regarded
 as negligible because relative perturbations of order TOL can
 make such singular values zero.

9. Example

To obtain a least-squares solution for $r=b-Ax$, where

$$\begin{array}{rr} (0.05 & 0.05 & 0.25 & -0.25) & (1) \\ (0.25 & 0.25 & 0.05 & -0.05) & (2) \\ (0.35 & 0.35 & 1.75 & -1.75) & (3) \\ A=(1.75 & 1.75 & 0.35 & -0.35), & B=(4) \\ (0.30 & -0.30 & 0.30 & 0.30) & (5) \\ (0.40 & -0.40 & 0.40 & 0.40) & (6) \end{array}$$

and the value TOL is to be taken as 5×10^{-4} .

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F04 -- Simultaneous Linear Equations F04MAF
 F04MAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

To solve a sparse symmetric positive-definite system of linear equations, $Ax=b$, using a pre-conditioned conjugate gradient method, where A has been factorized by F01MAF.

2. Specification

```

      SUBROUTINE F04MAF (N, NZ, A, LICN, IRN, LIRN, ICN, B, ACC,
1      NOITS, WKEEP, WORK, IKEEP, INFORM,
2      IFAIL)
```

15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1823

```

      INTEGER          N, NZ, LICN, IRN(LIRN), LIRN, ICN(LICN),
1                     NOITS(2), IKEEP(2*N), INFORM(4), IFAIL
      DOUBLE PRECISION A(LICN), B(N), ACC(2), WKEEP(3*N), WORK
1                     (3*N)

```

3. Description

F04MAF solves the n linear equations

$$Ax=b, \quad (1)$$

where A is a sparse symmetric positive-definite matrix, following the incomplete Cholesky factorization by F01MAF, given by

$$C = PLDL^T P^T, \quad WAW = C + E,$$

where P is a permutation matrix, L is a unit lower triangular matrix, D is a diagonal matrix with positive diagonal elements, E is an error matrix representing elements dropped during the factorization and diagonal elements that have been modified to ensure that C is positive-definite, and W is a diagonal matrix, chosen to make the diagonal elements of WAW unity.

Equation (1) is solved by applying a pre-conditioned conjugate gradient method to the equations

$$(WAW)(W^{-1}x) = Wb, \quad (2)$$

using C as the pre-conditioning matrix. Details of the conjugate gradient method are given in Munksgaard [1].

The iterative procedure is terminated if

$$\frac{\|Wr\|}{2} \leq (\text{eta}), \quad (3)$$

where r is the residual vector $r=b-Ax$, $\|r\|$ denotes the Euclidean length of r , (eta) is a user-supplied tolerance and x is the current approximation to the solution. Notice that

$$Wr = Wb - (WAW)(W^{-1}x)$$

so that W_r is the residual of the normalised equations (2).

F04MAF is based on the Harwell Library routine MA31B.

4. References

- [1] Munksgaard N (1980) Solving Sparse Symmetric Sets of Linear Equations by Pre-conditioned Conjugate Gradients. ACM Trans. Math. Softw. 6 206--219.

5. Parameters

- 1: N -- INTEGER Input
On entry: n, the order of the matrix A. Constraint: $N \geq 1$.
- 2: NZ -- INTEGER Input
On entry: the number of non-zero elements in the upper triangular part of the matrix A, including the number of elements on the leading diagonal. Constraint: $NZ \geq N$.
- 3: A(LICN) -- DOUBLE PRECISION array Input
On entry: the first LROW elements, where LROW is the value supplied in INFORM(1), must contain details of the factorization, as returned by F01MAF.
- 4: LICN -- INTEGER Input
On entry: the length of the array A, as declared in the (sub)program from which F04MAF is called. It need never be larger than the value of LICN supplied to F01MAF.
Constraint: $LICN \geq \text{INFORM}(1)$.
- 5: IRN(LIRN) -- INTEGER array Input
On entry: the first LCOL elements, where LCOL is the value supplied in INFORM(2), must contain details of the factorization, as returned by F01MAF.
- 6: LIRN -- INTEGER Input
On entry: the length of the array IRN, as declared in the (sub)program from which F04MAF is called. It need never be larger than the value of LIRN supplied to F01MAF.
Constraint: $LIRN \geq \text{INFORM}(2)$.
- 7: ICN(LICN) -- INTEGER array Input
On entry: the first LROW elements, where LROW is the value supplied in INFORM(1), must contain details of the factorization, as returned by F01MAF.

15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1825

- 8: B(N) -- DOUBLE PRECISION array Input/Output
 On entry: the right-hand side vector b. On exit: B is
 overwritten by the solution vector x.

- 9: ACC(2) -- DOUBLE PRECISION array Input/Output
 On entry: ACC(1) specifies the tolerance for convergence,
 (eta), in equation (3) of Section 3. If ACC(1) is outside
 the range [(epsilon),1], where (epsilon) is the machine
 precision, then the value (epsilon) is used in place of ACC
 (1). ACC(2) need not be set. On exit: ACC(2) contains the
 actual value of $\|Wr\|_2$ at the final point. ACC(1) is
 unchanged.

- 10: NOITS(2) -- INTEGER array Input/Output
 On entry: NOITS(1) specifies the maximum permitted number of
 iterations. If NOITS(1) < 1, then the value 100 is used in
 its place. NOITS(2) need not be set. On exit: NOITS(2)
 contains the number of iterations taken to converge. NOITS
 (1) is unchanged.

- 11: WKEEP(3*N) -- DOUBLE PRECISION array Input
 On entry: WKEEP must be unchanged from the previous call of
 F01MAF.

- 12: WORK(3*N) -- DOUBLE PRECISION array Output
 On exit: WORK(1) contains a lower bound for the condition
 number of A. The rest of the array is used for workspace.

- 13: IKEEP(2*N) -- INTEGER array Input
 On entry: IKEEP must be unchanged from the previous call of
 F01MAF.

- 14: INFORM(4) -- INTEGER array Input
 On entry: INFORM must be unchanged from the previous call of
 F01MAF.

- 15: IFAIL -- INTEGER Input/Output
 For this routine, the normal use of IFAIL is extended to
 control the printing of error and warning messages as well
 as specifying hard or soft failure (see the Essential
 Introduction).

Before entry, IFAIL must be set to a value with the decimal
 expansion cba, where each of the decimal digits c, b and a

must have a value of 0 or 1.

a=0 specifies hard failure, otherwise soft failure;

b=0 suppresses error messages, otherwise error messages will be printed (see Section 6);

c=0 suppresses warning messages, otherwise warning messages will be printed (see Section 6).

The recommended value for inexperienced users is 110 (i.e., hard failure with all messages printed).

Unless the routine detects an error (see Section 6), IFAIL contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

For each error, an explanatory error message is output on the current error message unit (as defined by X04AAF), unless suppressed by the value of IFAIL on entry.

IFAIL= 1

On entry $N < 1$,

or $NZ < N$,

or $LICN < INFORM(1)$,

or $LIRN < INFORM(2)$.

IFAIL= 2

Convergence has not taken place within the requested NOITS (1) number of iterations. ACC(2) gives the value $\|Wr\|_2$ for the final point. Either too few iterations have been allowed, or the requested convergence criterion cannot be met.

IFAIL= 3

The matrix A is singular, or nearly singular. Singularity has been detected during the conjugate gradient iterations, so that the computations are not complete.

IFAIL= 4

The matrix A is singular, or nearly singular. The message

15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1827

output on the current error message channel will include an estimate of the condition number of A. In the case of soft failure an approximate solution is returned such that the value $\|Wr\|_2$ is given by ACC(2) and the estimate (a lower bound) of the condition number is returned in WORK(1).

7. Accuracy

On successful return, or on return with IFAIL = 2 or IFAIL = 4 the computed solution will satisfy equation (3) of Section 3, with $(\eta) = \text{ACC}(2)$.

8. Further Comments

The time taken by the routine will depend upon the sparsity of the factorization and the number of iterations required. The number of iterations will be affected by the nature of the factorization supplied by F01MAF. The more incomplete the factorization, the higher the number of iterations required by F04MAF.

When the solution of several systems of equations, all with the same matrix of coefficients, A, is required, then F01MAF need be called only once to factorize A. This is illustrated in the context of an eigenvalue problem in the example program for F02FJF.

9. Example

The example program illustrates the use of F01MAF in conjunction with F04MAF to solve the 16 linear equations $Ax=b$, where

$$A = \begin{pmatrix} 1 & a & & & & & & & & & & & & & & \\ a & 1 & a & & & & & & & & & & & & & \\ & a & 1 & a & & & & & & & & & & & & \\ & & a & 1 & 0 & & & & & & & & & & & \\ a & & & 0 & 1 & a & & & & & & & & & & \\ & a & & & a & 1 & a & & & & & & & & & \\ & & a & & & a & 1 & a & & & & & & & & \\ & & & a & & & a & 1 & 0 & & & & & & & \\ & & & & a & & & 0 & 1 & a & & & & & & \\ & & & & & a & & & a & 1 & a & & & & & \\ & & & & & & a & & & a & 1 & a & & & & \\ & & & & & & & a & & & a & 1 & 0 & & & a \\ & & & & & & & & a & & & 0 & 1 & a & & \end{pmatrix}$$

$$\begin{pmatrix} & a & & a & 1 & a \\ & & a & & a & 1 \\ & & & a & & a \end{pmatrix}$$

where $a = -\frac{1}{4}$.

$$b = \begin{pmatrix} 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ - & - & - & - & - & 0 & 0 & - & - & 0 & 0 \\ 2 & 4 & 4 & 2 & 4 & 4 & 4 & 2 & 4 & 4 & 2 \end{pmatrix}$$

The n by n matrix A arises in the solution of Laplace's equation in a unit-square, using a five-point formula with a 6 by 6 discretisation, with unity on the boundaries.

The drop tolerance, DROPTL, is taken as 0.1 and the density factor, DENSW, is taken as 0.8. The value IFAIL = 111 is used so that advisory and error messages will be printed, but soft failure would occur if IFAIL were returned as non-zero.

A relative accuracy of about 0.0001 is requested in the solution from F04MAF, with a maximum of 50 iterations.

The example program for F02FJF illustrates the use of routines F01MAF and F04MAF in solving an eigenvalue problem.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F04 -- Simultaneous Linear Equations F04MBF
F04MBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F04MBF solves a system of real sparse symmetric linear equations using a Lanczos algorithm.

2. Specification

```

SUBROUTINE F04MBF (N, B, X, APROD, MSOLVE, PRECON, SHIFT,
1              RTOL, ITNLIM, MSGGLVL, ITN, ANORM,
2              ACOND, RNORM, XNORM, WORK, RWORK,
3              LRWORK, IWORK, LIWORK, INFORM, IFAIL)
  INTEGER      N, ITNLIM, MSGGLVL, ITN, LRWORK, IWORK
1              (LIWORK), LIWORK, INFORM, IFAIL
  DOUBLE PRECISION B(N), X(N), SHIFT, RTOL, ANORM, ACOND,
1              RNORM, XNORM, WORK(N,5), RWORK(LRWORK)
  LOGICAL      PRECON
  EXTERNAL     APROD, MSOLVE

```

3. Description

F04MBF solves the system of linear equations

$$(A - (\text{lambda})I)x = b \quad (3.1)$$

where A is an n by n sparse symmetric matrix and (lambda) is a scalar, which is of course zero if the solution of the equations

$$Ax = b$$

is required. It should be noted that neither A nor $(A - (\text{lambda})I)$ need be positive-definite.

(lambda) is supplied as the parameter `SHIFT`, and allows F04MBF to be used for finding eigenvectors of A in methods such as Rayleigh quotient iteration (see for example Lewis [1]), in which case (lambda) will be an approximation to an eigenvalue of A and b an approximation to an eigenvector of A .

The routine also provides an option to allow pre-conditioning and this will often reduce the number of iterations required by F04MBF.

F04MBF is based upon algorithm SYMMLQ (see Paige and Saunders [2]) and solves the equations by an algorithm based upon the

Lanczos process. Details of the method are given in Paige and Saunders [2]. The routine does not require A explicitly, but A is specified via a user-supplied routine `APROD` which, given an n element vector c , must return the vector z given by

$$z = Ac.$$

The pre-conditioning option is based on the following reasoning.
If A can be expressed in the form

$$A=I+B$$

where B is of rank (ρ) , then the Lanczos process converges (in exact arithmetic) in at most (ρ) iterations. If more generally A can be expressed in the form

$$A=M+C$$

where M is symmetric positive-definite and C has rank (ρ) , then

$$\begin{array}{ccccccc} & -(1/2) & & -(1/2) & & -(1/2) & & -(1/2) \\ M & & AM & & =I+M & & CM \end{array}$$

$-(1/2) \quad -(1/2)$
 and $M \quad A_M$ also has rank (ρ) , and the Lanczos process
 $-(1/2) \quad -(1/2)$
 applied to $M \quad A_M$ would again converge in at most (ρ)
 iterations. On a computer, the number of iterations may be
 greater than (ρ) , but the Lanczos process may still be expected
 $-(1/2) \quad -(1/2)$
 to converge rapidly. F04MBF does not require $M \quad A_M$ to
 be formed explicitly, but implicitly solves the equations

$$M^{-(1/2)} (A - (\lambda)I) M^{-(1/2)} y = M^{-(1/2)} b, \quad y = M^{1/2} x \quad (3.2)$$

with the user being required to supply a routine MSOLVE to solve the equations

$$M_Z = c. \quad (3.3)$$

For the pre-conditioning option to be effective, it is desirable that equations (3.3) can be solved efficiently. The example program in Section 9 illustrates the use of this option.

If we let \mathbf{r} denote the residual vector

$$r = b - (A - (\lambda)I)x$$

corresponding to an iterate x , then, when pre-conditioning has not been requested, the iterative procedure is terminated if it is estimated that

$$||r|| \leq \text{tol} \cdot ||A - (\lambda)I|| \cdot ||x||, \quad (3.4)$$

where tol is a user-supplied tolerance, $||r||$ denotes the Euclidean length of the vector r and $||A||$ denotes the Frobenius (Euclidean) norm of the matrix A . When pre-conditioning has been requested, the iterative procedure is terminated if it is estimated that

$$||M^{-(1/2)} r|| \leq \text{tol} \cdot ||M^{-(1/2)} (A - (\lambda)I) M^{-(1/2)} x||. \quad (3.5)$$

Note that

$$M^{-(1/2)} r = (M^{-(1/2)} b) - M^{-(1/2)} (A - (\lambda)I) M^{-(1/2)} (M^{1/2} x)$$

so that $M^{-(1/2)} r$ is the residual vector corresponding to equation (3.2). The routine will also terminate if it is estimated that

$$||A - (\lambda)I|| \cdot ||x|| \geq ||b|| / (\epsilon), \quad (3.6)$$

where (ϵ) is the machine precision, when pre-conditioning has not been requested; or if it is estimated that

$$||M^{-(1/2)} (A - (\lambda)I) M^{-(1/2)} x|| \geq ||M^{-(1/2)} b|| / (\epsilon) \quad (3.7)$$

when pre-conditioning has been requested. If (3.6) is satisfied then x is almost certainly an eigenvector of A corresponding to the eigenvalue (λ) . If (λ) was set to 0 (for the solution of $Ax=b$), then this condition simply means that A is effectively singular.

5. Parameters

- 1: N -- INTEGER Input
On entry: n, the order of the matrix A. Constraint: $N \geq 1$.
- 2: B(N) -- DOUBLE PRECISION array Input
On entry: the right-hand side vector b.
- 3: X(N) -- DOUBLE PRECISION array Output
On exit: the solution vector x.
- 4: APROD -- SUBROUTINE, supplied by the user. External Procedure
APROD must return the vector $y=Ax$ for a given vector x.

Its specification is:

```

SUBROUTINE APROD (IFLAG, N, X, Y, RWORK, LRWORK,
1                IWORK,LIWORK)
  INTEGER          IFLAG, N, LRWORK, LIWORK, IWORK
1                (LIWORK)
  DOUBLE PRECISION X(N), Y(N), RWORK(LRWORK)

```

- 1: IFLAG -- INTEGER Input/Output
On entry: IFLAG is always non-negative. On exit: IFLAG may be used as a flag to indicate a failure in the computation of Ax . If IFLAG is negative on exit from APROD, F04MBF will exit immediately with IFAIL set to IFLAG.
- 2: N -- INTEGER Input
On entry: n, the order of the matrix A.
- 3: X(N) -- DOUBLE PRECISION array Input
On entry: the vector x for which Ax is required.
- 4: Y(N) -- DOUBLE PRECISION array Output
On exit: the vector $y=Ax$.
- 5: RWORK(LRWORK) -- DOUBLE PRECISION array User Workspace
- 6: LRWORK -- INTEGER Input
- 7: IWORK(LIWORK) -- INTEGER array User Workspace

15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1833

8: LIWORK -- INTEGER Input
 APROD is called from F04MBF with the parameters RWORK, LRWORK, IWORK and LIWORK as supplied to F04MBF. The user is free to use the arrays RWORK and IWORK to supply information to APROD and MSOLVE as an alternative to using COMMON.

APROD must be declared as EXTERNAL in the (sub)program from which F04MBF is called. Parameters denoted as Input must not be changed by this procedure.

5: MSOLVE -- SUBROUTINE, supplied by the user.

External Procedure

MSOLVE is only referenced when PRECON is supplied as .TRUE.. When PRECON is supplied as .FALSE., then F04MBF may be called with APROD as the actual argument for MSOLVE. When PRECON is supplied as .TRUE., then MSOLVE must return the solution y of the equations $My=x$ for a given vector x, where M must be symmetric positive-definite.

Its specification is:

```

      SUBROUTINE MSOLVE (IFLAG, N, X, Y, RWORK,
1                      LRWORK, IWORK, LIWORK)
      INTEGER          IFLAG, N, LRWORK, LIWORK, IWORK
1                      (LIWORK)
      DOUBLE PRECISION X(N), Y(N), RWORK(LRWORK)

```

1: IFLAG -- INTEGER Input/Output
 On entry: IFLAG is always non-negative. On exit: IFLAG may be used as a flag to indicate a failure in the solution of $My=x$.

If IFLAG is negative on exit from MSOLVE, F04MBF will exit immediately with IFAIL set to IFLAG.

2: N -- INTEGER Input
 On entry: n, the order of the matrix M.

3: X(N) -- DOUBLE PRECISION array Input
 On entry: the vector x for which the equations $My=x$ are to be solved.

4: Y(N) -- DOUBLE PRECISION array Output
 On exit: the solution to the equations $My=x$.

- 5: RWORK(LRWORK) -- DOUBLE PRECISION array User Workspace
- 6: LRWORK -- INTEGER Input
- 7: IWORK(LIWORK) -- INTEGER array User Workspace
- 8: LIWORK -- INTEGER Input
- MSOLVE is called from F04MBF with the parameters RWORK, LRWORK, IWORK and LIWORK as supplied to F04MBF. The user is free to use the arrays RWORK and IWORK to supply information to APROD and MSOLVE as an alternative to using COMMON.
- MSOLVE must be declared as EXTERNAL in the (sub)program from which F04MBF is called. Parameters denoted as Input must not be changed by this procedure.
- 6: PRECON -- LOGICAL Input
- On entry: PRECON specifies whether or not pre-conditioning is required. If PRECON = .TRUE., then pre-conditioning will be invoked and MSOLVE will be referenced by F04MBF; if PRECON = .FALSE., then MSOLVE is not referenced.
- 7: SHIFT -- DOUBLE PRECISION Input
- On entry: the value of (λ). If the equations $Ax=b$ are to be solved, then SHIFT must be supplied as zero.
- 8: RTOL -- DOUBLE PRECISION Input
- On entry: the tolerance for convergence, tol, of equation (3.4). RTOL should not normally be less than (epsilon), where (epsilon) is the machine precision.
- 9: ITNLIM -- INTEGER Input
- On entry: an upper limit on the number of iterations. If ITNLIM ≤ 0 , then the value N is used in place of ITNLIM.
- 10: MSGLVL -- INTEGER Input
- On entry: the level of printing from F04MBF. If MSGLVL ≤ 0 , then no printing occurs, but otherwise messages will be output on the advisory message channel (see X04ABF). A description of the printed output is given in Section 5.1 below. The level of printing is determined as follows:
- MSGLVL ≤ 0
 No printing.
- MSGLVL = 1
 A brief summary is printed just prior to return from

15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1835

F04MBF.

MSGVLVL ≥ 2

A summary line is printed periodically to monitor the progress of F04MBF, together with a brief summary just prior to return from F04MBF.

- 11: ITN -- INTEGER Output
On exit: the number of iterations performed.

- 12: ANORM -- DOUBLE PRECISION Output
On exit: an estimate of $\|A-(\lambda)I\|$ when PRECON =
 $-(1/2)$ $-(1/2)$
.FALSE., and $\|M$ $(A-(\lambda)I)M$ $\|$ when PRECON =
.TRUE..

- 13: ACOND -- DOUBLE PRECISION Output
On exit: an estimate of the condition number of $(A-(\lambda)I)$ when PRECON = .FALSE., and of
 $-(1/2)$ $-(1/2)$
 M $(A-(\lambda)I)M$ $\|$ when PRECON = .TRUE.. This will
usually be a substantial under-estimate.

- 14: RNORM -- DOUBLE PRECISION Output
On exit: $\|r\|$, where $r=b-(A-(\lambda)I)x$ and x is the
solution returned in X.

- 15: XNORM -- DOUBLE PRECISION Output
On exit: $\|x\|$, where x is the solution returned in X.

- 16: WORK(5*N) -- DOUBLE PRECISION array Workspace

- 17: RWORK(LRWORK) -- DOUBLE PRECISION array User Workspace
RWORK is not used by F04MBF, but is passed directly to
routines APROD and MSOLVE and may be used to pass
information to these routines.

- 18: LRWORK -- INTEGER Input
On entry: the length of the array RWORK as declared in the
(sub)program from which F04MBF is called. Constraint: LRWORK
 ≥ 1 .

- 19: IWORK(LIWORK) -- INTEGER array User Workspace
IWORK is not used by F04MBF, but is passed directly to
routines APROD and MSOLVE and may be used to pass
information to these routines.

20: LIWORK -- INTEGER Input
 On entry: the length of the array IWORK as declared in the
 (sub)program from which F04MBF is called. Constraint: LIWORK
 ≥ 1 .

21: INFORM -- INTEGER Output
 On exit: the reason for termination of F04MBF as follows:
 INFORM = 0
 The right-hand side vector $b=0$ so that the exact
 solution is $x=0$. No iterations are performed in this
 case.

INFORM = 1
 The termination criterion of equation (3.4) has been
 satisfied with tol as the value supplied in RTOL.

INFORM = 2
 The termination criterion of equation (3.4) has been
 satisfied with tol equal to (epsilon), where (epsilon)
 is the machine precision. The value supplied in RTOL
 must have been less than (epsilon) and was too small
 for the machine.

INFORM = 3
 The termination criterion of equation (3.5) has been
 satisfied so that X is almost certainly an eigenvector
 of A corresponding to the eigenvalue SHIFT.
 The values INFORM = 4 and INFORM = 5 correspond to failure
 with IFAIL = 3 or IFAIL = 2 respectively (see Section 6) and
 when IFAIL is negative, INFORM will be set to the same
 negative value.

22: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not
 familiar with this parameter (described in the Essential
 Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
 Section 6).

5.1. Description of the Printed Output

When MSGVLV > 0 , then F04MBF will produce output (except in the
 case where the routine fails with IFAIL = 1) on the advisory
 message channel (see X04ABF).

15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1837

The following notation is used in the output.

Output	Meaning
RBAR	$M^{-(1/2)} (b - (A - (\lambda)I)x) = r$
ABAR	$M^{-(1/2)} (A - (\lambda)I) M^{-(1/2)} = A$
Y	$M^{1/2} x$
R	$b - (A - (\lambda)I)x$
NORM(A)	$\ A\ $

Of course, when pre-conditioning has not been requested then the first three reduce to $(b - (A - (\lambda)I)x)$, $(A - (\lambda)I)$ and x respectively. When MSGVLV ≥ 2 then some initial information is printed and the following notation is used.

Output	Meaning
BETA1	$(b^T M^{-1} b)^{-1/2} = (\beta)$
ALFA1	$(1/(\beta)) (M^{-1/2} b)^T (M^{-1/2} A M^{-1/2}) (M^{-1/2} b)^{-1/2} = (\alpha)$

and a summary line is printed periodically giving the following information:

Output	Meaning
ITN	Iteration number, k .
X1(LQ)	The first element of the vector x_k^L , where x_k^L is the current iterate. See Paige and Saunders [2] for details.

X1(CG) The first element of the vector x_k^C , where x_k^C is the vector that would be obtained by conjugate gradients. See Paige and Saunders [2] for details.

NORM(RBAR) $\|r\|$, where r is as defined above and x is either x_k^L or x_k^C depending upon which is the best current approximation to the solution. (See LQ/CG below).

NORM(T) The value $\|T_k\|$, where T_k is the tridiagonal matrix of the Lanczos process. This increases monotonically and is a lower bound on $\|A\|$.

COND(L) A monotonically increasing lower bound on the condition number of A , $\|A\| \|A\|^{-1}$.

LQ/CG L is printed if x_k^L is the best current approximation to the solution and C is printed otherwise.

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL < 0

A negative value of IFAIL indicates an exit from F04MBF because the user has set IFLAG negative in APR0D or MSOLVE. The value of IFAIL will be the same as the user's setting of IFLAG.

IFAIL = 1

On entry $N < 1$,

or $LRWORK < 1$,

or $LIWORK < 1$.

IFAIL= 2

The pre-conditioning matrix M does not appear to be positive-definite. The user should check that MSOLVE is working correctly.

IFAIL= 3

The limit on the number of iterations has been reached. If IFAIL = 1 on entry then the latest approximation to the solution is returned in X and the values ANORM, ACOND, RNORM and XNORM are also returned.

The value of INFORM contains additional information about the termination of the routine and users must examine INFORM to judge whether the routine has performed successfully for the problem in hand. In particular INFORM = 3 denotes that the matrix $A - (\lambda)I$ is effectively singular: if the purpose of calling F04MBF is to solve a system of equations $Ax=b$, then this condition must be regarded as a failure, but if the purpose is to compute an eigenvector, this result would be very satisfactory.

7. Accuracy

The computed solution x will satisfy the equation

$$r = b - (A - (\lambda)I)x$$

where the value $\|r\|$ is as returned in the parameter RNORM.

8. Further Comments

The time taken by the routine is likely to be principally determined by the time taken in APROD and, when pre-conditioning has been requested, in MSOLVE. Each of these routines is called once every iteration.

The time taken by the remaining operations in F04MBF is approximately proportional to n.

9. Example

To solve the 10 equations $Ax=b$ given by

$$(2 \ 1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 3) \quad (6)$$

$$\begin{aligned}
 & \begin{pmatrix} 1 & 2 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix} & (4) \\
 & \begin{pmatrix} 0 & 1 & 2 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix} & (4) \\
 & \begin{pmatrix} 0 & 0 & 1 & 2 & 1 & 0 & 0 & 0 & 0 & 0 \end{pmatrix} & (4) \\
 & \begin{pmatrix} 0 & 0 & 0 & 1 & 2 & 1 & 0 & 0 & 0 & 0 \end{pmatrix} & (4) \\
 A = & \begin{pmatrix} 0 & 0 & 0 & 0 & 1 & 2 & 1 & 0 & 0 & 0 \end{pmatrix}, & b = (4). \\
 & \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 1 & 2 & 1 & 0 & 0 \end{pmatrix} & (4) \\
 & \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 1 & 2 & 1 & 0 \end{pmatrix} & (4) \\
 & \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 2 & 1 \end{pmatrix} & (4) \\
 & \begin{pmatrix} 3 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 2 \end{pmatrix} & (6)
 \end{aligned}$$

The tridiagonal part of A is positive-definite and such tridiagonal equations can be solved efficiently by F04FAF. The form of A suggests that this tridiagonal part is a good candidate for the pre-conditioning matrix M and so we illustrate the use of F04MBF by pre-conditioning with the 10 by 10 matrix

$$\begin{aligned}
 & \begin{pmatrix} 2 & 1 & 0 & \dots & 0 \end{pmatrix} \\
 & \begin{pmatrix} 1 & 2 & 1 & \dots & 0 \end{pmatrix} \\
 & \begin{pmatrix} 0 & 1 & 2 & \dots & 0 \end{pmatrix} \\
 M = & \begin{pmatrix} . & . & . & . & . \end{pmatrix} \\
 & \begin{pmatrix} . & . & . & . & . \end{pmatrix} \\
 & \begin{pmatrix} . & . & . & . & . \end{pmatrix} \\
 & \begin{pmatrix} 0 & 0 & 0 & \dots & 2 \end{pmatrix}
 \end{aligned}$$

Since A-M has only 2 non-zero elements and is obviously of rank 2, we can expect F04MBF to converge very quickly in this example. Of course, in practical problems we shall not usually be able to make such a good choice of M.

-5

The example sets the tolerance RTOL = 10 .

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F04 -- Simultaneous Linear Equations

F04MCF

F04MCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F04MCF computes the approximate solution of a system of real linear equations with multiple right-hand sides, $AX=B$, where A is a symmetric positive-definite variable-bandwidth matrix, which has previously been factorized by F01MCF. Related systems may also be solved.

2. Specification

```

SUBROUTINE F04MCF (N, AL, LAL, D, NROW, IR, B, NRB,
1                ISELECT, X, NRX, IFAIL)
INTEGER          N, LAL, NROW(N), IR, NRB, ISELECT, NRX,
1                IFAIL
DOUBLE PRECISION AL(LAL), D(N), B(NRB,IR), X(NRX,IR)

```

3. Description

The normal use of this routine is the solution of the systems $AX=B$, following a call of F01MCF to determine the Cholesky

factorization $A=LDL^T$ of the symmetric positive-definite variable-bandwidth matrix A .

However, the routine may be used to solve any one of the following systems of linear algebraic equations:

- (1) $LDL^T X = B$ (usual system),
- (2) $LDX = B$ (lower triangular system),
- (3) $DL^T X = B$ (upper triangular system),
- (4) $LL^T X = B$
- (5) $LX = B$ (unit lower triangular system),
- (6) $L^T X = B$ (unit upper triangular system).

L denotes a unit lower triangular variable-bandwidth matrix of order n , D a diagonal matrix of order n , and B a set of right-

hand sides.

The matrix L is represented by the elements lying within its envelope i.e., between the first non-zero of each row and the diagonal (see Section 9 for an example). The width $NROW(i)$ of the i th row is the number of elements between the first non-zero element and the element on the diagonal inclusive.

4. References

- [1] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

- 1: N -- INTEGER Input
On entry: n , the order of the matrix L . Constraint: $N \geq 1$.
- 2: $AL(LAL)$ -- DOUBLE PRECISION array Input
On entry: the elements within the envelope of the lower triangular matrix L , taken in row by row order, as returned by F01MCF. The unit diagonal elements of L must be stored explicitly.
- 3: LAL -- INTEGER Input
On entry:
the dimension of the array AL as declared in the (sub)program from which F04MCF is called.
Constraint: $LAL \geq NROW(1) + NROW(2) + \dots + NROW(n)$.
- 4: $D(N)$ -- DOUBLE PRECISION array Input
On entry: the diagonal elements of the diagonal matrix D . D is not referenced if $ISELCT \geq 4$.
- 5: $NROW(N)$ -- INTEGER array Input
On entry: $NROW(i)$ must contain the width of row i of L , i.e., the number of elements between the first (leftmost) non-zero element and the element on the diagonal, inclusive.
Constraint: $1 \leq NROW(i) \leq i$.
- 6: IR -- INTEGER Input
On entry: r , the number of right-hand sides. Constraint: $IR \geq 1$.
- 7: $B(NRB, IR)$ -- DOUBLE PRECISION array Input
On entry: the n by r right-hand side matrix B . See also

15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1843

Section 8.

8: NRB -- INTEGER Input
 On entry:
 the first dimension of the array B as declared in the
 (sub)program from which F04MCF is called.
 Constraint: NRB \geq N.

9: ISELCT -- INTEGER Input
 On entry: ISELCT must specify the type of system to be
 solved, as follows:

T

ISELCT = 1: solve LDL X = B,

ISELCT = 2: solve LDX = B,

T

ISELCT = 3: solve DL X = B,

T

ISELCT = 4: solve LL X = B,

ISELCT = 5: solve LX = B,

T

ISELCT = 6: solve L X = B.

10: X(NRX,IR) -- DOUBLE PRECISION array Output
 On exit: the n by r solution matrix X. See also Section 8.

11: NRX -- INTEGER Input
 On entry:
 the first dimension of the array X as declared in the
 (sub)program from which F04MCF is called.
 Constraint: NRX \geq N.

12: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not
 familiar with this parameter (described in the Essential
 Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
 Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

On entry $N < 1$,

or for some i , $NROW(i) < 1$ or $NROW(i) > i$,

or $LAL < NROW(1) + NROW(2) + \dots + NROW(N)$.

IFAIL= 2

On entry $IR < 1$,

or $NRB < N$,

or $NRX < N$.

IFAIL= 3

On entry $ISELCT < 1$,

or $ISELCT > 6$.

IFAIL= 4

The diagonal matrix D is singular, i.e., at least one of the elements of D is zero. This can only occur if $ISELCT \leq 3$.

IFAIL= 5

At least one of the diagonal elements of L is not equal to unity.

7. Accuracy

The usual backward error analysis of the solution of triangular system applies: each computed solution vector is exact for slightly perturbed matrices L and D , as appropriate (cf. Wilkinson and Reinsch [1] pp 25--27, 54--55).

8. Further Comments

The time taken by the routine is approximately proportional to pr , where

$$p = NROW(1) + NROW(2) + \dots + NROW(n).$$

Unless otherwise stated in the Users' Note for your

15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1845

implementation, the routine may be called with the same actual array supplied for the parameters B and X, in which case the solution matrix will overwrite the right-hand side matrix. However this is not standard Fortran 77 and may not work in all implementations.

9. Example

To solve the system of equations $AX=B$, where

```
(1  2  0  0  5  0)
(2  5  3  0 14  0)
(0  3 13  0 18  0)
A=(0  0  0 16  8 24)
(5 14 18  8 55 17)
(0  0  0 24 17 77)
```

and

```
( 6 -10)
(15 -21)
(11  -3)
B=( 0  24)
(51 -39)
(46  67)
```

Here A is symmetric and positive-definite and must first be factorized by F01MCF.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F04 -- Simultaneous Linear Equations F04QAF
F04QAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F04QAF solves sparse unsymmetric equations, sparse linear least-

squares problems and sparse damped linear least-squares problems, using a Lanczos algorithm.

2. Specification

```

SUBROUTINE F04QAF (M, N, B, X, SE, APROD, DAMP, ATOL,
1                BTOL, CONCLIM, ITNLIM, MSGVLV, ITN,
2                ANORM, ACOND, RNORM, ARNORM, XNORM,
3                WORK, RWORK, LRWORK, IWORK, LIWORK,
4                INFORM, IFAIL)
  INTEGER          M, N, ITNLIM, MSGVLV, ITN, LRWORK, IWORK
1                (LIWORK), LIWORK, INFORM, IFAIL
  DOUBLE PRECISION B(M), X(N), SE(N), DAMP, ATOL, BTOL,
1                CONCLIM, ANORM, ACOND, RNORM, ARNORM,
2                XNORM, WORK(N,2), RWORK(LRWORK)
  EXTERNAL          APROD

```

3. Description

F04QAF can be used to solve a system of linear equations

$$Ax=b \quad (3.1)$$

where A is an n by n sparse unsymmetric matrix, or can be used to solve linear least-squares problems, so that F04QAF minimizes the value (rho) given by

$$(\text{rho})=||r||, \quad r=b-Ax \quad (3.2)$$

where A is an m by n sparse matrix and $||r||$ denotes the

Euclidean length of r so that $||r|| = \sqrt{r^T r}$. A damping parameter, (lambda), may be included in the least-squares problem in which case F04QAF minimizes the value (rho) given by

$$(\text{rho}) = \sqrt{r^T r} + (\text{lambda}) \sqrt{x^T x} \quad (3.3)$$

(lambda) is supplied as the parameter DAMP and should of course be zero if the solution to problems (3.1) or (3.2) is required. Minimizing (rho) in (3.3) is often called ridge regression.

F04QAF is based upon algorithm LSQR (see Paige and Saunders [1] and [2]) and solves the problems by an algorithm based upon the Lanczos process. Details of the method are given in [1]. The routine does not require A explicitly, but A is specified via a

15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1847

user-supplied routine APR0D which must perform the operations $(y + Ax)^T$ and $(x + A^T y)$ for a given n element vector x and m element vector y . A parameter to APR0D specifies which of the two operations is required on a given entry.

The routine also returns estimates of the standard errors of the sample regression coefficients (x_i) , for $i=1,2,\dots,n$ given by the diagonal elements of the estimated variance-covariance matrix V . When problem (3.2) is being solved and A is of full rank, then V is given by

$$V = s^2 (A^T A)^{-1}, \quad s^2 = (\text{rho}) / (m-n), \quad m > n$$

and when problem (3.3) is being solved then V is given by

$$V = s^2 (A^T A + (\text{lambda}) I)^{-1}, \quad s^2 = (\text{rho}) / m, \quad (\text{lambda}) \neq 0.$$

Let A denote the matrix

$$A = \begin{pmatrix} A \\ (\text{lambda})I \end{pmatrix}, \quad (\text{lambda}) \neq 0, \quad (3.4)$$

let r denote the residual vector

$$r = \begin{pmatrix} r \\ (\text{lambda})I \end{pmatrix}, \quad r = (0) - Ax, \quad (\text{lambda}) \neq 0 \quad (3.5)$$

corresponding to an iterate x , so that $(\text{rho}) = ||r||$ is the function being minimized, and let $||A||$ denote the Frobenius (Euclidean) norm of A . Then the routine accepts x as a solution if it is estimated that one of the following two conditions is satisfied:

$$(\text{rho}) \leq \text{tol} ||A|| ||x|| + \text{tol} ||b|| \quad (3.6)$$

$$\|A^{-T} r\| \leq \text{tol}_1 \|A\| \text{tol}_2 \quad (3.7)$$

where tol_1 and tol_2 are user-supplied tolerances which estimate the relative errors in A and b respectively. Condition (3.6) is appropriate for compatible problems where, in theory, we expect the residual to be zero and will be satisfied by an acceptable solution x to a compatible problem. Condition (3.7) is appropriate for incompatible systems where we do not expect the residual to be zero and is based upon the observation that, in theory,

$$A^{-T} r = 0$$

when x is a solution to the least-squares problem, and so (3.7) will be satisfied by an acceptable solution x to a linear least-squares problem.

The routine also includes a test to prevent convergence to solutions, x , with unacceptably large elements. This can happen if A is nearly singular or is nearly rank deficient. If we let

the singular values of A be

$$(\sigma_1) \geq (\sigma_2) \geq \dots \geq (\sigma_n) \geq 0$$

then the condition number of A is defined as

$$\text{cond}(A) = (\sigma_1) / (\sigma_k)$$

where (σ_k) is the smallest non-zero singular value of A and

hence k is the rank of A . When $k < n$, then A is rank deficient, the least-squares solution is not unique and F04QAF will normally

converge to the minimal length solution. In practice A will not have exactly zero singular values, but may instead have small singular values that we wish to regard as zero.

The routine provides for this possibility by terminating if

$$\text{cond}(A) \geq c_{\text{lim}} \quad (3.8)$$

where c_{lim} is a user-supplied limit on the condition number of A .

For problem (3.1) termination with this condition indicates that A is nearly singular and for problem (3.2) indicates that A is nearly rank deficient and so has near linear dependencies in its

columns. In this case inspection of $\|r\|$, $\|A^T r\|$ and $\|x\|$, which are all returned by the routine, will indicate whether or not an acceptable solution has been found. Condition (3.8), perhaps in conjunction with $(\lambda) \neq 0$, can be used to try and 'regularise' least-squares solutions. A full discussion of the stopping criteria is given in Section 6 of reference Paige and Saunders [1].

Introduction of a non-zero damping parameter (λ) tends to reduce the size of the computed solution and to make its components less sensitive to changes in the data, and F04QAF is applicable when a value of (λ) is known a priori. To have an

effect, (λ) should normally be at least $\sqrt{(\epsilon)} \|A\|$ where (ϵ) is the machine precision. For further discussion see Paige and Saunders [2] and the references given there.

Whenever possible the matrix A should be scaled so that the relative errors in the elements of A are all of comparable size. Such a scaling helps to prevent the least-squares problem from

being unnecessarily sensitive to data errors and will normally reduce the number of iterations required. At the very least, in the absence of better information, the columns of A should be scaled to have roughly equal column length.

5. Parameters

- 1: M -- INTEGER Input
 On entry: m, the number of rows of the matrix A.
 Constraint: M >= 1.
- 2: N -- INTEGER Input
 On entry: n, the number of columns of the matrix A.
 Constraint: N >= 1.
- 3: B(M) -- DOUBLE PRECISION array Input/Output
 On entry: the right-hand side vector b. On exit: the array is overwritten.
- 4: X(N) -- DOUBLE PRECISION array Output
 On exit: the solution vector x.
- 5: SE(N) -- DOUBLE PRECISION array Output
 On exit: the estimates of the standard errors of the components of x. Thus SE(i) contains an estimate of the element v_{ii} of the estimated variance-covariance matrix V.
 The estimates returned in SE will be the lower bounds on the actual estimated standard errors, but will usually have at least one correct figure.
- 6: APROD -- SUBROUTINE, supplied by the user. External Procedure

T

 APROD must perform the operations $y:=y+Ax$ and $x:=x+A^T y$ for given vectors x and y.

Its specification is:

```

SUBROUTINE APROD (MODE, M, N, X, Y, RWORK,
1                LRWORK, IWORK, LIWORK)
INTEGER          MODE, M, N, LRWORK, LIWORK,
1                IWORK(LIWORK)
DOUBLE PRECISION X(N), Y(M), RWORK(LRWORK)

```

- 1: MODE -- INTEGER Input/Output
 On entry: MODE specifies which operation is to be performed:
 If MODE = 1, then APROD must compute $y+Ax$.

T

If MODE = 2, then APROD must compute $x+A y$.
 On exit: MODE may be used as a flag to indicate a
 failure in the computation of $y+Ax$ or $x+A y$. If MODE is
 negative on exit from APROD, FO4QAF will exit
 immediately with IFAIL set to MODE.

- 2: M -- INTEGER Input
 On entry: m, the number of rows of A.

- 3: N -- INTEGER Input
 On entry: n, the number of columns of A.

- 4: X(N) -- DOUBLE PRECISION array Input/Output
 On entry: the vector x. On exit: if MODE = 1, X must be unchanged;

T

If MODE = 2, X must contain $x+A y$.

- 5: Y(M) -- DOUBLE PRECISION array Input/Output
 On entry: the vector y. On exit: if MODE = 1, Y must contain $y+Ax$;

If MODE = 2, Y must be unchanged.

- 6: RWORK(LRWORK) -- DOUBLE PRECISION array User Workspace

- 7: LRWORK -- INTEGER Input

- 8: IWORK(LIWORK) -- INTEGER array User Workspace

9: LIWORK -- INTEGER Input
 APROD is called from F04QAF with the parameters RWORK, LRWORK, IWORK and LIWORK as supplied to F04QAF. The user is free to use the arrays RWORK and IWORK to supply information to APROD as an alternative to using COMMON.

APROD must be declared as EXTERNAL in the (sub)program from which F04QAF is called. Parameters denoted as Input must not be changed by this procedure.

7: DAMP -- DOUBLE PRECISION Input
 On entry: the value (lambda). If either problem (3.1) or problem (3.2) is to be solved, then DAMP must be supplied as zero.

8: ATOL -- DOUBLE PRECISION Input
 On entry: the tolerance, tol_1 , of the convergence criteria (3.6) and (3.7); it should be an estimate of the largest relative error in the elements of A. For example, if the elements of A are correct to about 4 significant figures, -4 , then ATOL should be set to about $5 \cdot 10^{-4}$. If ATOL is supplied as less than (epsilon), where (epsilon) is the machine precision, then the value (epsilon) is used in place of ATOL.

9: BTOL -- DOUBLE PRECISION Input
 On entry: the tolerance, tol_2 , of the convergence criterion (3.6); it should be an estimate of the largest relative error in the elements of B. For example, if the elements of B are correct to about 4 significant figures, then BTOL -4 should be set to about $5 \cdot 10^{-4}$. If BTOL is supplied as less than (epsilon), where (epsilon) is the machine precision, then the value (epsilon) is used in place of BTOL.

10: CONLIM -- DOUBLE PRECISION Input
 On entry: the value c_{lim} of equation (3.8); it should be an upper limit on the condition number of A. CONLIM should not normally be chosen much larger than $1.0/\text{ATOL}$. If CONLIM is

15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1853

supplied as zero then the value $1.0/(\text{epsilon})$, where (epsilon) is the machine precision, is used in place of CONLIM.

11: ITNLIM -- INTEGER Input
On entry: an upper limit on the number of iterations. If $\text{ITNLIM} \leq 0$, then the value N is used in place of ITNLIM, but for ill-conditioned problems a higher value of ITNLIM is likely to be necessary.

12: MSGVLV -- INTEGER Input
On entry: the level of printing from F04QAF. If $\text{MSGVLV} \leq 0$, then no printing occurs, but otherwise messages will be output on the advisory message channel (see X04ABF). A description of the printed output is given in Section 5.2 below. The level of printing is determined as follows:

$\text{MSGVLV} \leq 0$

No printing.

$\text{MSGVLV} = 1$

A brief summary is printed just prior to return from F04QAF.

$\text{MSGVLV} \geq 2$

A summary line is printed periodically to monitor the progress of F04QAF, together with a brief summary just prior to return from F04QAF.

13: ITN -- INTEGER Output
On exit: the number of iterations performed.

14: ANORM -- DOUBLE PRECISION Output

On exit: an estimate of $\|A\|$ for the matrix A of equation (3.4).

15: ACOND -- DOUBLE PRECISION Output

On exit: an estimate of $\text{cond}(A)$ which is a lower bound.

16: RNORM -- DOUBLE PRECISION Output

On exit: an estimate of $\|r\|$ for the residual, r , of

equation (3.5) corresponding to the solution x returned in

X. Note that $||r||$ is the function being minimized.

- 17: ARNORM -- DOUBLE PRECISION Output
T
 On exit: an estimate of the $||A r||$ corresponding to the solution x returned in X.
- 18: XNORM -- DOUBLE PRECISION Output
 On exit: an estimate of $||x||$ for the solution x returned in X.
- 19: WORK(2*N) -- DOUBLE PRECISION array Workspace
- 20: RWORK(LRWORK) -- DOUBLE PRECISION array User Workspace
 RWORK is not used by F04QAF, but is passed directly to routine APRD and may be used to pass information to that routine.
- 21: LRWORK -- INTEGER Input
 On entry: the length of the array RWORK as declared in the (sub)program from which F04QAF is called. Constraint: LRWORK ≥ 1 .
- 22: IWORK(LIWORK) -- INTEGER array User Workspace
 IWORK is not used by F04QAF, but is passed directly to routine APRD and may be used to pass information to that routine.
- 23: LIWORK -- INTEGER Input
 On entry: the length of the array IWORK as declared in the (sub)program from which F04QAF is called. Constraint: LIWORK ≥ 1 .
- 24: INFORM -- INTEGER Output
 On exit: the reason for termination of F04QAF as follows:
 INFORM = 0
 The exact solution is $x=0$. No iterations are performed in this case.
 INFORM = 1
 The termination criterion of equation (3.6) has been satisfied with tol_1 and tol_2 as the values supplied in

1 2

15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1855

ATOL and BTOL respectively.

INFORM = 2

The termination criterion of equation (3.7) has been satisfied with tol_1 as the value supplied in ATOL.

1

INFORM = 3

The termination criterion of equation (3.6) has been satisfied with tol_1 and/or tol_2 as the value (epsilon)

1

2

, where (epsilon) is the machine precision. One or both of the values supplied in ATOL and BTOL must have been less than (epsilon) and was too small for this machine.

INFORM = 4

The termination criterion of equation (3.7) has been satisfied with tol_1 as the value (epsilon), where

1

(epsilon) is the machine precision. The value supplied in ATOL must have been less than (epsilon) and was too small for this machine.

The values INFORM = 5, INFORM = 6 and INFORM = 7 correspond to failure with IFAIL = 2, IFAIL = 3 and IFAIL = 4 respectively (see Section 6) and when IFAIL is negative INFORM will be set to the same negative value.

25: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

5.1. Description of the printed output

When MSGVLV > 0, then F04QAF will produce output (except in the case where the routine fails with IFAIL = 1) on the advisory message channel (see X04ABF).

When MSGVLV >= 2 then a summary line is printed periodically giving the following information:

Output	Meaning
--------	---------

ITN	Iteration number, k .
X(1)	The first element of the current iterate x_k .
FUNCTION	The current value of the function, (ρ) , being minimized.
COMPAT	An estimate of $\ r_k\ /\ b\ $, where r_k is the residual corresponding to x_k . This value should converge to zero (in theory) if and only if the problem is compatible. COMPAT decreases monotonically.
INCOMPAT	An estimate of $\ A^T r_k\ /(\ A\ \ r_k\)$ which should converge to zero if and only if at the solution (ρ) is non-zero. INCOMPAT is not usually monotonic.
NRM(ABAR)	A monotonically increasing estimate of $\ A\ $.
COND(ABAR)	A monotonically increasing estimate of the condition number $\text{cond}(A)$.

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL < 0

A negative value of IFAIL indicates an exit from F04QAF because the user has set MODE negative in APRD. The value of IFAIL will be the same as the user's setting of MODE.

IFAIL = 1

On entry $M < 1$,

15.5. PACKAGE NAGF04 NAGLINEAREQUATIONSOLVINGPACKAGE1857

or $N < 1$,
or $LRWORK < 1$,
or $LIWORK < 1$.

IFAIL= 2

The condition of equation (3.8) has been satisfied for the value of c supplied in CONLIM. If this failure is
lim
unexpected the user should check that APROD is working correctly. Although conditions (3.6) or (3.7) have not been satisfied, the values returned in RNORM, ARNORM and XNORM may nevertheless indicate that an acceptable solution has been reached.

IFAIL= 3

The conditions of equation (3.8) has been satisfied for the value $c = 1.0/(\text{epsilon})$, where (epsilon) is the machine
lim

precision. The matrix A is nearly singular or rank deficient and the problem is too ill-conditioned for this machine. If this failure is unexpected, the user should check that APROD is working correctly.

IFAIL= 4

The limit on the number of iterations has been reached. The number of iterations required by F04QAF and the condition of

the matrix A can depend strongly on the scaling of the problem. Poor scaling of the rows and columns of A should be avoided whenever possible.

7. Accuracy

When the problem is compatible, the computed solution x will satisfy the equation

$$r=b-Ax,$$

where an estimate of $||r||$ is returned in the parameter RNORM. When the problem is incompatible, the computed solution x will

satisfy the equation

$$\begin{matrix} T \\ A \end{matrix} r = e,$$

where an estimate of $\|e\|$ is returned in the parameter ARNORM. See also Section 6.2 of Paige and Saunders [1].

8. Further Comments

The time taken by the routine is likely to be principally determined by the time taken in APROD, which is called twice on each iteration, once with MODE = 1 and once with MODE = 2. The time taken per iteration by the remaining operations in F04QAF is approximately proportional to $\max(m, n)$.

The Lanczos process will usually converge more quickly if A is pre-conditioned by a non-singular matrix M that approximates A in some sense and is also chosen so that equations of the form $My=c$ can efficiently be solved for y. Some discussion of pre-conditioning in the context of symmetric matrices is given in Section 3 of the document for F04MBF. In the context of F04QAF, problem (3.1) is equivalent to

$$\begin{matrix} -1 \\ (AM) \end{matrix} y = b, \quad Mx = y$$

and problem (3.2) is equivalent to minimizing

$$(rho) = \|r\|, \quad r = b - \begin{matrix} -1 \\ (AM) \end{matrix} y, \quad Mx = y.$$

Note that the normal matrix $\begin{matrix} -1 & T \\ (AM) \end{matrix} \begin{matrix} -1 & -T & T & -1 \\ (AM) \end{matrix} = M^T (A A) M$ so that the pre-conditioning $\begin{matrix} -1 \\ AM \end{matrix}$ is equivalent to the pre-conditioning $\begin{matrix} -T & T & -1 \\ M \end{matrix} \begin{matrix} -T & T & -1 \\ (A A) M \end{matrix}$ of the normal matrix $A A$.

Pre-conditioning can be incorporated into F04QAF simply by coding

the routine APROD to compute $y + \begin{matrix} -1 \\ AM \end{matrix} x$ and $x + \begin{matrix} -T & T \\ M \end{matrix} A y$ in place of $y + Ax$ and $x + A y$ respectively, and then solving the equations $Mx = y$ for x on return from F04QAF. $y + \begin{matrix} -1 \\ AM \end{matrix} x$ should be computed by

solving $Mz=x$ for z and then computing $y+Az$, and $x+M^T A^T y$ should
be computed by solving $M^T z=A^T y$ for z and then forming $x+z$.

9. Example

To solve the linear least-squares problem

$$\text{minimize } (\rho)=||r||, \quad r=b-Ax$$

where A is the 13 by 12 matrix and b is the 13 element vector
given by

$$A=\begin{pmatrix} 1 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & -1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ -1 & 0 & -1 & 4 & -1 & 0 & 0 & -1 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & -1 & 4 & -1 & 0 & 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & -1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 & 0 & -1 & 4 & -1 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 & -1 & 0 & 0 & -1 & 4 & -1 & 0 & -1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 & 1 \\ 1 & 1 & 1 & 0 & 0 & 1 & 1 & 0 & 0 & 1 & 1 & 1 \end{pmatrix},$$

$$b=\begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \\ 1 \\ 2 \\ 0 \\ 1 \\ 1 \\ 0 \\ 0 \\ 0 \\ -3 \\ -h \end{pmatrix}$$

with $h=0.1$.

Such a problem can arise by considering the Neumann problem on a

rectangle

$$\begin{array}{c}
 (\Delta)u \\
 \text{-----} = 0 \\
 (\Delta)n
 \end{array}
 \qquad
 \begin{array}{c}
 (\Delta)u \\
 \text{-----} = 0 \\
 (\Delta)n
 \end{array}
 \qquad
 \begin{array}{c}
 (\Delta)u \\
 \text{-----} = 0 \\
 (\Delta)n
 \end{array}
 \qquad
 \begin{array}{c}
 / \\
 |u=1 \\
 / \\
 c
 \end{array}$$

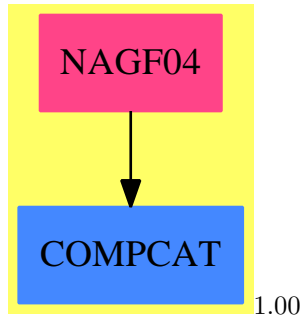

where C is the boundary of the rectangle, and discretising as illustrated below with the square mesh

Please see figure in printed Reference Manual

The 12 by 12 symmetric part of A represents the difference equations and the final row comes from the normalising condition. The example program has $g(x,y)=1$ at all the internal mesh points, but apart from this is written in a general manner so that the number of rows (NROWS) and columns (NCOLS) in the grid can readily be altered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

(package NAGF04 NagLinearEquationSolvingPackage)≡
)abbrev package NAGF04 NagLinearEquationSolvingPackage
++ Author: Godfrey Nolan and Mike Dewar
++ Date Created: Jan 1994
++ Date Last Updated: Thu May 12 17:45:31 1994
++ Description:
++ This package uses the NAG Library to solve the matrix equation
++ \axiom{AX=B}, where \axiom{B}
++ may be a single vector or a matrix of multiple right-hand sides.
++ The matrix \axiom{A} may be real, complex, symmetric, Hermitian positive-
++ definite, or sparse. It may also be rectangular, in which case a
++ least-squares solution is obtained.
++ See \downlink{Manual Page}{manpageXXf04}.

D01 -- Quadrature

Introduction -- D01

Chapter D01
Quadrature

1. Scope of the Chapter

This chapter provides routines for the numerical evaluation of definite integrals in one or more dimensions and for evaluating weights and abscissae of integration rules.

2. Background to the Problems

The routines in this chapter are designed to estimate:

- (a) the value of a one-dimensional definite integral of the form:

$$\int_a^b f(x) dx \quad (1)$$

where $f(x)$ is defined by the user, either at a set of points $(x_i, f(x_i))$, for $i=1,2,\dots,n$ where $a=x_1 < x_2 < \dots < x_n = b$, or in the form of a function; and the limits of integration a, b may be finite or infinite.

Some methods are specially designed for integrands of the form

$$f(x) = w(x)g(x) \quad (2)$$

which contain a factor $w(x)$, called the weight-function, of a specific form. These methods take full account of any peculiar behaviour attributable to the $w(x)$ factor.

- (b) the value of a multi-dimensional definite integral of the form:

$$\int_R \int_{x_1} \int_{x_2} \dots \int_{x_n} f(x_1, x_2, \dots, x_n) dx_1 \dots dx_n \quad (3)$$

where $f(x_1, x_2, \dots, x_n)$ is a function defined by the user and R is some region of n -dimensional space.

The simplest form of R is the n -rectangle defined by:

$$a_i \leq x_i \leq b_i, \quad i=1, 2, \dots, n \quad (4)$$

where a_i and b_i are constants. When a_i and b_i are functions of x_j ($j < i$), the region can easily be transformed to the rectangular form (see Davis and Rabinowitz [1] page 266). Some of the methods described incorporate the transformation procedure.

2.1. One-dimensional Integrals

To estimate the value of a one-dimensional integral, a quadrature rule uses an approximation in the form of a weighted sum of integrand values, i.e.,

$$\int_a^b f(x) dx \approx \sum_{i=1}^N w_i f(x_i). \quad (5)$$

The points x_i within the interval $[a, b]$ are known as the abscissae, and the w_i are known as the weights.

More generally, if the integrand has the form (2), the corresponding formula is

$$\int_a^b w(x)g(x)dx \approx \sum_{i=1}^N w_i g(x_i). \quad (6)$$

If the integrand is known only at a fixed set of points, these points must be used as the abscissae, and the weighted sum is

calculated using finite-difference methods. However, if the functional form of the integrand is known, so that its value at any abscissa is easily obtained, then a wide variety of quadrature rules are available, each characterised by its choice of abscissae and the corresponding weights.

The appropriate rule to use will depend on the interval $[a,b]$ - whether finite or otherwise - and on the form of any $w(x)$ factor in the integrand. A suitable value of N depends on the general behaviour of $f(x)$; or of $g(x)$, if there is a $w(x)$ factor present.

Among possible rules, we mention particularly the Gaussian formulae, which employ a distribution of abscissae which is optimal for $f(x)$ or $g(x)$ of polynomial form.

The choice of basic rules constitutes one of the principles on which methods for one-dimensional integrals may be classified. The other major basis of classification is the implementation strategy, of which some types are now presented.

(a) Single rule evaluation procedures

A fixed number of abscissae, N , is used. This number and the particular rule chosen uniquely determine the weights and abscissae. No estimate is made of the accuracy of the result.

(b) Automatic procedures

The number of abscissae, N , within $[a,b]$ is gradually increased until consistency is achieved to within a level of accuracy (absolute or relative) requested by the user. There are essentially two ways of doing this; hybrid forms of these two methods are also possible:

(i) whole interval procedures (non-adaptive)

A series of rules using increasing values of N are successively applied over the whole interval $[a,b]$. It is clearly more economical if abscissae already used for a lower value of N can be used again as part of a higher-order formula. This principle is known as optimal extension. There is no overlap between the abscissae used in Gaussian formulae of different orders. However, the Kronrod formulae are designed to give an optimal $(2N+1)$ -point formula by adding $(N+1)$ points to an N -point Gauss formula. Further

extensions have been developed by Patterson.

(ii) adaptive procedures

The interval $[a,b]$ is repeatedly divided into a number of sub-intervals, and integration rules are applied separately to each sub-interval. Typically, the subdivision process will be carried further in the neighbourhood of a sharp peak in the integrand, than where the curve is smooth. Thus, the distribution of abscissae is adapted to the shape of the integrand.

Subdivision raises the problem of what constitutes an acceptable accuracy in each sub-interval. The usual global acceptability criterion demands that the sum of the absolute values of the error estimates in the sub-intervals should meet the conditions required of the error over the whole interval. Automatic extrapolation over several levels of subdivision may eliminate the effects of some types of singularities.

An ideal general-purpose method would be an automatic method which could be used for a wide variety of integrands, was efficient (i.e., required the use of as few abscissae as possible), and was reliable (i.e., always gave results within the requested accuracy). Complete reliability is unobtainable, and generally higher reliability is obtained at the expense of efficiency, and vice versa. It must therefore be emphasised that the automatic routines in this chapter cannot be assumed to be 100% reliable. In general, however, the reliability is very high.

2.2. Multi-dimensional Integrals

A distinction must be made between cases of moderately low dimensionality (say, up to 4 or 5 dimensions), and those of higher dimensionality. Where the number of dimensions is limited, a one-dimensional method may be applied to each dimension, according to some suitable strategy, and high accuracy may be obtainable (using product rules). However, the number of integrand evaluations rises very rapidly with the number of dimensions, so that the accuracy obtainable with an acceptable amount of computational labour is limited; for example a product

9

of 3-point rules in 20 dimensions would require more than 10 integrand evaluations. Special techniques such as the Monte Carlo

methods can be used to deal with high dimensions.

(a) Products of one-dimensional rules

Using a two-dimensional integral as an example, we have

$$\begin{array}{c} b \quad b \\ 1 \quad 2 \\ / \quad / \\ | \quad | \quad f(x,y)dydx \sim \\ / \quad / \\ a \quad a \\ 1 \quad 2 \end{array} = \begin{array}{c} N \\ -- \\ i \\ i=1 \end{array} \begin{array}{c} [\quad b \quad] \\ [\quad 2 \quad] \\ [\quad / \quad] \\ [\quad | \quad f(x,y)dy \quad] \\ [\quad / \quad] \\ [\quad a \quad] \\ [\quad 2 \quad] \end{array} \quad (7)$$

$$\begin{array}{c} b \quad b \\ 1 \quad 2 \\ / \quad / \\ | \quad | \quad f(x,y)dydx \sim \\ / \quad / \\ a \quad a \\ 1 \quad 2 \end{array} = \begin{array}{c} N \quad N \\ -- \quad -- \\ i \quad j \\ i=1 \quad j=1 \end{array} \begin{array}{c} > > \\ > > \\ > > \\ > > \\ > > \\ > > \\ > > \end{array} \begin{array}{c} w \quad v \quad f(x,y) \\ i \quad j \quad i \quad j \end{array} \quad (8)$$

where (w_i, x_i) and (v_j, y_j) are the weights and abscissae of the rules used in the respective dimensions.

A different one-dimensional rule may be used for each dimension, as appropriate to the range and any weight function present, and a different strategy may be used, as appropriate to the integrand behaviour as a function of each independent variable.

For a rule-evaluation strategy in all dimensions, the formula (8) is applied in a straightforward manner. For automatic strategies (i.e., attempting to attain a requested accuracy), there is a problem in deciding what accuracy must be requested in the inner integral(s). Reference to formula (7) shows that the presence of a limited but random error in the y-integration for different values of x_i can produce a 'jagged' function of x , which

may be difficult to integrate to the desired accuracy and for this reason products of automatic one-dimensional routines should be used with caution (see also Lyness [3]).

(b) Monte Carlo methods

These are based on estimating the mean value of the

integrand sampled at points chosen from an appropriate statistical distribution function. Usually a variance reducing procedure is incorporated to combat the fundamentally slow rate of convergence of the rudimentary form of the technique. These methods can be effective by comparison with alternative methods when the integrand contains singularities or is erratic in some way, but they are of quite limited accuracy.

(c) Number theoretic methods

These are based on the work of Korobov and Conroy and operate by exploiting implicitly the properties of the Fourier expansion of the integrand. Special rules, constructed from so-called optimal coefficients, give a particularly uniform distribution of the points throughout n -dimensional space and from their number theoretic properties minimize the error on a prescribed class of integrals. The method can be combined with the Monte Carlo procedure.

(d) Sag-Szekeres method

By transformation this method seeks to induce properties into the integrand which make it accurately integrable by the trapezoidal rule. The transformation also allows effective control over the number of integrand evaluations.

(e) Automatic adaptive procedures

An automatic adaptive strategy in several dimensions normally involves division of the region into subregions, concentrating the divisions in those parts of the region where the integrand is worst behaved. It is difficult to arrange with any generality for variable limits in the inner integral(s). For this reason, some methods use a region where all the limits are constants; this is called a hyper-rectangle. Integrals over regions defined by variable or infinite limits may be handled by transformation to a hyper-rectangle. Integrals over regions so irregular that such a transformation is not feasible may be handled by surrounding the region by an appropriate hyper-rectangle and defining the integrand to be zero outside the desired region. Such a technique should always be followed by a Monte Carlo method for integration.

The method used locally in each subregion produced by the adaptive subdivision process is usually one of three types: Monte Carlo, number theoretic or deterministic. Deterministic methods are usually the most rapidly convergent but are often expensive to use for high dimensionality and not as robust as the other techniques.

3. Recommendations on Choice and Use of Routines

The following three sub-sections consider in turn routines for: one-dimensional integrals over a finite interval, and over a semi-infinite or an infinite interval; and multi-dimensional integrals. Within each sub-section, routines are classified by the type of method, which ranges from simple rule evaluation to automatic adaptive algorithms. The recommendations apply particularly when the primary objective is simply to compute the value of one or more integrals, and in these cases the automatic adaptive routines are generally the most convenient and reliable, although also the most expensive in computing time.

Note however that in some circumstances it may be counter-

productive to use an automatic routine. If the results of the quadrature are to be used in turn as input to a further computation (e.g. an 'outer' quadrature or an optimization problem), then this further computation may be adversely affected by the 'jagged performance profile' of an automatic routine; a simple rule-evaluation routine may provide much better overall performance. For further guidance, the article Lyness [3] is recommended.

3.1. One-dimensional Integrals over a Finite Interval

(a) Integrand defined as a set of points

If $f(x)$ is defined numerically at four or more points, then the Gill-Miller finite difference method (D01GAF) should be used. The interval of integration is taken to coincide with the range of x -values of the points supplied. It is in the nature of this problem that any routine may be unreliable. In order to check results independently and so as to provide an alternative technique the user may fit the integrand by Chebyshev series using E02ADF and then use routines E02AJF and E02AKF to evaluate its integral (which need not be restricted to the range of the integration points, as is the case for D01GAF). A further alternative is to fit a cubic spline to the data using E02BAF and then to evaluate its integral using E02BDF.

(b) Integrand defined as a function

If the functional form of $f(x)$ is known, then one of the following approaches should be taken. They are arranged in the order from most specific to most general, hence the first applicable procedure in the list will be the most efficient. However, if the user does not wish to make any assumptions about the integrand, the most reliable routine to use will be D01AJF, although this will in general be less efficient for simple integrals.

(i) Rule-evaluation routines

If $f(x)$ is known to be sufficiently well-behaved (more precisely, can be closely approximated by a polynomial of moderate degree), a Gaussian routine with a suitable number of abscissae may be used.

D01BBF may be used if it is required to examine the weights and abscissae. In this case, the user should

write the code for the evaluation of quadrature summation (6).

(ii) Automatic adaptive routines

Firstly, several routines are available for integrands of the form $w(x)g(x)$ where $g(x)$ is a 'smooth' function (i.e., has no singularities, sharp peaks or violent oscillations in the interval of integration) and $w(x)$ is a weight function of one of the following forms:

$$\text{if } w(x) = (b-x)^{(\alpha)} (x-a)^{(\beta)} (\log(b-x))^k (\log(x-a))^l$$

where $k, l = 0$ or 1 , $(\alpha), (\beta) > -1$: use D01APF;

if $w(x) = 1/(x-c)$: use D01AQF (this integral is called the Hilbert transform of g);

if $w(x) = \cos((\omega)x)$ or $\sin((\omega)x)$: use D01ANF (this routine can also handle certain types of singularities in $g(x)$).

Secondly, there are some routines for general $f(x)$. If $f(x)$ is known to be free of singularities, though it may be oscillatory, D01AKF may be used.

The most powerful of the finite interval integration routine is D01AJF (which can cope with singularities of several types). It may be used if none of the more specific situations described above applies. D01AJF is very reliable, particularly where the integrand has singularities other than at an end-point, or has discontinuities or cusps, and is therefore recommended where the integrand is known to be badly-behaved, or where its nature is completely unknown.

Most of the routines in this chapter require the user to supply a function or subroutine to evaluate the integrand at a single point.

If $f(x)$ has singularities of certain types, discontinuities or sharp peaks occurring at known points, the integral should be evaluated separately over each of the subranges or D01ALF may be used.

3.2. One-dimensional Integrals over a Semi-infinite or Infinite Interval

(a) Integrand defined as a set of points

If $f(x)$ is defined numerically at four or more points, and the portion of the integral lying outside the range of the points supplied may be neglected, then the Gill-Miller finite difference method, D01GAF, should be used.

(b) Integrand defined as a function

(i) Rule evaluation routines

If $f(x)$ behaves approximately like a polynomial in x , apart from a weight function of the form

$$e^{-(\beta)x} \quad (\beta > 0 \text{ (semi-infinite interval, lower limit finite);})$$

$$\text{or } e^{-(\beta)x} \quad (\beta < 0 \text{ (semi-infinite interval, upper limit finite);})$$

$$\text{or } e^{-(\beta)(x-\alpha)^2} \quad (\beta > 0 \text{ (infinite interval);})$$

or if $f(x)$ behaves approximately like a x^{-1} polynomial in $(x+B)$ (semi-infinite range); then the Gaussian routines may be used.

D01BBF may be used if it is required to examine the weights and abscissae. In this case, the user should write the code for the evaluation of quadrature summation (6).

(ii) Automatic adaptive routines

D01AMF may be used, except for integrands which decay slowly towards an infinite end-point, and oscillate in sign over the entire range. For this class, it may be possible to calculate the integral by integrating between the zeros and invoking some extrapolation process.

D01ASF may be used for integrals involving weight functions of the form $\cos((\omega)x)$ and $\sin((\omega)x)$ over a semi-infinite interval (lower limit finite).

The following alternative procedures are mentioned for completeness, though their use will rarely be necessary:

- (1) If the integrand decays rapidly towards an infinite end-point, a finite cut-off may be chosen, and the finite range methods applied.
- (2) If the only irregularities occur in the finite part (apart from a singularity at the finite limit, with which D01AMF can cope), the range may be divided, with D01AMF used on the infinite part.
- (3) A transformation to finite range may be employed, e.g.

$$x = \frac{1-t}{t} \quad \text{or} \quad x = -\log t$$

will transform $(0, \infty)$ to $(1, 0)$ while for infinite ranges we have

$$\frac{\int_{-\infty}^{+\infty} f(x) dx}{\int_{-\infty}^{+\infty} [f(x)+f(-x)] dx} = \frac{\int_{-\infty}^{+\infty} f(x) dx}{\int_0^{\infty} f(x) dx + \int_0^{\infty} f(-x) dx}$$

If the integrand behaves badly on $(-\infty, 0)$ and well on $(0, \infty)$ or vice versa it is better to compute it as

$$\frac{\int_{-\infty}^0 f(x) dx + \int_0^{\infty} f(x) dx}{\int_{-\infty}^0 f(x) dx + \int_0^{\infty} f(x) dx}$$

This saves computing unnecessary function values in the semi-infinite range where the function is well behaved.

3.3. Multi-dimensional Integrals

A number of techniques are available in this area and the choice depends to a large extent on the dimension and the required

accuracy. It can be advantageous to use more than one technique as a confirmation of accuracy particularly for high dimensional integrations. Many of the routines incorporate the transformation procedure REGION which allows general product regions to be easily dealt with in terms of conversion to the standard n-cube region.

- (a) Products of one-dimensional rules (suitable for up to about 5 dimensions)

If $f(x_1, x_2, \dots, x_n)$ is known to be a sufficiently well-behaved function of each variable x_i , apart possibly from weight functions of the types provided, a product of Gaussian rules may be used. These are provided by D01BBF. In this case, the user should write the code for the evaluation of quadrature summation (6). Rules for finite, semi-infinite and infinite ranges are included.

The one-dimensional routines may also be used recursively. For example, the two-dimensional integral

$$I = \int_{a_1}^{b_1} \int_{a_2}^{b_2} f(x, y) dy dx$$

may be expressed as

$$I = \int_{a_1}^{b_1} F(x) dx,$$

where

$$F(x) = \int_{a_2}^{b_2} f(x, y) dy.$$

The user segment to evaluate $F(x)$ will call the integration

routine for the y-integration, which will call another user segment for $f(x,y)$ as a function of y (x being effectively a constant). Note that, as Fortran is not a recursive language, a different library integration routine must be used for each dimension. Apart from this restriction, the full range of one-dimensional routines are available, for finite/infinite intervals, constant/variable limits, rule evaluation/automatic strategies etc.

(b) Automatic routines (D01GBF and D01FCF)

Both routines are for integrals of the form

$$\int_{a_1}^{b_1} \int_{a_2}^{b_2} \dots \int_{a_n}^{b_n} f(x_1, x_2, \dots, x_n) dx_1 dx_2 \dots dx_n$$

D01GBF is an adaptive Monte Carlo routine. This routine is usually slow and not recommended for high accuracy work. It is a robust routine that can often be used for low accuracy results with highly irregular integrands or when n is large.

D01FCF is an adaptive deterministic routine. Convergence is fast for well-behaved integrands. Highly accurate results can often be obtained for n between 2 and 5, using significantly fewer integrand evaluations than would be required by D01GBF. The routine will usually work when the integrand is mildly singular and for $n \leq 10$ should be used before D01GBF. If it is known in advance that the integrand is highly irregular, it is best to compare results from at least two different routines.

There are many problems for which one or both of the routines will require large amounts of computing time to obtain even moderately accurate results. The amount of computing time is controlled by the number of integrand evaluations allowed by the user, and users should set this parameter carefully, with reference to the time available and the accuracy desired.

3.4. Decision Trees

(i) One-dimensional integrals over a finite interval. (If in doubt, follow the downward branch.)

Please see figure in printed Reference Manual

(ii) One-dimensional integrals over a semi-infinite or infinite interval. (If in doubt, follow the downward branch.)

Please see figure in printed Reference Manual

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D01AJF is a general-purpose integrator which calculates an approximation to the integral of a function $f(x)$ over a finite interval $[a,b]$:

$$I = \int_a^b f(x) dx.$$

2. Specification

```
SUBROUTINE D01AJF (F, A, B, EPSABS, EPSREL, RESULT,
1                ABSERR, W, LW, IW, LIW, IFAIL)
INTEGER          LW, IW(LIW), LIW, IFAIL
DOUBLE PRECISION F, A, B, EPSABS, EPSREL, RESULT, ABSERR, W
1                (LW)
EXTERNAL         F
```

3. Description

D01AJF is based upon the QUADPACK routine QAGS (Piessens et al [3]). It is an adaptive routine, using the Gauss 10-point and Kronrod 21-point rules. The algorithm, described by de Doncker [1], incorporates a global acceptance criterion (as defined by Malcolm and Simpson [2]) together with the (epsilon)-algorithm (Wynn [4]) to perform extrapolation. The local error estimation is described by Piessens et al [3].

The routine is suitable as a general purpose integrator, and can be used when the integrand has singularities, especially when these are of algebraic or logarithmic type.

D01AJF requires the user to supply a function to evaluate the integrand at a single point.

The routine D01ATF(*) uses an identical algorithm but requires the user to supply a subroutine to evaluate the integrand at an array of points. Therefore D01ATF(*) will be more efficient if the evaluation can be performed in vector mode on a vector-processing machine.

5. Parameters

- 1: F -- DOUBLE PRECISION FUNCTION, supplied by the user.
External Procedure
F must return the value of the integrand f at a given point.

Its specification is:

DOUBLE PRECISION FUNCTION F (X)
DOUBLE PRECISION X

- 1: X -- DOUBLE PRECISION Input
On entry: the point at which the integrand f must be evaluated.
F must be declared as EXTERNAL in the (sub)program from which D01AJF is called. Parameters denoted as Input must not be changed by this procedure.
- 2: A -- DOUBLE PRECISION Input
On entry: the lower limit of integration, a.
- 3: B -- DOUBLE PRECISION Input
On entry: the upper limit of integration, b. It is not necessary that a<b.
- 4: EPSABS -- DOUBLE PRECISION Input
On entry: the absolute accuracy required. If EPSABS is negative, the absolute value is used. See Section 7.
- 5: EPSREL -- DOUBLE PRECISION Input
On entry: the relative accuracy required. If EPSREL is negative, the absolute value is used. See Section 7.
- 6: RESULT -- DOUBLE PRECISION Output
On exit: the approximation to the integral I.
- 7: ABSERR -- DOUBLE PRECISION Output
On exit: an estimate of the modulus of the absolute error, which should be an upper bound for |I-RESULT|.
- 8: W(LW) -- DOUBLE PRECISION array Output
On exit: details of the computation, as described in Section 8.
- 9: LW -- INTEGER Input
On entry:
the dimension of the array W as declared in the (sub)program from which D01AJF is called.
The value of LW (together with that of LIW below) imposes a bound on the number of sub-intervals into which the interval of integration may be divided by the routine. The number of sub-intervals cannot exceed LW/4. The more difficult the

integrand, the larger LW should be. Suggested value: a value in the range 800 to 2000 is adequate for most problems.
 Constraint: $LW \geq 4$.

10: IW(LIW) -- INTEGER array Output
 On exit: IW(1) contains the actual number of sub-intervals used. The rest of the array is used as workspace.

11: LIW -- INTEGER Input
 On entry:
 the dimension of the array IW as declared in the
 (sub)program from which D01AJF is called.
 The number of sub-intervals into which the interval of
 integration may be divided cannot exceed LIW. Suggested
 value: $LIW = LW/4$. Constraint: $LIW \geq 1$.

12: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. Users who are
 unfamiliar with this parameter should refer to the Essential
 Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or
 gives a warning (see Section 6).

For this routine, because the values of output parameters
 may be useful even if IFAIL \neq 0 on exit, users are
 recommended to set IFAIL to -1 before entry. It is then
 essential to test the value of IFAIL on exit.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
 output on the current error message unit (as defined by X04AAF).

IFAIL= 1

The maximum number of subdivisions allowed with the given
 workspace has been reached without the accuracy requirements
 being achieved. Look at the integrand in order to determine
 the integration difficulties. If the position of a local
 difficulty within the interval can be determined (e.g. a
 singularity of the integrand or its derivative, a peak, a
 discontinuity, etc) you will probably gain from splitting up
 the interval at this point and calling the integrator on the
 subranges. If necessary, another integrator, which is

designed for handling the type of difficulty involved, must be used. Alternatively, consider relaxing the accuracy requirements specified by EPSABS and EPSREL, or increasing the amount of workspace.

IFAIL= 2

Round-off error prevents the requested tolerance from being achieved. The error may be under-estimated. Consider requesting less accuracy.

IFAIL= 3

Extremely bad local integrand behaviour causes a very strong subdivision around one (or more) points of the interval.

IFAIL= 4

The requested tolerance cannot be achieved, because the extrapolation does not increase the accuracy satisfactorily; the returned result is the best which can be obtained. The same advice applies as in the case of IFAIL = 1.

IFAIL= 5

The integral is probably divergent, or slowly convergent. Please note that divergence can occur with any non-zero value of IFAIL.

IFAIL= 6

On entry $LW < 4$,
or $LIW < 1$.

7. Accuracy

The routine cannot guarantee, but in practice usually achieves, the following accuracy:

$$|I-RESULT| \leq tol,$$

where

$$tol = \max\{|EPSABS|, |EPSREL| * |I|\},$$

and EPSABS and EPSREL are user-specified absolute and relative error tolerance. Moreover it returns the quantity ABSERR which, in normal circumstances, satisfies

$$|I-RESULT| \leq ABSERR \leq tol.$$

8. Further Comments

The time taken by the routine depends on the integrand and the accuracy required.

If IFAIL $\neq 0$ on exit, then the user may wish to examine the contents of the array W, which contains the end-points of the sub-intervals used by D01AJF along with the integral contributions and error estimates over the sub-intervals.

Specifically, for $i=1,2,\dots,n$, let r_i denote the approximation to the value of the integral over the sub-interval $[a_i, b_i]$ in the partition of $[a,b]$ and e_i be the corresponding absolute error estimate.

Then, $\int_a^b f(x)dx \approx \sum_{i=1}^n r_i$ and $\text{RESULT} = \sum_{i=1}^n r_i$, unless D01AJF terminates while testing for divergence of the integral (see Piessens et al [3], Section 3.4.3). In this case, RESULT (and ABSERR) are taken to be the values returned from the extrapolation process. The value of n is returned in IW(1), and the values a_i, b_i, e_i and r_i are stored consecutively in the array W, that is:

```

a_i = W(i),
b_i = W(n+i),
e_i = W(2n+i) and
r_i = W(3n+i).

```

9. Example

To compute

$$\frac{\int_0^{2(\pi)} \frac{x \sin(30x)}{(1 - \frac{x^2}{(2(\pi))^2})} dx}{\sqrt{(2(\pi))^2}}$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

D01AKF

D01AKF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D01AKF is an adaptive integrator, especially suited to oscillating, non-singular integrands, which calculates an approximation to the integral of a function $f(x)$ over a finite interval $[a,b]$:

$$I = \int_a^b f(x) dx.$$

2. Specification

```

SUBROUTINE D01AKF (F, A, B, EPSABS, EPSREL, RESULT,
1                ABSERR, W, LW, IW, LIW, IFAIL)
INTEGER          LW, IW(LIW), LIW, IFAIL
DOUBLE PRECISION F, A, B, EPSABS, EPSREL, RESULT, ABSERR, W
1                (LW)
```

EXTERNAL F

3. Description

D01AKF is based upon the QUADPACK routine QAG (Piessens et al [3]). It is an adaptive routine, using the Gauss 30-point and Kronrod 61-point rules. A 'global' acceptance criterion (as defined by Malcolm and Simpson [1]) is used. The local error estimation is described in Piessens et al [3].

Because this routine is based on integration rules of high order, it is especially suitable for non-singular oscillating integrands.

D01AKF requires the user to supply a function to evaluate the integrand at a single point.

The routine D01AUF(*) uses an identical algorithm but requires the user to supply a subroutine to evaluate the integrand at an array of points. Therefore D01AUF(*) will be more efficient if the evaluation can be performed in vector mode on a vector-processing machine.

D01AUF(*) also has an additional parameter KEY which allows the user to select from six different Gauss-Kronrod rules.

5. Parameters

- 1: F -- DOUBLE PRECISION FUNCTION, supplied by the user.

External Procedure

 F must return the value of the integrand f at a given point.

Its specification is:

DOUBLE PRECISION FUNCTION F (X)
DOUBLE PRECISION X

- 1: X -- DOUBLE PRECISION Input
On entry: the point at which the integrand f must be evaluated.
F must be declared as EXTERNAL in the (sub)program from which D01AKF is called. Parameters denoted as Input must not be changed by this procedure.

- 2: A -- DOUBLE PRECISION Input
On entry: the lower limit of integration, a.

- 3: B -- DOUBLE PRECISION Input
On entry: the upper limit of integration, b. It is not necessary that a<b.

- 4: EPSABS -- DOUBLE PRECISION Input
On entry: the absolute accuracy required. If EPSABS is negative, the absolute value is used. See Section 7.

- 5: EPSREL -- DOUBLE PRECISION Input
On entry: the relative accuracy required. If EPSREL is negative, the absolute value is used. See Section 7.

- 6: RESULT -- DOUBLE PRECISION Output
On exit: the approximation to the integral I.

- 7: ABSERR -- DOUBLE PRECISION Output
On exit: an estimate of the modulus of the absolute error, which should be an upper bound |I-RESULT|.

- 8: W(LW) -- DOUBLE PRECISION array Output
On exit: details of the computation, as described in Section 8.

- 9: LW -- INTEGER Input
On entry: the dimension of W, as declared in the (sub) program from which D01AKF is called. The value of LW (together with that of LIW below) imposes a bound on the number of sub-intervals into which the interval of integration may be divided by the routine. The number of sub-intervals cannot exceed LW/4. The more difficult the integrand, the larger LW should be. Suggested value: a value in the range 800 to 2000 is adequate for most problems.

Constraint: $LW \geq 4$. See IW below.

10: IW(LIW) -- INTEGER array Output
 On exit: IW(1) contains the actual number of sub-intervals used. The rest of the array is used as workspace.

11: LIW -- INTEGER Input
 On entry:
 the dimension of the array IW as declared in the (sub)program from which D01AKF is called.
 The number of sub-intervals into which the interval of integration may be divided cannot exceed LIW. Suggested value: $LIW = LW/4$. Constraint: $LIW \geq 1$.

12: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL \neq 0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

The maximum number of subdivisions allowed with the given workspace has been reached without the accuracy requirements being achieved. Look at the integrand in order to determine the integration difficulties. Probably another integrator which is designed for handling the type of difficulty involved must be used. Alternatively, consider relaxing the accuracy requirements specified by EPSABS and EPSREL, or increasing the amount of workspace.

IFAIL= 2

Round-off error prevents the requested tolerance from being

achieved. Consider requesting less accuracy.

IFAIL= 3

Extremely bad local integrand behaviour causes a very strong subdivision around one (or more) points of the interval.
The same advice applies as in the case of IFAIL = 1.

IFAIL= 4

On entry $LW < 4$,

or $LIW < 1$.

7. Accuracy

The routine cannot guarantee, but in practice usually achieves, the following accuracy:

$$|I-RESULT| \leq \text{tol},$$

where

$$\text{tol} = \max\{|\text{EPSABS}|, |\text{EPSREL}| * |I|\},$$

and EPSABS and EPSREL are user-specified absolute and relative error tolerances. Moreover it returns the quantity ABSERR which, in normal circumstances satisfies

$$|I-RESULT| \leq \text{ABSERR} \leq \text{tol}.$$

8. Further Comments

The time taken by the routine depends on the integrand and the accuracy required.

If IFAIL \neq 0 on exit, then the user may wish to examine the contents of the array W, which contains the end-points of the sub-intervals used by D01AKF along with the integral contributions and error estimates over these sub-intervals.

Specifically, for $i=1,2,\dots,n$, let r_i denote the approximation to the value of the integral over the sub-interval $[a_i, b_i]$ in the partition of $[a,b]$ and e_i be the corresponding absolute error

estimate. Then, $\int_a^b f(x) dx \approx r$ and $RESULT = \sum_{i=1}^n r_i$. The value of n is returned in $IW(1)$, and the values a_i , b_i , e_i and r_i are stored consecutively in the array W , that is:

```

a =W(i),
i

b =W(n+i),
i

e =W(2n+i) and
i

r =W(3n+i).
i

```

9. Example

To compute

$$\int_0^{2(\pi)} x \sin(30x) \cos x \, dx.$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

D01ALF

D01ALF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is

not included in the Foundation Library.

1. Purpose

D01ALF is a general purpose integrator which calculates an approximation to the integral of a function $f(x)$ over a finite interval $[a,b]$:

$$I = \int_a^b f(x) dx$$

where the integrand may have local singular behaviour at a finite number of points within the integration interval.

2. Specification

```

SUBROUTINE D01ALF (F, A, B, NPTS, POINTS, EPSABS, EPSREL,
1                RESULT, ABSERR, W, LW, IW, LIW, IFAIL)
  INTEGER          NPTS, LW, IW(LIW), LIW, IFAIL
  DOUBLE PRECISION F, A, B, POINTS(*), EPSABS, EPSREL,
1                RESULT, ABSERR, W(LW)
  EXTERNAL          F

```

3. Description

D01ALF is based upon the QUADPACK routine QAGP (Piessens et al [3]). It is very similar to D01AJF, but allows the user to supply difficult. It is an adaptive routine, using the Gauss 10-point and Kronrod 21-point rules. The algorithm described by de Doncker [1], incorporates a global acceptance criterion (as defined by Malcolm and Simpson [2]) together with the (epsilon)-algorithm (Wynn [4]) to perform extrapolation. The user-supplied 'break-points' always occur as the end-points of some sub-interval during the adaptive process. The local error estimation is described by Piessens et al [3].

5. Parameters

- 1: F -- DOUBLE PRECISION FUNCTION, supplied by the user.

External Procedure

 F must return the value of the integrand f at a given point.

Its specification is:

DOUBLE PRECISION FUNCTION F (X)
 DOUBLE PRECISION X

- 1: X -- DOUBLE PRECISION Input
 On entry: the point at which the integrand f must be evaluated.
 F must be declared as EXTERNAL in the (sub)program from which D01ALF is called. Parameters denoted as Input must not be changed by this procedure.
- 2: A -- DOUBLE PRECISION Input
 On entry: the lower limit of integration, a.
- 3: B -- DOUBLE PRECISION Input
 On entry: the upper limit of integration, b. It is not necessary that a<b.
- 4: NPTS -- INTEGER Input
 On entry: the number of user-supplied break-points within the integration interval. Constraint: NPTS >= 0.
- 5: POINTS(NPTS) -- DOUBLE PRECISION array Input
 On entry: the user-specified break-points. Constraint: the break-points must all lie within the interval of integration (but may be supplied in any order).
- 6: EPSABS -- DOUBLE PRECISION Input
 On entry: the absolute accuracy required. If EPSABS is

negative, the absolute value is used. See Section 7.

- 7: EPSREL -- DOUBLE PRECISION Input
 On entry: the relative accuracy required. If EPSREL is negative, the absolute value is used. See Section 7.

- 8: RESULT -- DOUBLE PRECISION Input
 On entry: the approximation to the integral I.

- 9: ABSERR -- DOUBLE PRECISION Output
 On exit: an estimate of the modulus of the absolute error, which should be an upper bound for $|I - \text{RESULT}|$.

- 10: W(LW) -- DOUBLE PRECISION array Output
 On exit: details of the computation, as described in Section 8.

- 11: LW -- INTEGER Input
 On entry:
 the dimension of the array W as declared in the (sub)program from which D01ALF is called.
 The value of LW (together with that of LIW below) imposes a bound on the number of sub-intervals into which the interval of integration may be divided by the routine. The number of sub-intervals cannot exceed $(LW - 2 * NPTS - 4) / 4$. The more difficult the integrand, the larger LW should be. Suggested value: a value in the range 800 to 2000 is adequate for most problems. Constraint: $LW \geq 2 * NPTS + 8$.

- 12: IW(LIW) -- INTEGER array Output
 On exit: IW(1) contains the actual number of sub-intervals used. The rest of the array is used as workspace.

- 13: LIW -- INTEGER Input
 On entry:
 the dimension of the array IW as declared in the (sub)program from which D01ALF is called.
 The number of sub-intervals into which the interval of integration may be divided cannot exceed $(LIW - NPTS - 2) / 2$. Suggested value: $LIW = LW / 2$. Constraint: $LIW \geq NPTS + 4$.

- 14: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL \neq 0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

The maximum number of subdivisions allowed with the given workspace has been reached, without the accuracy requirements being achieved. Look at the integrand in order to determine the integration difficulties. If the position of a local difficulty within the interval can be determined (e.g. a singularity of the integrand or its derivative, a peak, a discontinuity, etc) it should be supplied to the routine as an element of the vector POINTS. If necessary, another integrator should be used, which is designed for handling the type of difficulty involved. Alternatively, consider relaxing the accuracy requirements specified by EPSABS and EPSREL, or increasing the amount of workspace.

IFAIL= 2

Round-off error prevents the requested tolerance from being achieved. The error may be under-estimated. Consider requesting less accuracy.

IFAIL= 3

Extremely bad local integrand behaviour causes a very strong subdivision around one (or more) points of the interval. The same advice applies as in the case of IFAIL = 1.

IFAIL= 4

The requested tolerance cannot be achieved, because the extrapolation does not increase the accuracy satisfactorily; the result returned is the best which can be obtained. The same advice applies as in the case IFAIL = 1.

IFAIL= 5

The integral is probably divergent, or slowly convergent. Please note that divergence can also occur with any other non-zero value of IFAIL.

IFAIL= 6

The input is invalid: break-points are specified outside the integration range, NPTS > LIMIT or NPTS < 0. RESULT and ABSERR are set to zero.

IFAIL= 7

On entry LW<2*NPTS+8,

or LIW<NPTS+4.

7. Accuracy

The routine cannot guarantee, but in practice usually achieves, the following accuracy:

$$|I - \text{RESULT}| \leq \text{tol},$$

where

$$\text{tol} = \max\{|\text{EPSABS}|, |\text{EPSREL}| * |I|\},$$

and EPSABS and EPSREL are user-specified absolute and relative error tolerances. Moreover it returns the quantity ABSERR which, in normal circumstances, satisfies

$$|I - \text{RESULT}| \leq \text{ABSERR} \leq \text{tol}.$$

8. Further Comments

The time taken by the routine depends on the integrand and on the accuracy required.

If IFAIL \neq 0 on exit, then the user may wish to examine the contents of the array W, which contains the end-points of the sub-intervals used by D01ALF along with the integral contributions and error estimates over these sub-intervals.

Specifically, for $i=1,2,\dots,n$, let r_i denote the approximation to the value of the integral over the sub-interval $[a_i, b_i]$ in the partition of $[a,b]$ and e_i be the corresponding absolute error

D01 -- Quadrature D01AMF
D01AMF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D01AMF calculates an approximation to the integral of a function $f(x)$ over an infinite or semi-infinite interval $[a,b]$:

$$I = \int_a^b f(x) dx$$

2. Specification

```

SUBROUTINE D01AMF (F, BOUND, INF, EPSABS, EPSREL, RESULT,
1              ABSERR, W, LW, IW, LIW, IFAIL)
  INTEGER      INF, LW, IW(LIW), LIW, IFAIL
  DOUBLE PRECISION F, BOUND, EPSABS, EPSREL, RESULT, ABSERR,
1              W(LW)
  EXTERNAL      F

```

3. Description

D01AMF is based on the QUADPACK routine QAGI (Piessens et al [3]) [0,1] using one of the identities:

$$\int_{-\infty}^{\infty} f(x) dx = \int_{-\infty}^{\infty} f(a - t) dt = \int_{-\infty}^{\infty} f(a + t) dt$$

$$\int_a^{\infty} f(x) dx = \int_0^{\infty} (f(x) + f(-x)) dx = \int_0^1 \left[f\left(\frac{1-t}{t}\right) + f\left(\frac{-1+t}{t}\right) \right] \frac{1}{t^2} dt$$

where a represents a finite integration limit. An adaptive procedure, based on the Gauss seven-point and Kronrod 15-point rules, is then employed on the transformed integral. The algorithm, described by de Doncker [1], incorporates a global acceptance criterion (as defined by Malcolm and Simpson [2]) together with the (epsilon)-algorithm (Wynn [4]) to perform extrapolation. The local error estimation is described by Piessens et al [3].

5. Parameters

- 1: F -- DOUBLE PRECISION FUNCTION, supplied by the user.
External Procedure
On entry: the point at which the integrand f must be evaluated.

Its specification is:

```
DOUBLE PRECISION FUNCTION F (X)
DOUBLE PRECISION X
```

- 1: X -- DOUBLE PRECISION Input
 On entry: the point at which the integrand f must be evaluated.
 F must be declared as EXTERNAL in the (sub)program from which D01AMF is called. Parameters denoted as Input must not be changed by this procedure.

- 2: BOUND -- DOUBLE PRECISION Input
 On entry: the finite limit of the integration range (if present). BOUND is not used if the interval is doubly infinite.

- 3: INF -- INTEGER Input
 On entry: indicates the kind of integration range:
 if INF =1, the range is [BOUND, +infty)

 if INF =-1, the range is (-infty, BOUND]

 if INF =+2, the range is (-infty, +infty).
 Constraint: INF =-1, 1 or 2.

- 4: EPSABS -- DOUBLE PRECISION Input
 On entry: the absolute accuracy required. If EPSABS is negative, the absolute value is used. See Section 7.

- 5: EPSREL -- DOUBLE PRECISION Input
 On entry: the relative accuracy required. If EPSREL is negative, the absolute value is used. See Section 7.

- 6: RESULT -- DOUBLE PRECISION Output
 On exit: the approximation to the integral I .

- 7: ABSERR -- DOUBLE PRECISION Output
 On exit: an estimate of the modulus of the absolute error, which should be an upper bound for $|I-RESULT|$.

- 8: W(LW) -- DOUBLE PRECISION array Output
 On exit: details of the computation, as described in Section 8.

- 9: LW -- INTEGER Input
 On entry:
 the dimension of the array W as declared in the (sub)program from which D01AMF is called.
 The value of LW (together with that of LIW below) imposes a bound on the number of sub-intervals into which the interval

of integration may be divided by the routine. The number of sub-intervals cannot exceed $LW/4$. The more difficult the integrand, the larger LW should be. Suggested value: a value in the range 800 to 2000 is adequate for most problems. Constraint: $LW \geq 4$.

- 10: $IW(LIW)$ -- INTEGER array Output
 On exit: $IW(1)$ contains the actual number of sub-intervals used. The rest of the array is used as workspace.
- 11: LIW -- INTEGER Input
 On entry:
 the dimension of the array IW as declared in the (sub)program from which $D01AMF$ is called.
 The number of sub-intervals into which the interval of integration may be divided cannot exceed LIW . Suggested value: $LIW = LW/4$. Constraint: $LIW \geq 1$.
- 12: $IFAIL$ -- INTEGER Input/Output
 On entry: $IFAIL$ must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.
 On exit: $IFAIL = 0$ unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if $IFAIL \neq 0$ on exit, users are recommended to set $IFAIL$ to -1 before entry. It is then essential to test the value of $IFAIL$ on exit.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry $IFAIL = 0$ or -1, explanatory error messages are output on the current error message unit (as defined by $X04AAF$).

$IFAIL = 1$

The maximum number of subdivisions allowed with the given workspace has been reached without the requested accuracy requirements being achieved. Look at the integrand in order to determine the integration difficulties. If the position of a local difficulty within the interval can be determined (e.g. a singularity of the integrand or its derivative, a peak, a discontinuity, etc) you will probably gain from splitting up the interval at this point and calling $D01AMF$

on the infinite subrange and an appropriate integrator on the finite subrange. Alternatively, consider relaxing the accuracy requirements specified by EPSABS and EPSREL, or increasing the amount of workspace.

IFAIL= 2

Round-off error prevents the requested tolerance from being achieved. The error may be underestimated. Consider requesting less accuracy.

IFAIL= 3

Extremely bad local integrand behaviour causes a very strong subdivision around one (or more) points of the interval. The same advice applies as in the case of IFAIL = 1.

IFAIL= 4

The requested tolerance cannot be achieved, because the extrapolation does not increase the accuracy satisfactorily; the returned result is the best which can be obtained. The same advice applies as in the case of IFAIL = 1.

IFAIL= 5

The integral is probably divergent, or slowly convergent. It must be noted that divergence can also occur with any other non-zero value of IFAIL.

IFAIL= 6

On entry LW < 4,

or LIW < 1,

or INF /= -1, 1 or 2.

Please note that divergence can occur with any non-zero value of IFAIL.

7. Accuracy

The routine cannot guarantee, but in practice usually achieves, the following accuracy:

$$|I-RESULT| \leq \text{tol},$$

where

$$\text{tol} = \max\{|\text{EPSABS}|, |\text{EPSREL}| * |I|\},$$

and EPSABS and EPSREL are user-specified absolute and relative error tolerances. Moreover it returns the quantity ABSERR, which, in normal circumstances, satisfies

$$|I - \text{RESULT}| \leq \text{ABSERR} \leq \text{tol}.$$

8. Further Comments

The time taken by the routine depends on the integrand and the accuracy required.

If IFAIL $\neq 0$ on exit, then the user may wish to examine the contents of the array W, which contains the end-points of the sub-intervals used by D01AMF along with the integral contributions and error estimates over these sub-intervals.

Specifically, for $i=1,2,\dots,n$, let r_i denote the approximation to the value of the integral over the sub-interval $[a_i, b_i]$ in the partition of $[a,b]$ and e_i be the corresponding absolute error

estimate. Then,
$$\int_a^b f(x) dx \approx \sum_{i=1}^n r_i \quad \text{and} \quad \text{RESULT} = \sum_{i=1}^n r_i \quad \text{unless D01AMF}$$

terminates while testing for divergence of the integral (see Piessens et al [3] Section 3.4.3). In this case, RESULT (and ABSERR) are taken to be the values returned from the extrapolation process. The value of n is returned in IW(1), and the values a_i, b_i, e_i and r_i are stored consecutively in the array W, that is:

$$a_i = W(i), b_i = W(n+i), e_i = W(2n+i) \quad \text{and} \quad r_i = W(3n+i).$$

Note: that this information applies to the integral transformed to (0,1) as described in Section 3, not to the original integral.

9. Example

To compute

The exact answer is (π) .

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

```

D01ANF(3NAG)          Foundation Library (12/10/92)          D01ANF(3NAG)

      D01 -- Quadrature                                         D01ANF
      D01ANF -- NAG Foundation Library Routine Document

```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D01ANF calculates an approximation to the sine or the cosine transform of a function g over $[a,b]$:

$$I = \int_a^b |g(x)| |\sin((\omega) x)| dx \quad \text{or} \quad I = \int_a^b |g(x)| |\cos((\omega) x)| dx$$

(for a user-specified value of ω)).

2. Specification

```

SUBROUTINE DO1ANF (G, A, B, OMEGA, KEY, EPSABS, EPSREL,
1             RESULT, ABSERR, W, LW, IW, LIW, IFAIL)
  INTEGER      KEY, LW, IW(LIW), LIW, IFAIL
  DOUBLE PRECISION G, A, B, OMEGA, EPSABS, EPSREL, RESULT,
1             ABSERR, W(LW)
  EXTERNAL     G

```

3. Description

D01ANF is based upon the QUADPACK routine QFOUR (Piessens et al [3]). It is an adaptive routine, designed to integrate a function of the form $g(x)w(x)$, where $w(x)$ is either $\sin((\omega)x)$ or $\cos((\omega)x)$. If a sub-interval has length

$$L = \frac{b-a}{2^{-1}}$$

then the integration over this sub-interval is performed by means of a modified Clenshaw-Curtis procedure (Piessens and Branders [2]) if $L(\omega) > 4$ and $l \leq 20$. In this case a Chebyshev-series approximation of degree 24 is used to approximate $g(x)$, while an error estimate is computed from this approximation together with that obtained using Chebyshev-series of degree 12. If the above conditions do not hold then Gauss 7-point and Kronrod 15-point rules are used. The algorithm, described in [3], incorporates a global acceptance criterion (as defined in Malcolm and Simpson [1]) together with the (epsilon)-algorithm Wynn [4] to perform extrapolation. The local error estimation is described in [3].

5. Parameters

- 1: G -- DOUBLE PRECISION FUNCTION, supplied by the user.

External Procedure

 G must return the value of the function g at a given point.

Its specification is:

DOUBLE PRECISION FUNCTION G (X)
DOUBLE PRECISION X

- 1: X -- DOUBLE PRECISION Input
On entry: the point at which the function g must be evaluated.
G must be declared as EXTERNAL in the (sub)program from which D01ANF is called. Parameters denoted as Input must not be changed by this procedure.
- 2: A -- DOUBLE PRECISION Input
On entry: the lower limit of integration, a.
- 3: B -- DOUBLE PRECISION Input
On entry: the upper limit of integration, b. It is not necessary that $a < b$.
- 4: OMEGA -- DOUBLE PRECISION Input
On entry: the parameter (omega) in the weight function of the transform.
- 5: KEY -- INTEGER Input
On entry: indicates which integral is to be computed:
if KEY = 1, $w(x) = \cos((\omega)x)$;

if KEY = 2, $w(x) = \sin((\omega)x)$.
Constraint: KEY = 1 or 2.
- 6: EPSABS -- DOUBLE PRECISION Input
On entry: the absolute accuracy required. If EPSABS is negative, the absolute value is used. See Section 7.
- 7: EPSREL -- DOUBLE PRECISION Input
On entry: the relative accuracy required. If EPSREL is negative, the absolute value is used. See Section 7.
- 8: RESULT -- DOUBLE PRECISION Output
On exit: the approximation to the integral I.
- 9: ABSERR -- DOUBLE PRECISION Output
On exit: an estimate of the modulus of the absolute error, which should be an upper bound for $|I - \text{RESULT}|$.
- 10: W(LW) -- DOUBLE PRECISION array Output

On exit: details of the computation, as described in Section 8.

- 11: LW -- INTEGER Input
 On entry:
 the dimension of the array W as declared in the (sub)program from which D01ANF is called.
 The value of LW (together with that of LIW below) imposes a bound on the number of sub-intervals into which the interval of integration may be divided by the routine. The number of sub-intervals cannot exceed LW/4. The more difficult the integrand, the larger LW should be. Suggested value: a value in the range 800 to 2000 is adequate for most problems.
 Constraint: LW \geq 4.
- 12: IW(LIW) -- INTEGER array Output
 On exit: IW(1) contains the actual number of sub-intervals used. The rest of the array is used as workspace.
- 13: LIW -- INTEGER Input
 On entry:
 the dimension of the array IW as declared in the (sub)program from which D01ANF is called.
 The number of sub-intervals into which the interval of integration may be divided cannot exceed LIW/2. Suggested value: LIW = LW/2. Constraint: LIW \geq 2.
- 14: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.
- On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL \neq 0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

The maximum number of subdivisions allowed with the given workspace has been reached without the accuracy requested being achieved. Look at the integrand in order to determine the integration difficulties. If the position of a local difficulty within the interval can be determined (e.g. a singularity of the integrand or its derivative, a peak, a discontinuity, etc) you will probably gain from splitting up the interval at this point and calling the integrator on the subranges. If necessary, another integrator, which is designed for handling the type of difficulty involved, must be used. Alternatively consider relaxing the accuracy requirements specified by EPSABS and EPSREL, or increasing amount of workspace.

IFAIL= 2

Round-off error prevents the requested tolerance from being achieved. The error may be underestimated. Consider requesting less accuracy.

IFAIL= 3

Extremely bad local behaviour of $g(x)$ causes a very strong subdivision around one (or more) points of the interval. The same advice applies as in the case of IFAIL = 1.

IFAIL= 4

The requested tolerance cannot be achieved because the extrapolation does not increase the accuracy satisfactorily; the returned result is the best which can be obtained. The same advice applies as in the case of IFAIL = 1.

IFAIL= 5

The integral is probably divergent, or slowly convergent. It must be noted that divergence can occur with any non-zero value of IFAIL.

IFAIL= 6

On entry KEY < 1,
or KEY > 2.

IFAIL= 7

On entry LW < 4,
or LIW < 2.

7. Accuracy

The routine cannot guarantee, but in practice usually achieves, the following accuracy:

$$|I - \text{RESULT}| \leq \text{tol},$$

where

$$\text{tol} = \max\{|\text{EPSABS}|, |\text{EPSREL}| * |I|\},$$

and EPSABS and EPSREL are user-specified absolute and relative tolerances. Moreover it returns the quantity ABSERR, which, in normal circumstances, satisfies

$$|I - \text{RESULT}| \leq \text{ABSERR} \leq \text{tol}.$$

8. Further Comments

The time taken by the routine depends on the integrand and on the accuracy required.

If IFAIL \neq 0 on exit, then the user may wish to examine the contents of the array W, which contains the end-points of the sub-intervals used by D01ANF along with the integral contributions and error estimates over these sub-intervals.

Specifically, for $i=1,2,\dots,n$, let r_i denote the approximation to the value of the integral over the sub-interval $[a_i, b_i]$ in the partition of $[a,b]$ and e_i be the corresponding absolute error estimate. Then,

$$\int_a^b g(x)w(x)dx \sim r_i \quad \text{and} \quad \text{RESULT} = \sum_{i=1}^n r_i \quad \text{unless D01ANF terminates while testing for divergence of the integral (see Piessens et al [3] Section 3.4.3). In this case, RESULT (and ABSERR) are taken to be the values returned from the extrapolation process. The value of } n \text{ is returned in IW(1), and the values } a, b, e \text{ and } r \text{ are stored consecutively in the}$$

terminates while testing for divergence of the integral (see Piessens et al [3] Section 3.4.3). In this case, RESULT (and ABSERR) are taken to be the values returned from the extrapolation process. The value of n is returned in IW(1), and the values a, b, e and r are stored consecutively in the

$$r_i = W(3n+i).$$

DO1APF is an adaptive integrator which calculates an approximation to the integral of a function $g(x)w(x)$ over a finite interval $[a,b]$:

$$I = \frac{\int_a^b g(x)w(x)dx}{\int_a^b w(x)dx}$$

where the weight function w has end-point singularities of algebraico-logarithmic type.

2. Specification

```

SUBROUTINE D01APF (G, A, B, ALFA, BETA, KEY, EPSABS,
1                EPSREL, RESULT, ABSERR, W, LW, IW, LIW,
2                IFAIL)
  INTEGER          KEY, LW, IW(LIW), LIW, IFAIL
  DOUBLE PRECISION G, A, B, ALFA, BETA, EPSABS, EPSREL,
1                RESULT, ABSERR, W(LW)
  EXTERNAL          G

```

3. Description

D01APF is based upon the QUADPACK routine QAWSE (Piessens et al [3]) and integrates a function of the form $g(x)w(x)$, where the weight function $w(x)$ may have algebraico-logarithmic singularities at the end-points a and/or b . The strategy is a modification of that in D01AKF. We start by bisecting the original interval and applying modified Clenshaw-Curtis integration of orders 12 and 24 to both halves. Clenshaw-Curtis integration is then used on all sub-intervals which have a or b as one of their end-points (Piessens et al [2]). On the other sub-intervals Gauss-Kronrod (7-15 point) integration is carried out.

A 'global' acceptance criterion (as defined by Malcolm and Simpson [1]) is used. The local error estimation control is described by Piessens et al [3].

 On entry: the parameter (alpha) in the weight function.
 Constraint: ALFA > -1.
- 5: BETA -- DOUBLE PRECISION Input
 On entry: the parameter (beta) in the weight function.
 Constraint: BETA > -1.
- 6: KEY -- INTEGER Input
 On entry: indicates which weight function is to be used:
(alpha) (beta)
 if KEY = 1, $w(x) = (x-a)^{(\alpha)} (b-x)^{(\beta)}$
(alpha) (beta)

```

if KEY = 2, w(x)=(x-a)      (b-x)      ln(x-a)

if KEY = 3, w(x)=(x-a)      (alpha)    (beta)
                        (b-x)      ln(b-x)

if KEY = 4, w(x)=(x-a)      (alpha)    (beta)
                        (b-x)      ln(x-a)ln(b-x)

```

Constraint: KEY = 1, 2, 3 or 4

- 7: EPSABS -- DOUBLE PRECISION Input
 On entry: the absolute accuracy required. If EPSABS is negative, the absolute value is used. See Section 7.
- 8: EPSREL -- DOUBLE PRECISION Input
 On entry: the relative accuracy required. If EPSREL is negative, the absolute value is used. See Section 7.
- 9: RESULT -- DOUBLE PRECISION Output
 On exit: the approximation to the integral I.
- 10: ABSERR -- DOUBLE PRECISION Output
 On exit: an estimate of the modulus of the absolute error, which should be an upper bound for |I-RESULT|.
- 11: W(LW) -- DOUBLE PRECISION array Output
 On exit: details of the computation, as described in Section 8.
- 12: LW -- INTEGER Input
 On entry:
 the dimension of the array W as declared in the (sub)program from which D01APF is called.
 The value of LW (together with that of LIW below) imposes a bound on the number of sub-intervals into which the interval of integration may be divided by the routine. The number of sub-intervals cannot exceed LW/4. The more difficult the integrand, the larger LW should be. Suggested value: LW = 800 to 2000 is adequate for most problems. Constraint: LW >= 8.
- 13: IW(LIW) -- INTEGER array Output
 On exit: IW(1) contains the actual number of sub-intervals used. The rest of the array is used as workspace.
- 14: LIW -- INTEGER Input

On entry:
 the dimension of the array IW as declared in the
 (sub)program from which D01APF is called.
 The number of sub-intervals into which the interval of
 integration may be divided cannot exceed LIW. Suggested
 value: $LIW = LW/4$. Constraint: $LIW \geq 2$.

15: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. Users who are
 unfamiliar with this parameter should refer to the Essential
 Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or
 gives a warning (see Section 6).

For this routine, because the values of output parameters
 may be useful even if IFAIL \neq 0 on exit, users are
 recommended to set IFAIL to -1 before entry. It is then
 essential to test the value of IFAIL on exit.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
 output on the current error message unit (as defined by X04AAF).

IFAIL= 1

The maximum number of subdivisions allowed with the given
 workspace has been reached without the accuracy requirements
 being achieved. Look at the integrand in order to determine
 the integration difficulties. If the position of a
 discontinuity or a singularity of algebraico-logarithmic
 type within the interval can be determined, the interval
 must be split up at this point and the integrator called on
 the subranges. If necessary, another integrator, which is
 designed for handling the difficulty involved, must be used.
 Alternatively consider relaxing the accuracy requirements
 specified by EPSABS and EPSREL, or increasing the amount of
 workspace.

IFAIL= 2

Round-off error prevents the requested tolerance from being
 achieved. Consider requesting less accuracy.

IFAIL= 3

Extremely bad local integrand behaviour causes a very strong subdivision around one (or more) points of the interval.
The same advice applies as in the case of IFAIL = 1.

IFAIL= 4

On entry $B \leq A$,

or $ALFA \leq -1$,

or $BETA \leq -1$,

or $KEY < 1$,

or $KEY > 4$.

IFAIL= 5

On entry $LW < 8$,

or $LIW < 2$.

7. Accuracy

The routine cannot guarantee, but in practice usually achieves, the following accuracy:

$$|I-RESULT| \leq tol,$$

where

$$tol = \max\{|EPSABS|, |EPSREL| * |I|\},$$

and EPSABS and EPSREL are user-specified absolute and relative error tolerances.

Moreover it returns the quantity ABSERR which, in normal circumstances, satisfies:

$$|I-RESULT| \leq ABSERR \leq tol.$$

8. Further Comments

The time taken by the routine depends on the integrand and on the accuracy required.

If IFAIL \neq 0 on exit, then the user may wish to examine the contents of the array W, which contains the end-points of the

sub-intervals used by D01APF along with the integral contributions and error estimates over these sub-intervals.

Specifically, for $i=1,2,\dots,n$, let r_i denote the approximation to the value of the integral over the sub-interval $[a_i, b_i]$ in the partition of $[a,b]$ and e_i be the corresponding absolute error

estimate. Then, $\int_a^b f(x)w(x)dx \approx r_i$ and $RESULT = \sum_{i=1}^n r_i$. The value of n is returned in $IW(1)$, and the values a_i, b_i, e_i and r_i are

stored consecutively in the array W , that is:

```

a_i = W(i),
b_i = W(n+i),
e_i = W(2n+i),
r_i = W(3n+i).

```

9. Example

To compute:

$$\int_0^1 \ln(x) \cos(10(\pi)x) dx \quad \text{and}$$

$$\int \frac{1}{\sin(10x)} dx.$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

D01AQF(3NAG) Foundation Library (12/10/92) D01AQF(3NAG)

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

for user-specified values of a , b and c .

```

SUBROUTINE D01AQF (G, A, B, C, EPSABS, EPSREL, RESULT,
1             ABSERR, W, LW, IW, LIW, IFAIL)
  INTEGER      LW, IW(IW), LIW, IFAIL
  DOUBLE PRECISION G, A, B, C, EPSABS, EPSREL, RESULT,
1             ABSERR, W(LW)
  EXTERNAL     G

```

DO1AQF is based upon the QUADPACK routine QAWC (Piessens et al [3]) and integrates a function of the form $g(x)w(x)$, where the weight function

$$w(x) = \frac{1}{x-c}$$

is that of the Hilbert transform. (If $a < c < b$ the integral has to be interpreted in the sense of a Cauchy principal value.) It is an adaptive routine which employs a 'global' acceptance criterion (as defined by Malcolm and Simpson [1]). Special care is taken to ensure that c is never the end-point of a sub-interval (Piessens et al [2]). On each sub-interval (c_1, c_2) modified Clenshaw-Curtis

integration of orders 12 and 24 is performed if $c_2 - d \leq c \leq c_1 + d$

where $d = (c_2 - c_1)/20$. Otherwise the Gauss 7-point and Kronrod 15-point rules are used. The local error estimation is described by

Piessens et al [3].

5. Parameters

- 1: G -- DOUBLE PRECISION FUNCTION, supplied by the user.
External Procedure
 G must return the value of the function g at a given point.

Its specification is:

```
DOUBLE PRECISION FUNCTION G (X)
DOUBLE PRECISION X
```

- 1: X -- DOUBLE PRECISION Input
 On entry: the point at which the function g must be evaluated.

G must be declared as EXTERNAL in the (sub)program from which D01AQF is called. Parameters denoted as Input must not be changed by this procedure.

- 2: A -- DOUBLE PRECISION Input
On entry: the lower limit of integration, a.

- 3: B -- DOUBLE PRECISION Input
On entry: the upper limit of integration, b. It is not necessary that $a < b$.

- 4: C -- DOUBLE PRECISION Input
On entry: the parameter c in the weight function.
Constraint: C must not equal A or B.

- 5: EPSABS -- DOUBLE PRECISION Input
On entry: the absolute accuracy required. If EPSABS is negative, the absolute value is used. See Section 7.

- 6: EPSREL -- DOUBLE PRECISION Input
On entry: the relative accuracy required. If EPSREL is negative, the absolute value is used. See Section 7.

- 7: RESULT -- DOUBLE PRECISION Output
On exit: the approximation to the integral I.

- 8: ABSERR -- DOUBLE PRECISION Output
On exit: an estimate of the modulus of the absolute error, which should be an upper bound for $|I - \text{RESULT}|$.

- 9: W(LW) -- DOUBLE PRECISION array Output
On exit: details of the computation, as described in Section 8.

- 10: LW -- INTEGER Input
On entry:
the dimension of the array W as declared in the (sub)program from which D01AQF is called.
The value of LW (together with that of LIW below) imposes a bound on the number of sub-intervals into which the interval of integration may be divided by the routine. The number of sub-intervals cannot exceed $LW/4$. The more difficult the integrand, the larger LW should be. Suggested value: $LW = 800$ to 2000 is adequate for most problems. Constraint: $LW \geq 4$.

11: IW(LIW) -- INTEGER array Output
 On exit: IW(1) contains the actual number of sub-intervals used. The rest of the array is used as workspace.

12: LIW -- INTEGER Input
 On entry:
 the dimension of the array IW as declared in the (sub)program from which D01AQF is called.
 The number of sub-intervals into which the interval of integration may be divided cannot exceed LIW. Suggested value: $LIW = LW/4$. Constraint: $LIW \geq 1$.

13: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL \neq 0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

The maximum number of subdivisions allowed with the given workspace has been reached without the accuracy requirements being achieved. Look at the integrand in order to determine the integration difficulties. Another integrator which is designed for handling the type of difficulty involved, must be used. Alternatively consider relaxing the accuracy requirements specified by EPSABS and EPSREL, or increasing the workspace.

IFAIL= 2

Round-off error prevents the requested tolerance from being achieved. Consider requesting less accuracy.

IFAIL= 3

Extremely bad local behaviour of $g(x)$ causes a very strong subdivision around one (or more) points of the interval. The same advice applies as in the case of IFAIL = 1.

IFAIL= 4

On entry $C = A$ or $C = B$.

IFAIL= 5

On entry $LW < 4$,

or $LIW < 1$.

7. Accuracy

The routine cannot guarantee, but in practice usually achieves, the following accuracy:

$$|I-RESULT| \leq \text{tol},$$

where

$$\text{tol} = \max\{|\text{EPSABS}|, |\text{EPSREL}| * |I|\},$$

and EPSABS and EPSREL are user-specified absolute and relative error tolerances. Moreover it returns the quantity ABSERR which, in normal circumstances satisfies:

$$|I-RESULT| \leq \text{ABSERR} \leq \text{tol}.$$

8. Further Comments

The time taken by the routine depends on the integrand and on the accuracy required.

If IFAIL \neq 0 on exit, then the user may wish to examine the contents of the array W, which contains the end-points of the sub-intervals used by D01AQF along with the integral contributions and error estimates over these sub-intervals.

Specifically, for $i=1,2,\dots,n$, let r_i denote the approximation to the value of the integral over the sub-interval $[a_i, b_i]$ in the partition of $[a,b]$ and e_i be the corresponding absolute error

$$\frac{1}{n} \int_a^b g(x)w(x)dx \approx r$$
 estimate. Then, $\frac{1}{n} \int_a^b g(x)w(x)dx \approx r$ and $RESULT = \frac{1}{n} \int_a^b g(x)w(x)dx$. The value of n is returned in $IW(1)$, and the values a , b , e and r are stored consecutively in the array W , that is:

```

a = W(i),
b = W(n+i),
e = W(2n+i) and
r = W(3n+i).

```

9. Example

To compute the Cauchy principal value of

$$\frac{1}{\int_{-1}^1 \frac{dx}{(x+0.01)^2(x-\frac{1}{2})^2}}.$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

D01ASF(3NAG) Foundation Library (12/10/92) D01ASF(3NAG)

D01 -- Quadrature D01ASF
 D01ASF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for

your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D01ASF calculates an approximation to the sine or the cosine transform of a function g over $[a, \infty)$:

$$I = \frac{\int_a^{\infty} g(x) \sin((\omega)x) dx}{\int_a^{\infty} g(x) \cos((\omega)x) dx} \quad \text{or} \quad I = \frac{\int_a^{\infty} g(x) \cos((\omega)x) dx}{\int_a^{\infty} g(x) \sin((\omega)x) dx}$$

(for a user-specified value of (ω)).

2. Specification

```

SUBROUTINE D01ASF (G, A, OMEGA, KEY, EPSABS, RESULT,
1                ABSERR, LIMLST, LST, ERLST, RSLST,
2                IERLST, W, LW, IW, LIW, IFAIL)
  INTEGER          KEY, LIMLST, LST, IERLST(LIMLST), LW, IW
1                (LIW), LIW, IFAIL
  DOUBLE PRECISION G, A, OMEGA, EPSABS, RESULT, ABSERR, ERLST
1                (LIMLST), RSLST(LIMLST), W(LW)
  EXTERNAL          G
```

3. Description

D01ASF is based upon the QUADPACK routine QAWFE (Piessens et al [2]). It is an adaptive routine, designed to integrate a function of the form $g(x)w(x)$ over a semi-infinite interval, where $w(x)$ is either $\sin((\omega)x)$ or $\cos((\omega)x)$. Over successive intervals

$$C_k = [a + (k-1)c, a + kc], \quad k=1, 2, \dots, LST$$

integration is performed by the same algorithm as is used by D01ANF. The intervals C_k are of constant length

$$k$$

$$c = \{2[|(\omega)|] + 1\}(\pi) / |(\omega)|, \quad (\omega) \neq 0$$

where $[|(\omega)|]$ represents the largest integer less than or equal to $|(\omega)|$. Since c equals an odd number of half periods, the integral contributions over succeeding intervals will alternate in sign when the function g is positive and monotonically decreasing over $[a, \infty)$. The algorithm, described by [2], incorporates a global acceptance criterion (as defined by Malcolm and Simpson [1]) together with the (epsilon)-algorithm (Wynn [3]) to perform extrapolation. The local error estimation is described by Piessens et al [2].

If $(\omega) = 0$ and $KEY = 1$, the routine uses the same algorithm as D01AMF (with $EPSREL = 0.0$).

In contrast to the other routines in Chapter D01, D01ASF works only with a user-specified absolute error tolerance (EPSABS). Over the interval C it attempts to satisfy the absolute accuracy

$$k$$

requirement

$$EPSA_k = U_k * EPSABS_k$$

$$k-1$$

where $U_k = (1-p)p^{k-1}$, for $k=1, 2, \dots$ and $p=0.9$.

However, when difficulties occur during the integration over the k th sub-interval C_k such that the error flag $IERLST(k)$ is non-

$$k$$

zero, the accuracy requirement over subsequent intervals is relaxed. See Piessens et al [2] for more details.

5. Parameters

- 1: G -- DOUBLE PRECISION FUNCTION, supplied by the user.
External Procedure
 G must return the value of the function g at a given point.

Its specification is:

DOUBLE PRECISION FUNCTION G (X)
 DOUBLE PRECISION X

- 1: X -- DOUBLE PRECISION Input
 On entry: the point at which the function g must be evaluated.
 G must be declared as EXTERNAL in the (sub)program from which D01ASF is called. Parameters denoted as Input must not be changed by this procedure.
- 2: A -- DOUBLE PRECISION Input
 On entry: the lower limit of integration, a .
- 3: OMEGA -- DOUBLE PRECISION Input
 On entry: the parameter (ω) in the weight function of the transform.
- 4: KEY -- INTEGER Input
 On entry: indicates which integral is to be computed:
 if KEY = 1, $w(x)=\cos((\omega)x)$;
 if KEY = 2, $w(x)=\sin((\omega)x)$.
 Constraint: KEY = 1 or 2.
- 5: EPSABS -- DOUBLE PRECISION Input
 On entry: the absolute accuracy requirement. If EPSABS is negative, the absolute value is used. See Section 7.
- 6: RESULT -- DOUBLE PRECISION Output
 On exit: the approximation to the integral I .
- 7: ABSERR -- DOUBLE PRECISION Output
 On exit: an estimate of the modulus of the absolute error, which should be an upper bound for $|I-RESULT|$.
- 8: LIMLST -- INTEGER Input

- On entry: an upper bound on the number of intervals C_k needed for the integration. Suggested value: $LIMLST = 50$ is adequate for most problems. Constraint: $LIMLST \geq 3$.
- 9: LST -- INTEGER Output
 On exit: the number of intervals C_k actually used for the integration.
- 10: ERLST(LIMLST) -- DOUBLE PRECISION array Output
 On exit: ERLST(k) contains the error estimate corresponding to the integral contribution over the interval C_k , for $k=1,2,\dots,LST$.
- 11: RSLST(LIMLST) -- DOUBLE PRECISION array Output
 On exit: RSLST(k) contains the integral contribution over the interval C_k for $k=1,2,\dots,LST$.
- 12: IERLST(LIMLST) -- INTEGER array Output
 On exit: IERLST(k) contains the error flag corresponding to RSLST(k), for $k=1,2,\dots,LST$. See Section 6.
- 13: W(LW) -- DOUBLE PRECISION array Workspace
- 14: LW -- INTEGER Input
 On entry:
 the dimension of the array W as declared in the (sub)program from which D01ASF is called.
 The value of LW (together with that of LIW below) imposes a bound on the number of sub-intervals into which each interval C_k may be divided by the routine. The number of sub-intervals cannot exceed $LW/4$. The more difficult the integrand, the larger LW should be. Suggested value: a value in the range 800 to 2000 is adequate for most problems. Constraint: $LW \geq 4$.
- 15: IW(LIW) -- INTEGER array Output
 On exit: IW(1) contains the maximum number of sub-intervals actually used for integrating over any of the intervals C_k .
 The rest of the array is used as workspace.

16: LIW -- INTEGER Input
 On entry:
 the dimension of the array IW as declared in the
 (sub)program from which D01ASF is called.
 The number of sub-intervals into which each interval C_k may
 be divided cannot exceed $LIW/2$. Suggested value: $LIW = LW/2$.
 Constraint: $LIW \geq 2$.

17: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. Users who are
 unfamiliar with this parameter should refer to the Essential
 Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or
 gives a warning (see Section 6).

For this routine, because the values of output parameters
 may be useful even if IFAIL \neq 0 on exit, users are
 recommended to set IFAIL to -1 before entry. It is then
 essential to test the value of IFAIL on exit.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
 output on the current error message unit (as defined by X04AAF).

IFAIL= 1

The maximum number of subdivisions allowed with the given
 workspace has been reached without the accuracy requirements
 being achieved. Look at the integrand in order to determine
 the integration difficulties. If the position of a local
 difficulty within the interval can be determined (e.g. a
 singularity of the integrand or its derivative, a peak, a
 discontinuity, etc) you will probably gain from splitting up
 the interval at this point and calling D01ASF on the
 infinite subrange and an appropriate integrator on the
 finite subrange. Alternatively, consider relaxing the
 accuracy requirements specified by EPSABS or increasing the
 amount of workspace.

IFAIL= 2

Round-off error prevents the requested tolerance from being
 achieved. The error may be underestimated. Consider

requesting less accuracy.

IFAIL= 3

Extremely bad local integrand behaviour causes a very strong subdivision around one (or more) points of the interval. The same advice applies as in the case of IFAIL = 1.

IFAIL= 4

The requested tolerance cannot be achieved, because the extrapolation does not increase the accuracy satisfactorily; the returned result is the best which can be obtained. The same advice applies as in the case of IFAIL = 1.

IFAIL= 5

The integral is probably divergent, or slowly convergent. Please note that divergence can occur with any non-zero value of IFAIL.

IFAIL= 6

On entry KEY < 1,

or KEY > 2,

or LIMLST < 3.

IFAIL= 7

Bad integration behaviour occurs within one or more of the intervals C_k . Location and type of the difficulty involved can be determined from the vector IERLST (see below).

IFAIL= 8

Maximum number of intervals C_k (= LIMLST) allowed has been achieved. Increase the value of LIMLST to allow more cycles.

IFAIL= 9

The extrapolation table constructed for convergence acceleration of the series formed by the integral contribution over the intervals C_k , does not converge to the required accuracy.

IFAIL= 10

On entry LW < 4,

or $LIW < 2$.

In the cases $IFAIL = 7, 8$ or 9 , additional information about the cause of the error can be obtained from the array `IERLST`, as follows:

`IERLST(k)=1`

The maximum number of subdivisions = $\min(LW/4, LIW/2)$ has been achieved on the k th interval.

`IERLST(k)=2`

Occurrence of round-off error is detected and prevents the tolerance imposed on the k th interval from being achieved.

`IERLST(k)=3`

Extremely bad integrand behaviour occurs at some points of the k th interval.

`IERLST(k)=4`

The integration procedure over the k th interval does not converge (to within the required accuracy) due to round-off in the extrapolation procedure invoked on this interval. It is assumed that the result on this interval is the best which can be obtained.

`IERLST(k)=5`

The integral over the k th interval is probably divergent or slowly convergent. It must be noted that divergence can occur with any other value of `IERLST(k)`.

7. Accuracy

The routine cannot guarantee, but in practice usually achieves, the following accuracy:

$$|I-RESULT| \leq |EPSABS|,$$

where `EPSABS` is the user-specified absolute error tolerance. Moreover, it returns the quantity `ABSERR`, which, in normal circumstances, satisfies

$$|I-RESULT| \leq ABSERR \leq |EPSABS|.$$

8. Further Comments

None.

9. Example

To compute

$$\int_0^{\infty} \frac{1}{\sqrt{x}} \cos\left(\frac{\pi x}{2}\right) dx.$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

D01 -- Quadrature

D01BBF

D01BBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

Note for users via the AXIOM system: the interface to this routine has been enhanced for use with AXIOM and is slightly different to that offered in the standard version of the Foundation Library.

1. Purpose

D01BBF returns the weights and abscissae appropriate to a Gaussian quadrature formula with a specified number of abscissae. The formulae provided are Gauss-Legendre, Gauss-Rational, Gauss-Laguerre and Gauss-Hermite.

2. Specification

```

SUBROUTINE D01BBF (A, B, ITYPE, N, WEIGHT, ABSCIS, GTYPE,
1                IFAIL)
  INTEGER          ITYPE, N, GTYPE, IFAIL
  DOUBLE PRECISION A, B, WEIGHT(N), ABSCIS(N)

```

3. Description

This routine returns the weights and abscissae for use in the Gaussian quadrature of a function $f(x)$. The quadrature takes the form

$$S = \sum_{i=1}^n w_i f(x_i)$$

where w_i are the weights and x_i are the abscissae (see Davis and Rabinowitz [1], Froberg [2], Ralston [3] or Stroud and Secrest [4]).

Weights and abscissae are available for Gauss-Legendre, Gauss-Rational, Gauss-Laguerre and Gauss-Hermite quadrature, and for a selection of values of n (see Section 5).

(a) Gauss-Legendre Quadrature:

$$\tilde{S} = \int_a^b f(x) dx$$

where a and b are finite and it will be exact for any function of the form

$$f(x) = \sum_{i=0}^{2n-1} c_i x^i$$

(b) Gauss-Rational quadrature:

$$\tilde{S} = \int_a^{\infty} f(x) dx \quad (a+b>0) \quad \text{or} \quad \tilde{S} = \int_{-\infty}^a f(x) dx \quad (a+b<0)$$

and will be exact for any function of the form

$$\sum_{i=0}^{2n-1} c_i (x+b)^i$$

$$f(x) = \sum_{i=2}^{\infty} \frac{(-1)^i}{(x+b)^{2i+1}} = \sum_{i=0}^{\infty} \frac{(-1)^{i+1}}{(x+b)^{2i+3}}$$

- (c) Gauss-Laguerre quadrature, adjusted weights option:

$$\tilde{S} = \frac{\int_a^{\infty} f(x) dx}{\int_a^{\infty} e^{-bx} dx} \quad (b > 0) \quad \text{or} \quad \tilde{S} = \frac{\int_{-\infty}^a f(x) dx}{\int_{-\infty}^a e^{-bx} dx} \quad (b < 0)$$

and will be exact for any function of the form

$$f(x) = e^{-bx} \sum_{i=0}^{2n-1} c_i x^i$$

- (d) Gauss-Hermite quadrature, adjusted weights option:

$$\tilde{S} = \frac{\int_{-\infty}^{\infty} f(x) dx}{\int_{-\infty}^{\infty} e^{-x^2} dx}$$

and will be exact for any function of the form

$$f(x) = e^{-b(x-a)^2} \sum_{i=0}^{2n-1} c_i x^i \quad (b > 0)$$

- (e) Gauss-Laguerre quadrature, normal weights option:

$$\tilde{S} = \frac{\int_a^{\infty} e^{-bx} f(x) dx}{\int_a^{\infty} e^{-bx} dx} \quad (b > 0) \quad \text{or} \quad \tilde{S} = \frac{\int_{-\infty}^a e^{-bx} f(x) dx}{\int_{-\infty}^a e^{-bx} dx}$$

(b < 0)

and will be exact for any function of the form

$$\sum_{i=0}^{2n-1} c_i x^i$$

$$f(x) = \sum_{i=0}^n c_i x^i$$

(f) Gauss-Hermite quadrature, normal weights option:

$$S \sim \int_{-\infty}^{+\infty} \frac{e^{-b(x-a)^2}}{e^{-b(x-a)^2}} f(x) dx$$

and will be exact for any function of the form:

$$f(x) = \sum_{i=0}^{2n-1} c_i x^i$$

Note: that the Gauss-Legendre abscissae, with $a=-1$, $b=+1$, are the zeros of the Legendre polynomials; the Gauss-Laguerre abscissae, with $a=0$, $b=1$, are the zeros of the Laguerre polynomials; and the Gauss-Hermite abscissae, with $a=0$, $b=1$, are the zeros of the Hermite polynomials.

5. Parameters

- 1: A -- DOUBLE PRECISION Input
 - 2: B -- DOUBLE PRECISION Input
- On entry: the quantities a and b as described in the appropriate subsection of Section 3.

- 3: ITYPE -- INTEGER Input
 On entry: indicates the type of weights for Gauss-Laguerre or Gauss-Hermite quadrature (see Section 3):
- if ITYPE = 1, adjusted weights will be returned;
- if ITYPE = 0, normal weights will be returned.
- Constraint: ITYPE = 0 or 1.
- For Gauss-Legendre or Gauss-Rational quadrature, this parameter is not used.
- 4: N -- INTEGER Input
 On entry: the number of weights and abscissae to be returned, n. Constraint: N = 1,2,3,4,5,6,8,10,12,14,16,20,24,32,48 or 64.
- 5: WEIGHT(N) -- DOUBLE PRECISION array Output
 On exit: the N weights. For Gauss-Laguerre and Gauss-Hermite quadrature, these will be the adjusted weights if ITYPE = 1, and the normal weights if ITYPE = 0.
- 6: ABCIS(N) -- DOUBLE PRECISION array Output
 On exit: the N abscissae.
- 7: GTYPE -- INTEGER Input
 On entry: The value of GTYPE indicates which quadrature formula are to be used:
- GTYPE = 0 for Gauss-Legendre weights and abscissae;
- GTYPE = 1 for Gauss-Rational weights and abscissae;
- GTYPE = 2 for Gauss-Laguerre weights and abscissae;
- GTYPE = 3 for Gauss-Hermite weights and abscissae.
- 8: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

The N-point rule is not among those stored. If the soft fail option is used, the weights and abscissae returned will be those for the largest valid value of N less than the requested value, and the excess elements of WEIGHT and ABSCIS (i.e., up to the requested N) will be filled with zeros.

IFAIL= 2

The value of A and/or B is invalid.

Gauss-Rational: $A + B = 0$

Gauss-Laguerre: $B = 0$

Gauss-Hermite: $B \leq 0$

If the soft fail option is used the weights and abscissae are returned as zero.

IFAIL= 3

Laguerre and Hermite normal weights only: underflow is occurring in evaluating one or more of the normal weights. If the soft fail option is used, the underflowing weights are returned as zero. A smaller value of N must be used; or adjusted weights should be used (ITYPE = 1). In the latter case, take care that underflow does not occur when evaluating the integrand appropriate for adjusted weights.

IFAIL=4

GTYP < 0 or GTYP > 3

7. Accuracy

The weights and abscissae are stored for standard values of A and B to full machine accuracy.

8. Further Comments

Timing is negligible.

9. Example

This example program returns the abscissae and (adjusted) weights

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

[illegible]

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

DO1FCF attempts to evaluate a multi-dimensional integral (up to 15 dimensions), with constant and finite limits, to a specified relative accuracy, using an adaptive subdivision strategy.

```

SUBROUTINE DO1FCF (NDIM, A, B, MINPTS, MAXPTS, FUNCTN,
1              EPS, ACC, LENWRK, WRKSTR, FINVAL, IFAIL)
  INTEGER      NDIM, MINPTS, MAXPTS, LENWRK, IFAIL
  DOUBLE PRECISION A(NDIM), B(NDIM), FUNCTN, EPS, ACC, WRKSTR
1              (LENWRK), FINVAL
  EXTERNAL     FUNCTN

```

The routine returns an estimate of a multi-dimensional integral over a hyper-rectangle (i.e., with constant limits), and also an estimate of the relative error. The user sets the relative accuracy required, supplies the integrand as a function subprogram (FUNCTN), and also sets the minimum and maximum acceptable number of calls to FUNCTN (in MINPTS and MAXPTS).

The routine operates by repeated subdivision of the hyper-rectangular region into smaller hyper-rectangles. In each subregion, the integral is estimated using a seventh-degree rule, and an error estimate is obtained by comparison with a fifth-

degree rule which uses a subset of the same points. The fourth differences of the integrand along each co-ordinate axis are evaluated, and the subregion is marked for possible future subdivision in half along that co-ordinate axis which has the largest absolute fourth difference.

If the estimated errors, totalled over the subregions, exceed the requested relative error (or if fewer than MINPTS calls to FUNCTN have been made), further subdivision is necessary, and is performed on the subregion with the largest estimated error, that subregion being halved along the appropriate co-ordinate axis.

The routine will fail if the requested relative error level has not been attained by the time MAXPTS calls to FUNCTN have been made; or, if the amount LENWRK of working storage is insufficient. A formula for the recommended value of LENWRK is given in Section 5. If a smaller value is used, and is exhausted in the course of execution, the routine switches to a less efficient mode of operation; only if this mode also breaks down is insufficient storage reported.

D01FCF is based on the HALF subroutine developed by van Dooren and de Ridder [1]. It uses a different basic rule, described by Genz and Malik [2].

- [2] Genz A C and Malik A A (1980) An Adaptive Algorithm for Numerical Integration over an N-dimensional Rectangular Region. J. Comput. Appl. Math. 6 295--302.

5. Parameters

- 1: NDIM -- INTEGER Input
 On entry: the number of dimensions of the integral, n.
 Constraint: $2 \leq \text{NDIM} \leq 15$.
- 2: A(NDIM) -- DOUBLE PRECISION array Input
 On entry: the lower limits of integration, a_i, for
 i=1,2,...,n.

3: B(NDIM) -- DOUBLE PRECISION array Input
 On entry: the upper limits of integration, b_i , for
 $i=1,2,\dots,n$.

4: MINPTS -- INTEGER Input/Output
 On entry: MINPTS must be set to the minimum number of
 integrand evaluations to be allowed. On exit: MINPTS
 contains the actual number of integrand evaluations used by
 D01FCF.

5: MAXPTS -- INTEGER Input
 On entry: the maximum number of integrand evaluations to be
 allowed.
 Constraints:
 $MAXPTS \geq MINPTS$

$MAXPTS \geq (\alpha),$

where $(\alpha) = 2^{NDIM+1} + 2 \cdot NDIM$

6: FUNCTN -- DOUBLE PRECISION FUNCTION, supplied by the
 user.

External Procedure

FUNCTN must return the value of the integrand f at a given
 point.

Its specification is:

```
DOUBLE PRECISION FUNCTION FUNCTN (NDIM,Z)
INTEGER          NDIM
DOUBLE PRECISION Z(NDIM)
```

1: NDIM -- INTEGER Input
 On entry: the number of dimensions of the integral, n .

2: Z(NDIM) -- DOUBLE PRECISION array Input
 On entry: the co-ordinates of the point at which the
 integrand must be evaluated.

FUNCTN must be declared as EXTERNAL in the (sub)program
 from which D01FCF is called. Parameters denoted as
 Input must not be changed by this procedure.

7: EPS -- DOUBLE PRECISION Input
 On entry: the relative error acceptable to the user. When

the solution is zero or very small relative accuracy may not be achievable but the user may still set EPS to a reasonable value and check for the error exit IFAIL = 2. Constraint: EPS > 0.0.

8: ACC -- DOUBLE PRECISION Output
On exit: the estimated relative error in FINVAL.

9: LENWRK -- INTEGER Input
On entry:
the dimension of the array WRKSTR as declared in the (sub)program from which D01FCF is called.
Suggested value: for maximum efficiency, LENWRK >= (NDIM+2)*(1+MAXPTS/(alpha)) (see parameter MAXPTS for (alpha)).

If LENWRK is less than this, the routine will usually run less efficiently and may fail. Constraint: LENWRK >= 2*NDIM+4.

10: WRKSTR(LENWRK) -- DOUBLE PRECISION array Workspace

11: FINVAL -- DOUBLE PRECISION Output
On exit: the best estimate obtained for the integral.

12: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.
On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL /= 0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit. To suppress the output of an error message when soft failure occurs, set IFAIL to 1.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

IFAIL= 1
On entry NDIM < 2,
or NDIM > 15,

or MAXPTS is too small,

or LENWRK<2*NDIM+4,

or EPS <= 0.0.

IFAIL= 2

MAXPTS was too small to obtain the required relative accuracy EPS. On soft failure, FINVAL and ACC contain estimates of the integral and the relative error, but ACC will be greater than EPS.

IFAIL= 3

LENWRK was too small. On soft failure, FINVAL and ACC contain estimates of the integral and the relative error, but ACC will be greater than EPS.

7. Accuracy

A relative error estimate is output through the parameter ACC.

8. Further Comments

Execution time will usually be dominated by the time taken to evaluate the integrand FUNCTN, and hence the maximum time that could be taken will be proportional to MAXPTS.

9. Example

This example program estimates the integral

$$\frac{\int_0^1 \int_0^1 \int_0^1 \int_0^1 \frac{4z^2 \exp(2z^2)}{(1+z^2)^4} dz dz dz dz}{1} = 0.575364.$$

The accuracy requested is one part in 10,000.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

D01GAF(3NAG)

Foundation Library (12/10/92)

D01GAF(3NAG)

D01 -- Quadrature

D01GAF

D01GAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D01GAF integrates a function which is specified numerically at four or more points, over the whole of its specified range, using third-order finite-difference formulae with error estimates, according to a method due to Gill and Miller.

2. Specification

```
SUBROUTINE D01GAF (X, Y, N, ANS, ER, IFAIL)
  INTEGER          N, IFAIL
  DOUBLE PRECISION X(N), Y(N), ANS, ER
```

3. Description

This routine evaluates the definite integral

$$I = \int_{x_1}^{x_n} y(x) dx,$$

where the function y is specified at the n -points x_1, x_2, \dots, x_n ,

which should be all distinct, and in either ascending or descending order. The integral between successive points is calculated by a four-point finite-difference formula centred on the interval concerned, except in the case of the first and last intervals, where four-point forward and backward difference formulae respectively are employed. If n is less than 4, the routine fails. An approximation to the truncation error is

integrated and added to the result. It is also returned separately to give an estimate of the uncertainty in the result. The method is due to Gill and Miller.

4. References

- [1] Gill P E and Miller G F (1972) An Algorithm for the Integration of Unequally Spaced Data. Comput. J. 15 80--83.

5. Parameters

- 1: X(N) -- DOUBLE PRECISION array Input
 On entry: the values of the independent variable, i.e., the x_1, x_2, \dots, x_n . Constraint: either $X(1) < X(2) < \dots < X(N)$ or $X(1) > X(2) > \dots > X(N)$.
- 2: Y(N) -- DOUBLE PRECISION array Input
 On entry: the values of the dependent variable y_i at the points x_i , for $i=1,2,\dots,n$.
- 3: N -- INTEGER Input
 On entry: the number of points, n. Constraint: $N \geq 4$.
- 4: ANS -- DOUBLE PRECISION Output
 On exit: the estimate of the integral.
- 5: ER -- DOUBLE PRECISION Output
 On exit: an estimate of the uncertainty in ANS.
- 6: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

Indicates that fewer than four-points have been supplied to

the routine.

IFAIL= 2

Values of X are neither strictly increasing nor strictly decreasing.

IFAIL= 3

Two points have the same X-value.

No error is reported arising from the relative magnitudes of ANS and ER on return, due to the difficulty when the true answer is zero.

7. Accuracy

No accuracy level is specified by the user before calling the routine but on return $\text{ABS}(\text{ER})$ is an approximation to, but not necessarily a bound for, $|\text{I}-\text{ANS}|$. If on exit $\text{IFAIL} > 0$, both ANS and ER are returned as zero.

8. Further Comments

The time taken by the routine depends on the number of points supplied, n.

In their paper, Gill and Miller [1] do not add the quantity ER to ANS before return. However, extensive tests have shown that a dramatic reduction in the error often results from such addition. In other cases, it does not make an improvement, but these tend to be cases of low accuracy in which the modified answer is not significantly inferior to the unmodified one. The user has the option of recovering the Gill-Miller answer by subtracting ER from ANS on return from the routine.

9. Example

The example program evaluates the integral

$$\int_0^1 \frac{dx}{1+x^2} = \frac{\pi}{4}$$

reading in the function values at 21 unequally-spaced points.

%%%%%%%%%%%%%%

$$\int_{a_1}^{b_1} \int_{a_2}^{b_2} \dots \int_{a_n}^{b_n} f(x_1, x_2, \dots, x_n) dx_1 dx_2 \dots dx_n.$$

Upon entry, unless LENWRK has been set to the minimum value $10 \times \text{NDIM}$, the routine subdivides the integration region into a number of equal volume subregions. Inside each subregion the integral and the variance are estimated by means of pseudo-random sampling. All contributions are added together to produce an estimate for the whole integral and total variance. The variance along each co-ordinate axis is determined and the routine uses this information to increase the density and change the widths of the sub-intervals along each axis, so as to reduce the total variance. The total number of subregions is then increased by a factor of two and the program recycles for another iteration. The program stops when a desired accuracy has been reached or too many integral evaluations are needed for the next cycle.

4. References

- [1] Lautrup B (1971) An Adaptive Multi-dimensional Integration Procedure. Proc. 2nd Coll. on Advanced Methods in Theoretical Physics, Marseille.

5. Parameters

- 1: NDIM -- INTEGER Input
On entry: the number of dimensions of the integral, n.
Constraint: NDIM \geq 1.

- 2: A(NDIM) -- DOUBLE PRECISION array Input
On entry: the lower limits of integration, a_i, for
i=1,2,...,n.

- 3: B(NDIM) -- DOUBLE PRECISION array Input
On entry: the upper limits of integration, b_i, for
i=1,2,...,n.

- 4: MINCLS -- INTEGER Input/Output
On entry: MINCLS must be set:

either to the minimum number of integrand evaluations to be allowed, in which case MINCLS \geq 0;

or to a negative value. In this case the routine assumes that a previous call had been made with the same parameters NDIM, A and B and with either the same integrand (in which case D01GBF continues calculation) or a similar integrand

(in which case D01GBF begins the calculation with the subdivision used in the last iteration of the previous call) . See also WRKSTR. On exit: MINCLS contains the number of integrand evaluations actually used by D01GBF.

- 5: MAXCLS -- INTEGER Input
 On entry: the maximum number of integrand evaluations to be allowed. In the continuation case this is the number of new integrand evaluations to be allowed. These counts do not include zero integrand values.

Constraints:

MAXCLS > MINCLS,

MAXCLS >= 4*(NDIM+1).

- 6: FUNCTN -- DOUBLE PRECISION FUNCTION, supplied by the user. External Procedure
 FUNCTN must return the value of the integrand f at a given point.

Its specification is:

```
DOUBLE PRECISION FUNCTION FUNCTN (NDIM, X)
INTEGER          NDIM
DOUBLE PRECISION X(NDIM)
```

- 1: NDIM -- INTEGER Input
 On entry: the number of dimensions of the integral, n.

- 2: X(NDIM) -- DOUBLE PRECISION array Input
 On entry: the co-ordinates of the point at which the integrand must be evaluated.

FUNCTN must be declared as EXTERNAL in the (sub)program from which D01GBF is called. Parameters denoted as Input must not be changed by this procedure.

- 7: EPS -- DOUBLE PRECISION Input
 On entry: the relative accuracy required. Constraint: EPS >= 0.0.

- 8: ACC -- DOUBLE PRECISION Output
 On exit: the estimated relative accuracy of FINEST.

- 9: LENWRK -- INTEGER Input
 On entry:
 the dimension of the array WRKSTR as declared in the

(sub)program from which D01GBF is called.
 For maximum efficiency, LENWRK should be about

$$\frac{1}{\text{NDIM}}$$

$$3 \cdot \text{NDIM} \cdot (\text{MAXCLS}/4) + 7 \cdot \text{NDIM}.$$

If LENWRK is given the value $10 \cdot \text{NDIM}$ then the subroutine uses only one iteration of a crude Monte Carlo method with MAXCLS sample points. Constraint: $\text{LENWRK} \geq 10 \cdot \text{NDIM}$.

- 10: WRKSTR(LENWRK) -- DOUBLE PRECISION array Input/Output
 On entry: if MINCLS<0, WRKSTR must be unchanged from the previous call of D01GBF - except that for a new integrand WRKSTR(LENWRK) must be set to 0.0. See also MINCLS. On exit: WRKSTR contains information about the current sub-interval structure which could be used in later calls of D01GBF. In particular, WRKSTR(j) gives the number of sub-intervals used along the jth co-ordinate axis.
- 11: FINEST -- DOUBLE PRECISION Output
 On exit: the best estimate obtained for the integral.
- 12: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL \neq 0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit. To suppress the output of an error message when soft failure occurs, set IFAIL to 1.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

IFAIL= 1

On entry NDIM < 1,

or MINCLS \geq MAXCLS,

or LENWRK < $10 \cdot \text{NDIM}$,

or MAXCLS < 4*(NDIM+1),

or EPS < 0.0.

IFAIL= 2

MAXCLS was too small for D01GBF to obtain the required relative accuracy EPS. In this case D01GBF returns a value of FINEST with estimated relative error ACC, but ACC will be greater than EPS. This error exit may be taken before MAXCLS non-zero integrand evaluations have actually occurred, if the routine calculates that the current estimates could not be improved before MAXCLS was exceeded.

7. Accuracy

A relative error estimate is output through the parameter ACC. The confidence factor is set so that the actual error should be less than ACC 90% of the time. If a user desires a higher confidence level then a smaller value of EPS should be used.

8. Further Comments

The running time for D01GBF will usually be dominated by the time used to evaluate the integrand FUNCTN, so the maximum time that could be used is approximately proportional to MAXCLS.

For some integrands, particularly those that are poorly behaved in a small part of the integration region, D01GBF may terminate with a value of ACC which is significantly smaller than the actual relative error. This should be suspected if the returned value of MINCLS is small relative to the expected difficulty of the integral. Where this occurs, D01GBF should be called again, but with a higher entry value of MINCLS (e.g. twice the returned value) and the results compared with those from the previous call.

The exact values of FINEST and ACC on return will depend (within statistical limits) on the sequence of random numbers generated within D01GBF by calls to G05CAF. Separate runs will produce identical answers unless the part of the program executed prior to calling D01GBF also calls (directly or indirectly) routines from Chapter G05, and the series of such calls differs between runs. If desired, the user may ensure the identity or difference between runs of the results returned by D01GBF, by calling G05CBF or G05CCF respectively, immediately before calling D01GBF.

9. Example

This example program calculates the integral

$$\frac{\frac{\frac{\frac{1}{1} \cdot \frac{1}{1} \cdot \frac{1}{1} \cdot \frac{1}{1} \cdot 4x \cdot x \cdot \exp(2x \cdot x)}{1^3} \cdot \frac{1}{1^3}}{\frac{1}{1} \cdot \frac{1}{1} \cdot \frac{1}{1} \cdot \frac{1}{1}}}{\frac{1}{0} \cdot \frac{1}{0} \cdot \frac{1}{0} \cdot \frac{1}{0}} \frac{dx \cdot dx \cdot dx \cdot dx}{(1+x^2)^4} = 0.575364.$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

    ++ d01gaf(x,y,n,ifail)
    ++ integrates a function which is specified numerically at
    ++ four or more points, over the whole of its specified range, using
    ++ third-order finite-difference formulae with error estimates,
    ++ according to a method due to Gill and Miller.
    ++ See \downlink{Manual Page}{manpageXXd01gaf}.
d01gbf : (Integer,Matrix DoubleFloat,Matrix DoubleFloat,Integer,_
    DoubleFloat,Integer,Integer,Matrix DoubleFloat,Integer,Union(fn:FileName,fp:Asp4(FUN
    ++ d01gbf(ndim,a,b,maxcls,eps,lenwrk,mincls,wrkstr,ifail,functn)
    ++ returns an approximation to the integral of a function
    ++ over a hyper-rectangular region, using a Monte Carlo method. An
    ++ approximate relative error estimate is also returned. This
    ++ routine is suitable for low accuracy work.
    ++ See \downlink{Manual Page}{manpageXXd01gbf}.

E01 -- Interpolation

Introduction -- E01

Chapter E01
Interpolation

1. Scope of the Chapter

This chapter is concerned with the interpolation of a function of one or two variables. When provided with the value of the function (and possibly one or more of its lowest-order derivatives) at each of a number of values of the variable(s), the routines provide either an interpolating function or an interpolated value. For some of the interpolating functions, there are supporting routines to evaluate, differentiate or integrate them.

2. Background to the Problems

In motivation and in some of its numerical processes, this chapter has much in common with Chapter E02 (Curve and Surface Fitting). For this reason, we shall adopt the same terminology and refer to dependent variable and independent variable(s) instead of function and variable(s). Where there is only one independent variable, we shall denote it by x and the dependent variable by y . Thus, in the basic problem considered in this chapter, we are given a set of distinct values x_1, x_2, \dots, x_m of x and a corresponding set of values y_1, y_2, \dots, y_m of y , and we shall describe the problem as being one of interpolating the data points (x_r, y_r) , rather than interpolating a function. In modern usage, however, interpolation can have either of two rather different meanings, both relevant to routines in this chapter. They are

- (a) the determination of a function of x which takes the value y_r at $x = x_r$, for $r=1, 2, \dots, m$ (an interpolating function or interpolant),

(b) the determination of the value (interpolated value or interpolate) of an interpolating function at any given value, \hat{x} , say x , of x within the range of the x (so as to estimate the r value at x of the function underlying the data).

The latter is the older meaning, associated particularly with the use of mathematical tables. The term 'function underlying the data', like the other terminology described above, is used so as to cover situations additional to those in which the data points have been computed from a known function, as with a mathematical table. In some contexts, the function may be unknown, perhaps representing the dependency of one physical variable on another, say temperature upon time.

Whether the underlying function is known or unknown, the object of interpolation will usually be to approximate it to acceptable accuracy by a function which is easy to evaluate anywhere in some range of interest. Piecewise polynomials such as cubic splines (see Section 2.2 of the E02 Chapter Introduction for definitions of terms in this case), being easy to evaluate and also capable of approximating a wide variety of functions, are the types of function mostly used in this chapter as interpolating functions.

Piecewise polynomials also, to a large extent, avoid the well-known problem of large unwanted fluctuations which can arise when interpolating a data set with a simple polynomial. Fluctuations can still arise but much less frequently and much less severely than with simple polynomials. Unwanted fluctuations are avoided altogether by a routine using piecewise cubic polynomials having only first derivative continuity. It is designed especially for monotonic data, but for other data still provides an interpolant which increases, or decreases, over the same intervals as the data.

The concept of interpolation can be generalised in a number of ways. For example, we may be required to estimate the value of \hat{x}

the underlying function at a value x outside the range of the data. This is the process of extrapolation. In general, it is a good deal less accurate than interpolation and is to be avoided whenever possible.

Interpolation can also be extended to the case of two independent variables. We shall denote these by x and y , and the dependent variable by f . Methods used depend markedly on whether or not the data values of f are given at the intersections of a rectangular mesh in the (x,y) -plane. If they are, bicubic splines (see Section 2.3.2 of the E02 Chapter Introduction) are very suitable and usually very effective for the problem. For other cases, perhaps where the f values are quite arbitrarily scattered in the (x,y) -plane, polynomials and splines are not at all appropriate and special forms of interpolating function have to be employed. Many such forms have been devised and two of the most successful are in routines in this chapter. They both have continuity in first, but not higher, derivatives.

3. Recommendations on Choice and Use of Routines

3.1. General

Before undertaking interpolation, in other than the simplest cases, the user should seriously consider the alternative of using a routine from Chapter E02 to approximate the data by a polynomial or spline containing significantly fewer coefficients than the corresponding interpolating function. This approach is much less liable to produce unwanted fluctuations and so can often provide a better approximation to the function underlying the data.

When interpolation is employed to approximate either an underlying function or its values, the user will need to be satisfied that the accuracy of approximation achieved is adequate. There may be a means for doing this which is particular to the application, or the routine used may itself provide a means. In other cases, one possibility is to repeat the interpolation using one or more extra data points, if they are available, or otherwise one or more fewer, and to compare the results. Other possibilities, if it is an interpolating function which is determined, are to examine the function graphically, if that gives sufficient accuracy, or to observe the behaviour of

the differences in a finite-difference table, formed from evaluations of the interpolating function at equally-spaced values of x over the range of interest. The spacing should be small enough to cause the typical size of the differences to decrease as the order of difference increases.

3.2. One Independent Variable

E01BAF computes an interpolating cubic spline, using a particular choice for the set of knots which has proved generally satisfactory in practice. If the user wishes to choose a different set, a cubic spline routine from Chapter E02, namely E02BAF, may be used in its interpolating mode, setting NCAP7 = M+4 and all elements of the parameter W to unity. These routines provide the interpolating function in B-spline form (see Section 2.2.2 in the E02 Chapter Introduction). Routines for evaluating, differentiating and integrating this form are discussed in Section 3.7 of the E02 Chapter Introduction.

The cubic spline does not always avoid unwanted fluctuations, especially when the data show a steep slope close to a region of small slope, or when the data inadequately represent the underlying curve. In such cases, E01BEF can be very useful. It derives a piecewise cubic polynomial (with first derivative continuity) which, between any adjacent pair of data points, either increases all the way, or decreases all the way (or stays constant). It is especially suited to data which are monotonic over their whole range.

In this routine, the interpolating function is represented simply by its value and first derivative at the data points. Supporting routines compute its value and first derivative elsewhere, as well as its definite integral over an arbitrary interval.

3.3. Two Independent Variables

3.3.1. Data on a rectangular mesh

Given the value f_{qr} of the dependent variable f at the point (x_q, y_r) in the plane of the independent variables x and y , for each $q=1,2,\dots,m$ and $r=1,2,\dots,n$ (so that the points (x_q, y_r) lie at the $m \times n$ intersections of a rectangular mesh), E01DAF computes an interpolating bicubic spline, using a particular choice for

each of the spline's knot-set. This choice, the same as in E01BAF, has proved generally satisfactory in practice. If, instead, the user wishes to specify his own knots, a routine from Chapter E02, namely E02DAF, may be adapted (it is more cumbersome for the purpose, however, and much slower for larger problems). Using m and n in the above sense, the parameter M must be set to $m*n$, PX and PY must be set to $m+4$ and $n+4$ respectively and all elements of W should be set to unity. The recommended value for EPS is zero.

3.3.2. Arbitrary data

As remarked at the end of Section 2, special types of interpolating are required for this problem, which can often be difficult to solve satisfactorily. Two of the most successful are employed in E01SAF and E01SEF, the two routines which (with their respective evaluation routines E01SBF and E01SFF) are provided for the problem. Definitions can be found in the routine documents. Both interpolants have first derivative continuity and are 'local', in that their value at any point depends only on data in the immediate neighbourhood of the point. This latter feature is necessary for large sets of data to avoid prohibitive computing time.

The relative merits of the two methods vary with the data and it is not possible to predict which will be the better in any particular case.

E01BAF

E01BAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E01BAF determines a cubic spline interpolant to a given set of data.

2. Specification

```

SUBROUTINE E01BAF (M, X, Y, LAMDA, C, LCK, WRK, LWRK,
1                IFAIL)
  INTEGER          M, LCK, LWRK, IFAIL
  DOUBLE PRECISION X(M), Y(M), LAMDA(LCK), C(LCK), WRK(LWRK)

```

3. Description

This routine determines a cubic spline $s(x)$, defined in the range $x_1 \leq x \leq x_m$, which interpolates (passes exactly through) the set of data points (x_i, y_i) , for $i=1,2,\dots,m$, where $m \geq 4$ and $x_1 < x_2 < \dots < x_m$. end conditions are not imposed. The spline interpolant chosen has $m-4$ interior knots $(\lambda_5), (\lambda_6), \dots, (\lambda_{m-2})$, which are set to the values of x_3, x_4, \dots, x_{m-2} respectively. This spline is represented in its B-spline form (see Cox [1]):

$$s(x) = \sum_{i=1}^m c_i N_i(x),$$

where $N_i(x)$ denotes the normalised B-Spline of degree 3, defined upon the knots $(\lambda_i), (\lambda_{i+1}), \dots, (\lambda_{i+4})$, and c_i denotes its coefficient, whose value is to be determined by the routine.

The use of B-splines requires eight additional knots $(\lambda_1),$

1

(lambda)₂ , (lambda)₃ , (lambda)₄ , (lambda)_{m+1} , (lambda)_{m+2} ,
 (lambda)_{m+3} and (lambda)_{m+4} to be specified; the routine sets the
 first four of these to x_1 and the last four to x_m .

The algorithm for determining the coefficients is as described in [1] except that QR factorization is used instead of LU decomposition. The implementation of the algorithm involves setting up appropriate information for the related routine E02BAF followed by a call of that routine. (For further details of E02BAF, see the routine document.)

Values of the spline interpolant, or of its derivatives or definite integral, can subsequently be computed as detailed in Section 8.

- [2] Cox M G (1977) A Survey of Numerical Methods for Data and Function Approximation. The State of the Art in Numerical Analysis. (ed D A H Jacobs) Academic Press. 627--668.

5. Parameters

- 1: M -- INTEGER Input
 On entry: m, the number of data points. Constraint: M >= 4.
- 2: X(M) -- DOUBLE PRECISION array Input
 On entry: X(i) must be set to x_i , the ith data value of the independent variable x, for i=1,2,...,m. Constraint: X(i) < X(i+1), for i=1,2,...,M-1.
- 3: Y(M) -- DOUBLE PRECISION array Input
 On entry: Y(i) must be set to y_i , the ith data value of the dependent variable y, for i=1,2,...,m.
- 4: LAMDA(LCK) -- DOUBLE PRECISION array Output
 On exit: the value of (lambda)_i, the ith knot, for

- i
- $i=1,2,\dots,m+4.$
- 5: C(LCK) -- DOUBLE PRECISION array Output
 On exit: the coefficient c_i of the B-spline $N(x)$, for
 $i=1,2,\dots,m$. The remaining elements of the array are not
 used.
- 6: LCK -- INTEGER Input
 On entry:
 the dimension of the arrays LAMDA and C as declared in the
 (sub)program from which E01BAF is called.
 Constraint: LCK \geq M + 4.
- 7: WRK(LWRK) -- DOUBLE PRECISION array Workspace
- 8: LWRK -- INTEGER Input
 On entry:
 the dimension of the array WRK as declared in the
 (sub)program from which E01BAF is called.
 Constraint: LWRK \geq 6*M+16.
- 9: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not
 familiar with this parameter (described in the Essential
 Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see
 Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

On entry M < 4,

or LCK < M+4,

or LWRK < 6*M+16.

IFAIL= 2

The X-values fail to satisfy the condition

$X(1) < X(2) < X(3) < \dots < X(M).$

7. Accuracy

The rounding errors incurred are such that the computed spline is an exact interpolant for a slightly perturbed set of ordinates $y_i + (\delta y)_i$. The ratio of the root-mean-square value of the $(\delta y)_i$ to that of the y_i is no greater than a small multiple of the relative machine precision.

8. Further Comments

The time taken by the routine is approximately proportional to m .

All the x_i are used as knot positions except x_2 and x_{m-1} . This choice of knots (see Cox [2]) means that $s(x)$ is composed of $m-3$ cubic arcs as follows. If $m=4$, there is just a single arc space spanning the whole interval x_1 to x_4 . If $m \geq 5$, the first and last arcs span the intervals x_1 to x_4 and x_3 to x_m respectively. Additionally if $m \geq 6$, the i th arc, for $i=2,3,\dots,m-4$ spans the interval x_{i+1} to x_{i+2} .

After the call

```
CALL E01BAF (M, X, Y, LAMDA, C, LCK, WRK, LWRK, IFAIL)
```

the following operations may be carried out on the interpolant $s(x)$.

The value of $s(x)$ at $x = XVAL$ can be provided in the real variable $SVAL$ by the call

```
CALL E02BBF (M+4, LAMDA, C, XVAL, SVAL, IFAIL)
```

The values of $s(x)$ and its first three derivatives at $x = XVAL$ can be provided in the real array $SDIF$ of dimension 4, by the call

```
CALL E02BCF (M+4, LAMDA, C, XVAL, LEFT, SDIF, IFAIL)
```

Here $LEFT$ must specify whether the left- or right-hand value of

the third derivative is required (see E02BCF for details).

The value of the integral of $s(x)$ over the range x_1 to x_m can be provided in the real variable SINT by

```
CALL E02BDF (M+4, LAMDA, C, SINT, IFAIL)
```

9. Example

The example program sets up data from 7 values of the exponential function in the interval 0 to 1. E01BAF is then called to compute a spline interpolant to these data.

The spline is evaluated by E02BBF, at the data points and at points halfway between each adjacent pair of data points, and the spline values and the values of e^x are printed out.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E01 -- Interpolation

E01BEF

E01BEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E01BEF computes a monotonicity-preserving piecewise cubic Hermite interpolant to a set of data points.

2. Specification

```
SUBROUTINE E01BEF (N, X, F, D, IFAIL)
  INTEGER          N, IFAIL
  DOUBLE PRECISION X(N), F(N), D(N)
```

3. Description

This routine estimates first derivatives at the set of data points (x_r, f_r) , for $r=1,2,\dots,n$, which determine a piecewise cubic Hermite interpolant to the data, that preserves monotonicity over ranges where the data points are monotonic. If the data points are only piecewise monotonic, the interpolant will have an extremum at each point where monotonicity switches direction. The estimates of the derivatives are computed by a formula due to Brodlie, which is described in Fritsch and Butland [1], with suitable changes at the boundary points.

The routine is derived from routine PCHIM in Fritsch [2].

Values of the computed interpolant, and of its first derivative and definite integral, can subsequently be computed by calling E01BFF, E01BGF and E01BHF, as described in Section 8

4. References

- [1] Fritsch F N and Butland J (1984) A Method for Constructing Local Monotone Piecewise Cubic Interpolants. SIAM J. Sci. Statist. Comput. 5 300--304.
- [2] Fritsch F N (1982) PCHIP Final Specifications. Report UCID-30194. Lawrence Livermore National Laboratory.

5. Parameters

- 1: N -- INTEGER Input
On entry: n, the number of data points. Constraint: $N \geq 2$.
- 2: X(N) -- DOUBLE PRECISION array Input
On entry: $X(r)$ must be set to x_r , the rth value of the independent variable (abscissa), for $r=1,2,\dots,n$.
Constraint: $X(r) < X(r+1)$.
- 3: F(N) -- DOUBLE PRECISION array Input
On entry: $F(r)$ must be set to f_r , the rth value of the dependent variable (ordinate), for $r=1,2,\dots,n$.
- 4: D(N) -- DOUBLE PRECISION array Output
On exit: estimates of derivatives at the data points. D(r) contains the derivative at $X(r)$.

5: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry $N < 2$.

IFAIL= 2

The values of $X(r)$, for $r=1,2,\dots,N$, are not in strictly increasing order.

7. Accuracy

The computational errors in the array D should be negligible in most practical situations.

8. Further Comments

The time taken by the routine is approximately proportional to n .

The values of the computed interpolant at the points $PX(i)$, for $i=1,2,\dots,M$, may be obtained in the real array PF, of length at least M, by the call:

```
CALL E01BFF(N,X,F,D,M,PX,PF,IFAIL)
```

where N, X and F are the input parameters to E01BEF and D is the output parameter from E01BEF.

The values of the computed interpolant at the points $PX(i)$, for $i = 1,2,\dots,M$, together with its first derivatives, may be obtained in the real arrays PF and PD, both of length at least M, by the call:

```
CALL E01BGF(N,X,F,D,M,PX,PF,PD,IFAIL)
```

where N, X, F and D are as described above.

The value of the definite integral of the interpolant over the interval A to B can be obtained in the real variable PINT by the call:

```
CALL E01BHF(N,X,F,D,A,B,PINT,IFAIL)
```

where N, X, F and D are as described above.

9. Example

This example program reads in a set of data points, calls E01BEF to compute a piecewise monotonic interpolant, and then calls E01BFF to evaluate the interpolant at equally spaced points.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

```
%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%
```

E01 -- Interpolation

E01BFF

E01BFF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E01BFF evaluates a piecewise cubic Hermite interpolant at a set of points.

2. Specification

```
SUBROUTINE E01BFF (N, X, F, D, M, PX, PF, IFAIL)
  INTEGER          N, M, IFAIL
  DOUBLE PRECISION X(N), F(N), D(N), PX(M), PF(M)
```

3. Description

This routine evaluates a piecewise cubic Hermite interpolant, as

computed by E01BEF, at the points $PX(i)$, for $i=1,2,\dots,m$. If any point lies outside the interval from $X(1)$ to $X(N)$, a value is extrapolated from the nearest extreme cubic, and a warning is returned.

The routine is derived from routine PCHFE in Fritsch [1].

4. References

- [1] Fritsch F N (1982) PCHIP Final Specifications. Report UCID-30194. Lawrence Livermore National Laboratory.

5. Parameters

- | | |
|---|--------------|
| 1: N -- INTEGER | Input |
| 2: X(N) -- DOUBLE PRECISION array | Input |
| 3: F(N) -- DOUBLE PRECISION array | Input |
| 4: D(N) -- DOUBLE PRECISION array | Input |
| On entry: N, X, F and D must be unchanged from the previous call of E01BEF. | |
| 5: M -- INTEGER | Input |
| On entry: m, the number of points at which the interpolant is to be evaluated. Constraint: $M \geq 1$. | |
| 6: PX(M) -- DOUBLE PRECISION array | Input |
| On entry: the m values of x at which the interpolant is to be evaluated. | |
| 7: PF(M) -- DOUBLE PRECISION array | Output |
| On exit: PF(i) contains the value of the interpolant evaluated at the point $PX(i)$, for $i=1,2,\dots,m$. | |
| 8: IFAIL -- INTEGER | Input/Output |
| On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0. | |
| On exit: IFAIL = 0 unless the routine detects an error (see Section 6). | |

6. Error Indicators and Warnings

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

```
IFAIL= 2
      The values of X(r), for r = 1,2,...,N, are not in strictly
      increasing order.
```

IFAIL= 4

At least one of the points PX(i), for $i = 1, 2, \dots, M$, lies outside the interval $[X(1), X(N)]$, and extrapolation was performed at all such points. Values computed at such points may be very unreliable.

The computational errors in the array PF should be negligible in most practical situations.

The time taken by the routine is approximately proportional to the number of evaluation points, m . The evaluation will be most efficient if the elements of PX are in non-decreasing order (or, more generally, if they are grouped in increasing order of the intervals $[X(r-1), X(r)]$). A single call of `E01BFF` with $m > 1$ is more efficient than several calls with $m = 1$.

This example program reads in values of N, X, F and D, and then calls E01BFF to evaluate the interpolant at equally spaced points.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E01 -- Interpolation E01BGF
 E01BGF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E01BGF evaluates a piecewise cubic Hermite interpolant and its first derivative at a set of points.

2. Specification

```
SUBROUTINE E01BGF (N, X, F, D, M, PX, PF, PD, IFAIL)
  INTEGER          N, M, IFAIL
  DOUBLE PRECISION X(N), F(N), D(N), PX(M), PF(M), PD(M)
```

3. Description

This routine evaluates a piecewise cubic Hermite interpolant, as computed by E01BEF, at the points $PX(i)$, for $i=1,2,\dots,m$. The first derivatives at the points are also computed. If any point lies outside the interval from $X(1)$ to $X(N)$, values of the interpolant and its derivative are extrapolated from the nearest extreme cubic, and a warning is returned.

If values of the interpolant only, and not of its derivative, are required, E01BFF should be used.

The routine is derived from routine PCHFD in Fritsch [1].

4. References

- [1] Fritsch F N (1982) PCHIP Final Specifications. Report UCID-30194. Lawrence Livermore National Laboratory.

5. Parameters

1: N -- INTEGER	Input
2: X(N) -- DOUBLE PRECISION array	Input
3: F(N) -- DOUBLE PRECISION array	Input

- 4: D(N) -- DOUBLE PRECISION array Input
 On entry: N, X, F and D must be unchanged from the previous call of E01BEF.
- 5: M -- INTEGER Input
 On entry: m, the number of points at which the interpolant is to be evaluated. Constraint: $M \geq 1$.
- 6: PX(M) -- DOUBLE PRECISION array Input
 On entry: the m values of x at which the interpolant is to be evaluated.
- 7: PF(M) -- DOUBLE PRECISION array Output
 On exit: PF(i) contains the value of the interpolant evaluated at the point PX(i), for $i=1,2,\dots,m$.
- 8: PD(M) -- DOUBLE PRECISION array Output
 On exit: PD(i) contains the first derivative of the interpolant evaluated at the point PX(i), for $i=1,2,\dots,m$.
- 9: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry $N < 2$.

IFAIL= 2

The values of X(r), for $r = 1,2,\dots,N$, are not in strictly increasing order.

IFAIL= 3

On entry $M < 1$.

IFAIL= 4

At least one of the points $PX(i)$, for $i = 1, 2, \dots, M$, lies outside the interval $[X(1), X(N)]$, and extrapolation was performed at all such points. Values computed at these points may be very unreliable.

7. Accuracy

The computational errors in the arrays PF and PD should be negligible in most practical situations.

8. Further Comments

The time taken by the routine is approximately proportional to the number of evaluation points, m . The evaluation will be most efficient if the elements of PX are in non-decreasing order (or, more generally, if they are grouped in increasing order of the intervals $[X(r-1), X(r)]$). A single call of E01BGF with $m > 1$ is more efficient than several calls with $m = 1$.

9. Example

This example program reads in values of N , X , F and D , and calls E01BGF to compute the values of the interpolant and its derivative at equally spaced points.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E01 -- Interpolation

E01BHF

E01BHF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E01BHF evaluates the definite integral of a piecewise cubic Hermite interpolant over the interval $[a, b]$.

2. Specification

```

SUBROUTINE E01BHF (N, X, F, D, A, B, PINT, IFAIL)
  INTEGER          N, IFAIL
  DOUBLE PRECISION X(N), F(N), D(N), A, B, PINT

```

3. Description

This routine evaluates the definite integral of a piecewise cubic Hermite interpolant, as computed by E01BEF, over the interval $[a,b]$.

If either a or b lies outside the interval from $X(1)$ to $X(N)$ computation of the integral involves extrapolation and a warning is returned.

The routine is derived from routine PCHIA in Fritsch [1].

4. References

- [1] Fritsch F N (1982) PCHIP Final Specifications. Report UCID-30194. Lawrence Livermore National Laboratory .

5. Parameters

- | | |
|--|--------------|
| 1: N -- INTEGER | Input |
| 2: X(N) -- DOUBLE PRECISION array | Input |
| 3: F(N) -- DOUBLE PRECISION array | Input |
| 4: D(N) -- DOUBLE PRECISION array | Input |
| On entry: N, X, F and D must be unchanged from the previous call of E01BEF. | |
| 5: A -- DOUBLE PRECISION | Input |
| 6: B -- DOUBLE PRECISION | Input |
| On entry: the interval $[a,b]$ over which integration is to be performed. | |
| 7: PINT -- DOUBLE PRECISION | Output |
| On exit: the value of the definite integral of the interpolant over the interval $[a,b]$. | |
| 8: IFAIL -- INTEGER | Input/Output |
| On entry: IFAIL must be set to 0, -1 or 1. For users not | |

familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry $N < 2$.

IFAIL= 2

The values of $X(r)$, for $r = 1, 2, \dots, N$, are not in strictly increasing order.

IFAIL= 3

On entry at least one of A or B lies outside the interval $[X(1), X(N)]$, and extrapolation was performed to compute the integral. The value returned is therefore unreliable.

7. Accuracy

The computational error in the value returned for PINT should be negligible in most practical situations.

8. Further Comments

The time taken by the routine is approximately proportional to the number of data points included within the interval $[a, b]$.

9. Example

This example program reads in values of N, X, F and D. It then reads in pairs of values for A and B, and evaluates the definite integral of the interpolant over the interval $[A, B]$ until end-of-file is reached.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%

E01 -- Interpolation

E01DAF

E01DAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E01DAF computes a bicubic spline interpolating surface through a set of data values, given on a rectangular grid in the x-y plane.

2. Specification

```

      SUBROUTINE E01DAF (MX, MY, X, Y, F, PX, PY, LAMDA, MU, C,
1      WRK, IFAIL)
      INTEGER          MX, MY, PX, PY, IFAIL
      DOUBLE PRECISION X(MX), Y(MY), F(MX*MY), LAMDA(MX+4), MU(MX
1      +4), C(MX*MY), WRK((MX+6)*(MY+6))

```

3. Description

This routine determines a bicubic spline interpolant to the set of data points (x_{qr}, y_{qr}, f_{qr}) , for $q=1,2,\dots,m$; $r=1,2,\dots,m$. The spline is given in the B-spline representation

$$s(x,y) = \sum_{i=1}^m \sum_{j=1}^m c_{ij} M_i(x) N_j(y),$$

such that

$$s(x_{qr}, y_{qr}) = f_{qr},$$

where $M_i(x)$ and $N_j(y)$ denote normalised cubic B-splines, the former defined on the knots (λ_i) to (λ_{i+4}) and the

latter on the knots $(\mu)_j$ to $(\mu)_{j+4}$, and the c_{ij} are the spline coefficients. These knots, as well as the coefficients, are determined by the routine, which is derived from the routine B2IRE in Anthony et al[1]. The method used is described in Section 8.2.

For further information on splines, see Hayes and Halliday [4] for bicubic splines and de Boor [3] for normalised B-splines.

Values of the computed spline can subsequently be obtained by calling E02DEF or E02DFF as described in Section 8.3.

5. Parameters

- 1: MX -- INTEGER Input
- 2: MY -- INTEGER Input
 On entry: MX and MY must specify m_x and m_y respectively,
 the number of points along the x and y axis that define the
 rectangular grid. Constraint: $MX \geq 4$ and $MY \geq 4$.
- 3: X(MX) -- DOUBLE PRECISION array Input
- 4: Y(MY) -- DOUBLE PRECISION array Input
 On entry: X(q) and Y(r) must contain x_q , for $q=1,2,\dots,m_x$,
 and y_r , for $r=1,2,\dots,m_y$, respectively. Constraints:

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry $MX < 4$,

or $MY < 4$.

IFAIL= 2

On entry either the values in the X array or the values in the Y array are not in increasing order.

IFAIL= 3

A system of linear equations defining the B-spline coefficients was singular; the problem is too ill-conditioned to permit solution.

7. Accuracy

The main sources of rounding errors are in steps (2), (3), (6) and (7) of the algorithm described in Section 8.2. It can be shown (Cox [2]) that the matrix A formed in step (2) has

x
elements differing relatively from their true values by at most a small multiple of $3(\epsilon)$, where (ϵ) is the machine precision. A is 'totally positive', and a linear system with

x
such a coefficient matrix can be solved quite safely by elimination without pivoting. Similar comments apply to steps (6) and (7). Thus the complete process is numerically stable.

8. Further Comments

8.1. Timing

The time taken by this routine is approximately proportional to $m \cdot m$.

$x \cdot y$

8.2. Outline of method used

The process of computing the spline consists of the following steps:

- (1) choice of the interior x-knots $(\lambda_5), (\lambda_6), \dots, (\lambda_m)$ as $(\lambda_i) = x_{i-2}$, for $i=5, 6, \dots, m$,
 x
- (2) formation of the system $A_x E = F_x$,
 where A_x is a band matrix of order m and bandwidth 4, containing in its q th row the values at x_q of the B-splines in x , F is the m by m rectangular matrix of values $f_{q,r}$,
 x y and E denotes an m by m rectangular matrix of intermediate coefficients,
 x y
- (3) use of Gaussian elimination to reduce this system to band triangular form,
- (4) solution of this triangular system for E ,
- (5) choice of the interior y knots $(\mu_5), (\mu_6), \dots, (\mu_m)$ as
 $(\mu_i) = y_{i-2}$, for $i=5, 6, \dots, m$,
 y
- (6) formation of the system $A_y^T C_y^T = E_y$,
 where A_y is the counterpart of A_x for the y variable, and C_y denotes the m by m rectangular matrix of values of c_{ij} ,
 x y
- (7) use of Gaussian elimination to reduce this system to band

triangular form,

- (8) solution of this triangular system for C^T and hence C .

For computational convenience, steps (2) and (3), and likewise steps (6) and (7), are combined so that the formation of A and x and the reductions to triangular form are carried out one row y at a time.

8.3. Evaluation of Computed Spline

The values of the computed spline at the points $(TX(r), TY(r))$, for $r = 1, 2, \dots, N$, may be obtained in the double precision array FF , of length at least N , by the following call:

```
IFAIL = 0
CALL E02DEF(N,PX,PY,TX,TY,LAMDA,MU,C,FF,WRK,IWRK,IFAIL)
```

where PX , PY , $LAMDA$, MU and C are the output parameters of $E01DAF$, WRK is a double precision workspace array of length at least $PY-4$, and $IWRK$ is an integer workspace array of length at least $PY-4$.

To evaluate the computed spline on an NX by NY rectangular grid of points in the x - y plane, which is defined by the x coordinates stored in $TX(q)$, for $q = 1, 2, \dots, NX$, and the y coordinates stored in $TY(r)$, for $r = 1, 2, \dots, NY$, returning the results in the double precision array FG which is of length at least $NX*NY$, the following call may be used:

```
IFAIL = 0
CALL E02DFF(NX,NY,PX,PY,TX,TY,LAMDA,MU,C,FG,WRK,LWRK,
*          IWRK,LIWRK,IFAIL)
```

where PX , PY , $LAMDA$, MU and C are the output parameters of $E01DAF$, WRK is a double precision workspace array of length at least $LWRK = \min(NWRK1, NWRK2)$, $NWRK1 = NX*4+PX$, $NWRK2 = NY*4+PY$, and $IWRK$ is an integer workspace array of length at least $LIWRK = NY + PY - 4$ if $NWRK1 > NWRK2$, or $NX + PX - 4$ otherwise. The result of the spline evaluated at grid point (q,r) is returned in element $(NY*(q-1)+r)$ of the array FG .

9. Example

This program reads in values of m , x_q for $q=1,2,\dots,m$, m and y_r for $r=1,2,\dots,m$, followed by values of the ordinates $f_{q,r}$ defined at the grid points (x_q, y_r) . It then calls E01DAF to compute a bicubic spline interpolant of the data values, and prints the values of the knots and B-spline coefficients. Finally it evaluates the spline at a small sample of points on a rectangular grid.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E01 -- Interpolation E01SAF
 E01SAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E01SAF generates a two-dimensional surface interpolating a set of scattered data points, using the method of Renka and Cline.

2. Specification

```
SUBROUTINE E01SAF (M, X, Y, F, TRIANG, GRADS, IFAIL)
  INTEGER          M, TRIANG(7*M), IFAIL
  DOUBLE PRECISION X(M), Y(M), F(M), GRADS(2,M)
```

3. Description

This routine constructs an interpolating surface $F(x,y)$ through a set of m scattered data points (x_r, y_r, f_r) , for $r=1,2,\dots,m$, using a method due to Renka and Cline. In the (x,y) plane, the data points must be distinct. The constructed surface is continuous

and has continuous first derivatives.

The method involves firstly creating a triangulation with all the (x,y) data points as nodes, the triangulation being as nearly equiangular as possible (see Cline and Renka [1]). Then gradients in the x - and y -directions are estimated at node r , for $r=1,2,\dots,m$, as the partial derivatives of a quadratic function of x and y which interpolates the data value f_r , and which fits

the data values at nearby nodes (those within a certain distance chosen by the algorithm) in a weighted least-squares sense. The weights are chosen such that closer nodes have more influence than more distant nodes on derivative estimates at node r . The computed partial derivatives, with the f_r values, at the three

nodes of each triangle define a piecewise polynomial surface of a certain form which is the interpolant on that triangle. See Renka and Cline [4] for more detailed information on the algorithm, a development of that by Lawson [2]. The code is derived from Renka [3].

The interpolant $F(x,y)$ can subsequently be evaluated at any point (x,y) inside or outside the domain of the data by a call to E01SBF. Points outside the domain are evaluated by extrapolation.

5. Parameters

- 1: M -- INTEGER Input
On entry: m, the number of data points. Constraint: $M \geq 3$.
- 2: X(M) -- DOUBLE PRECISION array Input
- 3: Y(M) -- DOUBLE PRECISION array Input
- 4: F(M) -- DOUBLE PRECISION array Input
On entry: the co-ordinates of the rth data point, for $r=1,2,\dots,m$. The data points are accepted in any order, but see Section 8. Constraint: The (x,y) nodes must not all be collinear, and each node must be unique.
- 5: TRIANG(7*M) -- INTEGER array Output
On exit: a data structure defining the computed triangulation, in a form suitable for passing to E01SBF.
- 6: GRADS(2,M) -- DOUBLE PRECISION array Output
On exit: the estimated partial derivatives at the nodes, in a form suitable for passing to E01SBF. The derivatives at node r with respect to x and y are contained in GRADS(1,r) and GRADS(2,r) respectively, for $r=1,2,\dots,m$.
- 7: IFAIL -- INTEGER Input/Output
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry $M < 3$.

IFAIL= 2

On entry all the (X,Y) pairs are collinear.

IFAIL= 3

On entry $(X(i),Y(i)) = (X(j),Y(j))$ for some $i \neq j$.

7. Accuracy

On successful exit, the computational errors should be negligible in most situations but the user should always check the computed surface for acceptability, by drawing contours for instance. The surface always interpolates the input data exactly.

8. Further Comments

The time taken for a call of E01SAF is approximately proportional to the number of data points, m . The routine is more efficient if, before entry, the values in X , Y , F are arranged so that the X array is in ascending order.

9. Example

This program reads in a set of 30 data points and calls E01SAF to construct an interpolating surface. It then calls E01SBF to evaluate the interpolant at a sample of points on a rectangular grid.

Note that this example is not typical of a realistic problem: the number of data points would normally be larger, and the interpolant would need to be evaluated on a finer grid to obtain an accurate plot, say.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E01 -- Interpolation

E01SBF

E01SBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E01SBF evaluates at a given point the two-dimensional interpolant function computed by E01SAF.

2. Specification

```

SUBROUTINE E01SBF (M, X, Y, F, TRIANG, GRADS, PX, PY, PF,
1                IFAIL)
  INTEGER          M, TRIANG(7*M), IFAIL
  DOUBLE PRECISION X(M), Y(M), F(M), GRADS(2,M), PX, PY, PF

```

3. Description

This routine takes as input the parameters defining the interpolant $F(x,y)$ of a set of scattered data points (x_r, y_r, f_r) , for $r=1,2,\dots,m$, as computed by E01SAF, and evaluates the interpolant at the point (px,py) .

If (px,py) is equal to (x_r, y_r) for some value of r , the returned value will be equal to f_r .

If (px,py) is not equal to (x_r, y_r) for any r , the derivatives in GRADS will be used to compute the interpolant. A triangle is sought which contains the point (px,py) , and the vertices of the triangle along with the partial derivatives and f_r values at the vertices are used to compute the value $F(px,py)$. If the point (px,py) lies outside the triangulation defined by the input parameters, the returned value is obtained by extrapolation. In this case, the interpolating function F is extended linearly beyond the triangulation boundary. The method is described in more detail in Renka and Cline [2] and the code is derived from Renka [1].

E01SBF must only be called after a call to E01SAF.

4. References

5. Parameters

- | | |
|---|--------------|
| 1: M -- INTEGER | Input |
| 2: X(M) -- DOUBLE PRECISION array | Input |
| 3: Y(M) -- DOUBLE PRECISION array | Input |
| 4: F(M) -- DOUBLE PRECISION array | Input |
| 5: TRIANG(7*M) -- INTEGER array | Input |
| 6: GRADS(2,M) -- DOUBLE PRECISION array | Input |
| On entry: M, X, Y, F, TRIANG and GRADS must be unchanged from the previous call of E01SAF. | |
| 7: PX -- DOUBLE PRECISION | Input |
| 8: PY -- DOUBLE PRECISION | Input |
| On entry: the point (px,py) at which the interpolant is to be evaluated. | |
| 9: PF -- DOUBLE PRECISION | Output |
| On exit: the value of the interpolant evaluated at the point (px,py). | |
| 10: IFAIL -- INTEGER | Input/Output |
| On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0. | |
| On exit: IFAIL = 0 unless the routine detects an error (see Section 6). | |

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry M < 3.

IFAIL= 2

On entry the triangulation information held in the array

TRIANG does not specify a valid triangulation of the data points. TRIANG may have been corrupted since the call to E01SAF.

IFAIL= 3

The evaluation point (PX,PY) lies outside the nodal triangulation, and the value returned in PF is computed by extrapolation.

7. Accuracy

Computational errors should be negligible in most practical situations.

8. Further Comments

The time taken for a call of E01SBF is approximately proportional to the number of data points, m .

The results returned by this routine are particularly suitable for applications such as graph plotting, producing a smooth surface from a number of scattered points.

9. Example

See the example for E01SAF.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E01 -- Interpolation

E01SEF

E01SEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E01SEF generates a two-dimensional surface interpolating a set of scattered data points, using a modified Shepard method.

2. Specification

```

SUBROUTINE E01SEF (M, X, Y, F, RNW, RNQ, NW, NQ, FNODES,
1                MINNQ, WRK, IFAIL)
  INTEGER          M, NW, NQ, MINNQ, IFAIL
  DOUBLE PRECISION X(M), Y(M), F(M), RNW, RNQ, FNODES(5*M),
1                WRK(6*M)

```

3. Description

This routine constructs an interpolating surface $F(x,y)$ through a set of m scattered data points (x_r, y_r, f_r) , for $r=1,2,\dots,m$, using a modification of Shepard's method. The surface is continuous and has continuous first derivatives.

The basic Shepard method, described in [2], interpolates the input data with the weighted mean

$$F(x,y) = \frac{\sum_{r=1}^m w_r(x,y) f_r}{\sum_{r=1}^m w_r(x,y)},$$

$$\text{where } w_r(x,y) = \frac{1}{d_r^2} \text{ and } d_r^2 = (x - x_r)^2 + (y - y_r)^2.$$

The basic method is global in that the interpolated value at any point depends on all the data, but this routine uses a modification due to Franke and Nielson described in [1], whereby the method becomes local by adjusting each $w_r(x,y)$ to be zero

outside a circle with centre (x_r, y_r) and some radius R . Also, to improve the performance of the basic method, each f_r above is

replaced by a function $f(x,y)$, which is a quadratic fitted by weighted least-squares to data local to (x_r, y_r) and forced to interpolate (x_r, y_r, f_r) . In this context, a point (x,y) is defined to be local to another point if it lies within some distance R_q of it. Computation of these quadratics constitutes the main work done by this routine. If there are less than 5 other points within distance R_q from (x_r, y_r) , the quadratic is replaced by a linear function. In cases of rank-deficiency, the minimum norm solution is computed.

The user may specify values for R_w and R_q , but it is usually easier to choose instead two integers N_w and N_q , from which the routine will compute R_w and R_q . These integers can be thought of as the average numbers of data points lying within distances R_w and R_q respectively from each node. Default values are provided, and advice on alternatives is given in Section 8.2.

The interpolant $F(x,y)$ generated by this routine can subsequently be evaluated for any point (x,y) in the domain of the data by a call to E01SFF.

4. References

- [1] Franke R and Nielson G (1980) Smooth Interpolation of Large Sets of Scattered Data. Internat. J. Num. Methods Engrg. 15 1691--1704.
- [2] Shepard D (1968) A Two-dimensional Interpolation Function for Irregularly Spaced Data. Proc. 23rd Nat. Conf. ACM. Brandon/Systems Press Inc., Princeton. 517--523.

5. Parameters

1: M -- INTEGER Input
 On entry: m, the number of data points. Constraint: M >= 3.

- 2: X(M) -- DOUBLE PRECISION array Input
- 3: Y(M) -- DOUBLE PRECISION array Input
- 4: F(M) -- DOUBLE PRECISION array Input
 On entry: the co-ordinates of the rth data point, for
 $r=1,2,\dots,m$. The order of the data points is immaterial.
 Constraint: each of the $(X(r),Y(r))$ pairs must be unique.
- 5: RNW -- DOUBLE PRECISION Input/Output
- 6: RNQ -- DOUBLE PRECISION Input/Output
 On entry: suitable values for the radii R_w and R_q ,
 described in Section 3. Constraint: $RNQ \leq 0$ or $0 < RNW \leq$
 RNQ . On exit: if RNQ is set less than or equal to zero on
 entry, then default values for both of them will be computed
 from the parameters NW and NQ, and RNW and RNQ will contain
 these values on exit.
- 7: NW -- INTEGER Input
- 8: NQ -- INTEGER Input
 On entry: if $RNQ > 0.0$ and $RNW > 0.0$ then NW and NQ are not
 referenced by the routine. Otherwise, NW and NQ must specify
 suitable values for the integers N_w and N_q described in
 Section 3.
- If NQ is less than or equal to zero on entry, then default
 values for both of them, namely $NW = 9$ and $NQ = 18$, will be
 used. Constraint: $NQ \leq 0$ or $0 < NW \leq NQ$.
- 9: FNODES(5*M) -- DOUBLE PRECISION array Output
 On exit: the coefficients of the constructed quadratic
 nodal functions. These are in a form suitable for passing to
 EO1SFF.
- 10: MINNQ -- INTEGER Output
 On exit: the minimum number of data points that lie within
 radius RNQ of any node, and thus define a nodal function. If
 MINNQ is very small (say, less than 5), then the interpolant
 may be unsatisfactory in regions where the data points are
 sparse.
- 11: WRK(6*M) -- DOUBLE PRECISION array Workspace

12: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1
 On entry $M < 3$.

IFAIL= 2
 On entry $RNQ > 0$ and either $RNW > RNQ$ or $RNW \leq 0$.

IFAIL= 3
 On entry $NQ > 0$ and either $NW > NQ$ or $NW \leq 0$.

IFAIL= 4
 On entry $(X(i), Y(i))$ is equal to $(X(j), Y(j))$ for some $i \neq j$.

7. Accuracy

On successful exit, the computational errors should be negligible in most situations but the user should always check the computed surface for acceptability, by drawing contours for instance. The surface always interpolates the input data exactly.

8. Further Comments

8.1. Timing

The time taken for a call of E01SEF is approximately proportional to the number of data points, m , provided that N is of the same order as its default value (18). However if N is increased so that the method becomes more global, the time taken becomes

approximately proportional to m .

$$m N_w \text{ and } m N_q$$

8.2. Choice of N

Note first that the radii R_w and R_q , described in Section 3, are

computed as $\frac{D}{2\sqrt{m}} \sqrt{\frac{N_w}{N}}$ and $\frac{D}{2\sqrt{m}} \sqrt{\frac{N_q}{N}}$ respectively, where D is

the maximum distance between any pair of data points.

Default values $N_w = 9$ and $N_q = 18$ work quite well when the data

points are fairly uniformly distributed. However, for data having some regions with relatively few points or for small data sets ($m < 25$), a larger value of N may be needed. This is to ensure a

reasonable number of data points within a distance R_w of each

node, and to avoid some regions in the data area being left outside all the discs of radius R_q on which the weights $w(x, y)$

are non-zero. Maintaining N_w approximately equal to $2N_q$ is usually an advantage.

Note however that increasing N_w and N_q does not improve the

quality of the interpolant in all cases. It does increase the computational cost and makes the method less local.

9. Example

This program reads in a set of 30 data points and calls E01SEF to construct an interpolating surface. It then calls E01SFF to evaluate the interpolant at a sample of points on a rectangular grid.

Note that this example is not typical of a realistic problem: the number of data points would normally be larger, and the interpolant would need to be evaluated on a finer grid to obtain an accurate plot, say.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation

Library software and should be available on-line.

E01 -- Interpolation E01SFF
 E01SFF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E01SFF evaluates at a given point the two-dimensional interpolating function computed by E01SEF.

2. Specification

```

      SUBROUTINE E01SFF (M, X, Y, F, RNW, FNODES, PX, PY, PF,
1      IFAIL)
      INTEGER          M, IFAIL
      DOUBLE PRECISION X(M), Y(M), F(M), RNW, FNODES(5*M), PX,
1      PY, PF

```

3. Description

This routine takes as input the interpolant $F(x,y)$ of a set of scattered data points (x_r, y_r, f_r) , for $r=1,2,\dots,m$, as computed by E01SEF, and evaluates the interpolant at the point (px,py) .

If (px,py) is equal to (x_r, y_r) for some value of r , the returned value will be equal to f_r .

If (px,py) is not equal to (x_r, y_r) for any r , all points that are within distance RNW of (px,py) , along with the corresponding nodal functions given by $FNODES$, will be used to compute a value of the interpolant.

E01SFF must only be called after a call to E01SEF.

4. References

- [1] Franke R and Nielson G (1980) Smooth Interpolation of Large Sets of Scattered Data. *Internat. J. Num. Methods Engrg.* 15 1691--1704.
- [2] Shepard D (1968) A Two-dimensional Interpolation Function for Irregularly Spaced Data. *Proc. 23rd Nat. Conf. ACM.* Brandon/Systems Press Inc., Princeton. 517--523.

5. Parameters

- | | | |
|-----|--|--------------|
| 1: | M -- INTEGER | Input |
| 2: | X(M) -- DOUBLE PRECISION array | Input |
| 3: | Y(M) -- DOUBLE PRECISION array | Input |
| 4: | F(M) -- DOUBLE PRECISION array | Input |
| 5: | RNW -- DOUBLE PRECISION | Input |
| 6: | FNODES(5*M) -- DOUBLE PRECISION array
On entry: M, X, Y, F, RNW and FNODES must be unchanged from the previous call of E01SEF. | Input |
| 7: | PX -- DOUBLE PRECISION | Input |
| 8: | PY -- DOUBLE PRECISION
On entry: the point (px,py) at which the interpolant is to be evaluated. | Input |
| 9: | PF -- DOUBLE PRECISION
On exit: the value of the interpolant evaluated at the point (px,py). | Output |
| 10: | IFAIL -- INTEGER
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6). | Input/Output |

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry $M < 3$.

IFAIL= 2

The interpolant cannot be evaluated because the evaluation point (PX,PY) lies outside the support region of the data supplied in X, Y and F. This error exit will occur if (PX,PY) lies at a distance greater than or equal to RNW from every point given by arrays X and Y.

The value 0.0 is returned in PF. This value will not provide continuity with values obtained at other points (PX,PY), i.e., values obtained when IFAIL = 0 on exit.

7. Accuracy

Computational errors should be negligible in most practical situations.

8. Further Comments

The time taken for a call of E01SFF is approximately proportional to the number of data points, m .

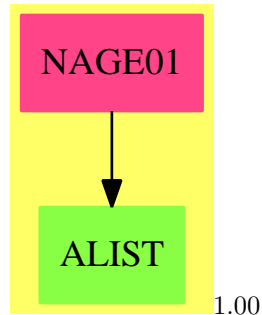

The results returned by this routine are particularly suitable for applications such as graph plotting, producing a smooth surface from a number of scattered points.

9. Example

See the example for E01SEF.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

<package NAGE01 NagInterpolationPackage>≡
)abbrev package NAGE01 NagInterpolationPackage
++ Author: Godfrey Nolan and Mike Dewar
++ Date Created: Jan 1994
++ Date Last Updated: Thu May 12 17:44:53 1994
++ Description:
++ This package uses the NAG Library to calculate the interpolation of a
++ function of one or two variables. When provided with the value of the
++ function (and possibly one or more of its lowest-order
++ derivatives) at each of a number of values of the variable(s),
++ the routines provide either an interpolating function or an
++ interpolated value. For some of the interpolating functions,
++ there are supporting routines to evaluate, differentiate or
++ integrate them.
++ See \downlink{Manual Page}{manpageXXe01}.
```

e01baf : (Integer,Matrix DoubleFloat,Matrix DoubleFloat,Integer,
Integer,Integer) -> Result
++ e01baf(m,x,y,lck,lwrk,ifail)
++ determines a cubic spline to a given set of
++ data.
++ See \downlink{Manual Page}{manpageXXe01baf}.
e01bef : (Integer,Matrix DoubleFloat,Matrix DoubleFloat,Integer) -> Result
++ e01bef(n,x,f,ifail)
```

```

++ computes a monotonicity-preserving piecewise cubic Hermite
++ interpolant to a set of data points.
++ See \downlink{Manual Page}{manpageXXe01bef}.
e01bff : (Integer,Matrix DoubleFloat,Matrix DoubleFloat,Matrix DoubleFloat,_,
Integer,Matrix DoubleFloat,Integer) -> Result
++ e01bff(n,x,f,d,m,px,ifail)
++ evaluates a piecewise cubic Hermite interpolant at a set
++ of points.
++ See \downlink{Manual Page}{manpageXXe01bff}.
e01bgf : (Integer,Matrix DoubleFloat,Matrix DoubleFloat,Matrix DoubleFloat,_,
Integer,Matrix DoubleFloat,Integer) -> Result
++ e01bgf(n,x,f,d,m,px,ifail)
++ evaluates a piecewise cubic Hermite interpolant and its
++ first derivative at a set of points.
++ See \downlink{Manual Page}{manpageXXe01bgf}.
e01bhf : (Integer,Matrix DoubleFloat,Matrix DoubleFloat,Matrix DoubleFloat,_,
DoubleFloat,DoubleFloat,Integer) -> Result
++ e01bhf(n,x,f,d,a,b,ifail)
++ evaluates the definite integral of a piecewise cubic
++ Hermite interpolant over the interval [a,b].
++ See \downlink{Manual Page}{manpageXXe01bhf}.
e01daf : (Integer,Integer,Matrix DoubleFloat,Matrix DoubleFloat,_,
Matrix DoubleFloat,Integer) -> Result
++ e01daf(mx,my,x,y,f,ifail)
++ computes a bicubic spline interpolating surface through a
++ set of data values, given on a rectangular grid in the x-y plane.
++ See \downlink{Manual Page}{manpageXXe01daf}.
e01saf : (Integer,Matrix DoubleFloat,Matrix DoubleFloat,Matrix DoubleFloat,_,
Integer) -> Result
++ e01saf(m,x,y,f,ifail)
++ generates a two-dimensional surface interpolating a set of
++ scattered data points, using the method of Renka and Cline.
++ See \downlink{Manual Page}{manpageXXe01saf}.
e01sbf : (Integer,Matrix DoubleFloat,Matrix DoubleFloat,Matrix DoubleFloat,_,
Matrix Integer,Matrix DoubleFloat,DoubleFloat,DoubleFloat,Integer) -> Result
++ e01sbf(m,x,y,f,triang,grads,px,py,ifail)
++ evaluates at a given point the two-dimensional interpolant
++ function computed by E01SAF.
++ See \downlink{Manual Page}{manpageXXe01sbf}.
e01sef : (Integer,Matrix DoubleFloat,Matrix DoubleFloat,Matrix DoubleFloat,_,
Integer,Integer,DoubleFloat,DoubleFloat,Integer) -> Result
++ e01sef(m,x,y,f,nw,nq,rnw,rnq,ifail)
++ generates a two-dimensional surface interpolating a set of
++ scattered data points, using a modified Shepard method.
++ See \downlink{Manual Page}{manpageXXe01sef}.
e01sff : (Integer,Matrix DoubleFloat,Matrix DoubleFloat,Matrix DoubleFloat,_,

1. Scope of the Chapter

2. Background to the Problems

3. Recommendations on Choice and Use of Routines

Routine F07ADF (DGETRF) performs an LU factorization of a real m by n matrix A. Following the use of this routine, F07AEF (DGETRS) may be used to solve a system of n non-singular linear equations, with one or more right-hand sides.

Routine F07FDF (DPOTRF) performs the Cholesky factorization of a real symmetric positive-definite matrix A. Following the use of this routine, F07FEF (DPOTRS) may be used to solve a system of symmetric positive-definite linear equations, with one or more right-hand sides.

F07 -- Linear Equations (LAPACK)

F07ADF

F07ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is
not included in the Foundation Library.

1. Purpose

F07ADF (DGETRF) computes the LU factorization of a real m by n
matrix.

2. Specification

```
SUBROUTINE F07ADF (M, N, A, LDA, IPIV, INFO)
  ENTRY           M, N, A, LDA, IPIV, INFO
  INTEGER         M, N, LDA, IPIV(*), INFO
  DOUBLE PRECISION A(LDA,*)
```

The ENTRY statement enables the routine to be called by its
LAPACK name.

3. Description

This routine forms the LU factorization of a real m by n matrix A
as $A=PLU$, where P is a permutation matrix, L is lower triangular
with unit diagonal elements (lower trapezoidal if $m>n$) and U is
upper triangular (upper trapezoidal if $m<n$). Usually A is square
($m=n$), and both L and U are triangular. The routine uses partial
pivoting, with row interchanges.

4. References

- [1] Golub G H and Van Loan C F (1989) Matrix Computations (2nd Edition). Johns Hopkins University Press, Baltimore, Maryland.

5. Parameters

- 1: M -- INTEGER Input
On entry: m, the number of rows of the matrix A.
Constraint: M \geq 0.
- 2: N -- INTEGER Input
On entry: n, the number of columns of the matrix A.
Constraint: N \geq 0.
- 3: A(LDA,*) -- DOUBLE PRECISION array Input/Output
Note: the second dimension of the array A must be at least max(1,N).
On entry: the m by n matrix A. On exit: A is overwritten by the factors L and U; the unit diagonal elements of L are not stored.
- 4: LDA -- INTEGER Input
On entry:
the first dimension of the array A as declared in the (sub)program from which F07ADF is called.
Constraint: LDA \geq max(1,M).
- 5: IPIV(*) -- INTEGER array Output
Note: the dimension of the array IPIV must be at least max(1,min(M,N)).
On exit: the pivot indices. Row i of the matrix A was interchanged with row IPIV(i) for i=1,2,...,min(m,n).
- 6: INFO -- INTEGER Output
On exit: INFO = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

INFO < 0

If INFO = -i, the ith parameter has an illegal value. An explanatory message is output, and execution of the program is terminated.

INFO > 0

If INFO = i, u is exactly zero. The factorization has been

ii

completed but the factor U is exactly singular, and division by zero will occur if it is subsequently used to solve a system of linear equations or to compute A^{-1} .

7. Accuracy

The computed factors L and U are the exact factors of a perturbed matrix $A+E$, where

$$|E| \leq c(\min(m,n))(\epsilon)P|L||U|,$$

$c(n)$ is a modest linear function of n , and (ϵ) is the machine precision.

8. Further Comments

The total number of floating-point operations is approximately

$$\begin{array}{lll} 2/3 & 1/2 & 1/2 \\ -n & \text{if } m=n \text{ (the usual case),} & -n(3m-n) \text{ if } m>n \text{ and } -m(3n-m) \text{ if} \\ 3 & 3 & 3 \\ m < n. \end{array}$$

A call to this routine with $m=n$ may be followed by calls to the routines:

T
F07AEF (DGETRS) to solve $AX=B$ or $A^T X=B$;
F07AGF (DGECON)(*) to estimate the condition number of A ;
F07AJF (DGETRI)(*) to compute the inverse of A .

The complex analogue of this routine is F07ARF (ZGETRF)(*).

9. Example

To compute the LU factorization of the matrix A , where

$$A = \begin{pmatrix} 1.80 & 2.88 & 2.05 & -0.89 \\ 5.25 & -2.95 & -0.95 & -3.80 \\ 1.58 & -2.69 & -2.90 & -1.04 \\ -1.11 & -0.66 & -0.59 & 0.80 \end{pmatrix}.$$

The example program is not reproduced here. The source code for

all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%

F07 -- Linear Equations (LAPACK) F07AEF
 F07AEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F07AEF (DGETRS) solves a real system of linear equations with
 $AX=B$ or $A^T X=B$, where A has been
 factorized by F07ADF (DGETRF).

2. Specification

```

      SUBROUTINE F07AEF (TRANS, N, NRHS, A, LDA, IPIV, B, LDB,
1          INFO)
      ENTRY          TRANS, N, NRHS, A, LDA, IPIV, B, LDB, INFO
      INTEGER        N, NRHS, LDA, IPIV(*), LDB, INFO
      DOUBLE PRECISION A(LDA,*), B(LDB,*)
      CHARACTER*1     TRANS
```

The ENTRY statement enables the routine to be called by its LAPACK name.

3. Description

To solve a real system of linear equations $AX=B$ or $A^T X=B$, this routine must be preceded by a call to F07ADF (DGETRF) which computes the LU factorization of A as $A=PLU$. The solution is computed by forward and backward substitution.

If TRANS = 'N', the solution is computed by solving $PLY=B$ and then $UX=Y$.

If TRANS = 'T' or 'C', the solution is computed by solving $U^T Y=B$
 $U^T X=Y$

and then $L P X=Y$.

4. References

- [1] Golub G H and Van Loan C F (1989) Matrix Computations (2nd Edition). Johns Hopkins University Press, Baltimore, Maryland.

5. Parameters

- 1: TRANS -- CHARACTER*1 Input
 On entry: indicates the form of the equations as follows:
 if TRANS = 'N', then $AX=B$ is solved for X;

T

 if TRANS = 'T' or 'C', then $A^T X=B$ is solved for X.
 Constraint: TRANS = 'N', 'T' or 'C'.
- 2: N -- INTEGER Input
 On entry: n, the order of the matrix A. Constraint: $N \geq 0$.
- 3: NRHS -- INTEGER Input
 On entry: r, the number of right-hand sides. Constraint:
 NRHS ≥ 0 .
- 4: A(LDA,*) -- DOUBLE PRECISION array Input
 Note: the second dimension of the array A must be at least
 $\max(1,N)$.
 On entry: the LU factorization of A, as returned by F07ADF
 (DGETRF).
- 5: LDA -- INTEGER Input
 On entry:
 the first dimension of the array A as declared in the
 (sub)program from which F07AEF is called.
 Constraint: $LDA \geq \max(1,N)$.
- 6: IPIV(*) -- INTEGER array Input
 Note: the dimension of the array IPIV must be at least
 $\max(1,N)$.
 On entry: the pivot indices, as returned by F07ADF (DGETRF).
- 7: B(LDB,*) -- DOUBLE PRECISION array Input/Output
 Note: the second dimension of the array B must be at least
 $\max(1,NRHS)$.
 On entry: the n by r right-hand side matrix B. On exit: the

n by r solution matrix X.

- 8: LDB -- INTEGER Input
 On entry:
 the first dimension of the array B as declared in the
 (sub)program from which F07AEF is called.
 Constraint: LDB $\geq \max(1, N)$.
- 9: INFO -- INTEGER Output
 On exit: INFO = 0 unless the routine detects an error (see
 Section 6).

6. Error Indicators and Warnings

INFO < 0

If INFO = -i, the ith parameter has an illegal value. An explanatory message is output, and execution of the program is terminated.

7. Accuracy

For each right-hand side vector b, the computed solution x is the exact solution of a perturbed system of equations $(A+E)x=b$, where

$$|E| \leq c(n)(\text{epsilon})P|L||U|,$$

$c(n)$ is a modest linear function of n, and (epsilon) is the machine precision.

If \tilde{x} is the true solution, then the computed solution x satisfies a forward error bound of the form

$$\frac{\|\tilde{x} - x\|_{\infty}}{\|x\|_{\infty}} \leq c(n) \text{cond}(A, x)(\text{epsilon})$$

$$\text{where } \text{cond}(A, x) = \frac{\|A\|_{\infty} \|x\|_{\infty}}{\|A\|_{\infty} \|x\|_{\infty}} \leq \frac{\|A\|_{\infty}}{\|A\|_{\infty} \|x\|_{\infty}}$$

$$\text{cond}(A) = \frac{\|A\|_{\infty}}{\|A\|_{\infty} \|x\|_{\infty}} \leq (\kappa) (A). \text{ Note that } \text{cond}(A, x)$$

Forward and backward error bounds can be computed by calling
F07AHF (DGERFS)(*), and an estimate for $\kappa(A)$ can be
obtained by calling F07AGF (DGECON(*) with NORM = 'I'.

The total number of floating-point operations is approximately $\frac{2}{2n+1}$.

The complex analogue of this routine is F07ASF (ZGETRS)(*).

To solve the system of equations $AX=B$, where

and

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F07 -- Linear Equations (LAPACK) F07FDF
 F07FDF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F07FDF (DPOTRF) computes the Cholesky factorization of a real symmetric positive-definite matrix.

2. Specification

```

SUBROUTINE F07FDF (UPLO, N, A, LDA, INFO)
ENTRY           UPLO, N, A, LDA, INFO
INTEGER        N, LDA, INFO
DOUBLE PRECISION A(LDA,*)
CHARACTER*1     UPLO

```

The ENTRY statement enables the routine to be called by its LAPACK name.

3. Description

This routine forms the Cholesky factorization of a real symmetric positive-definite matrix A either as $A=U^T U$ if UPLO = 'U' or $A=LL^T$ if UPLO = 'L', where U is an upper triangular matrix and L is lower triangular.

4. References

- [1] Demmel J W (1989) On Floating-point Errors in Cholesky. LAPACK Working Note No. 14. University of Tennessee, Knoxville.
- [2] Golub G H and Van Loan C F (1989) Matrix Computations (2nd Edition). Johns Hopkins University Press, Baltimore, Maryland.

5. Parameters

- 1: UPLO -- CHARACTER*1 Input
 On entry: indicates whether the upper or lower triangular

if UPLO = 'L', then the lower triangular part of A is

$$A = L^T L$$
stored and A is factorized as LL^T , where L is lower
triangular.

If INFO = i, the leading minor of order i is not positive-

definite and the factorization could not be completed. Hence A itself is not positive-definite. This may indicate an error in forming the matrix A. To factorize a symmetric matrix which is not positive-definite, call F07MDF (DSYTRF)(*) instead.

7. Accuracy

If UPL0 = 'U', the computed factor U is the exact factor of a perturbed matrix A+E, where

$$|E| \leq c(n)(\epsilon) |U|^T |U|,$$

c(n) is a modest linear function of n, and (epsilon) is the machine precision. If UPL0 = 'L', a similar statement holds for the computed factor L. It follows that

$$|e_{ij}| \leq c(n)(\epsilon) \sqrt{a_{ii} a_{jj}}.$$

8. Further Comments

The total number of floating-point operations is approximately

$$\frac{1}{3} n^3.$$

A call to this routine may be followed by calls to the routines:

F07FEF (DPOTRS) to solve AX=B;

F07FGF (DPOCON)(*) to estimate the condition number of A;

F07FJF (DPOTRI)(*) to compute the inverse of A.

The complex analogue of this routine is F07FRF (ZPOTRF)(*).

9. Example

To compute the Cholesky factorization of the matrix A, where

$$A = \begin{pmatrix} 4.16 & -3.12 & 0.56 & -0.10 \\ -3.12 & 5.03 & -0.83 & 1.18 \\ 0.56 & -0.83 & 0.76 & 0.34 \\ -0.10 & 1.18 & 0.34 & 0.56 \end{pmatrix}.$$

(-0.10 1.18 0.34 1.18)

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F07 -- Linear Equations (LAPACK) F07FEF
 F07FEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F07FEF (DPOTRS) solves a real symmetric positive-definite system of linear equations with multiple right-hand sides, $AX=B$, where A has been factorized by F07FDF (DPOTRF).

2. Specification

```
SUBROUTINE F07FEF (UPLO, N, NRHS, A, LDA, B, LDB, INFO)
  ENTRY          UPLO, N, NRHS, A, LDA, B, LDB, INFO
  INTEGER        N, NRHS, LDA, LDB, INFO
  DOUBLE PRECISION A(LDA,*), B(LDB,*)
  CHARACTER*1     UPLO
```

The ENTRY statement enables the routine to be called by its LAPACK name.

3. Description

To solve a real symmetric positive-definite system of linear equations $AX=B$, this routine must be preceded by a call to F07FDF (DPOTRF) which computes the Cholesky factorization of A . The solution X is computed by forward and backward substitution.

T

If UPLO = 'U', $A=U^T U$, where U is upper triangular; the solution X is computed by solving $U^T Y=B$ and then $UX=Y$.

T

If $UPLO = 'L'$, $A=LL^T$, where L is lower triangular; the solution X is computed by solving $LY=B$ and then $L^T X=Y$.

4. References

- [1] Golub G H and Van Loan C F (1989) Matrix Computations (2nd Edition). Johns Hopkins University Press, Baltimore, Maryland.

5. Parameters

- 1: $UPLO$ -- CHARACTER*1 Input
 On entry: indicates whether the upper or lower triangular part of A is stored and how A is factorized, as follows:

$$\text{if } UPLO = 'U', \text{ then } A=U U^T \text{ where } U \text{ is upper triangular;}$$

$$\text{if } UPLO = 'L', \text{ then } A=LL^T \text{ where } L \text{ is lower triangular.}$$
 Constraint: $UPLO = 'U'$ or $'L'$.
- 2: N -- INTEGER Input
 On entry: n , the order of the matrix A . Constraint: $N \geq 0$.
- 3: $NRHS$ -- INTEGER Input
 On entry: r , the number of right-hand sides. Constraint: $NRHS \geq 0$.
- 4: $A(LDA,*)$ -- DOUBLE PRECISION array Input
 Note: the second dimension of the array A must be at least $\max(1,N)$.
 On entry: the Cholesky factor of A , as returned by F07FDF (DPOTRF).
- 5: LDA -- INTEGER Input
 On entry:
 the first dimension of the array A as declared in the (sub)program from which F07FEF is called.
 Constraint: $LDA \geq \max(1,N)$.
- 6: $B(LDB,*)$ -- DOUBLE PRECISION array Input/Output
 Note: the second dimension of the array B must be at least $\max(1, NRHS)$.
 On entry: the n by r right-hand side matrix B .

- 7: LDB -- INTEGER Input
 On entry:
 the first dimension of the array B as declared in the
 (sub)program from which F07FEF is called.
 Constraint: LDB $\geq \max(1, N)$.
- 8: INFO -- INTEGER Output
 On exit: INFO = 0 unless the routine detects an error (see
 Section 6).

6. Error Indicators and Warnings

INFO < 0

If INFO = -i, the ith parameter has an illegal value. An explanatory message is output, and execution of the program is terminated.

7. Accuracy

For each right-hand side vector b, the computed solution x is the exact solution of a perturbed system of equations $(A+E)x=b$, where

$$|E| \leq c(n)(\epsilon) |U|^T |U| \text{ if } \text{UPLO} = 'U',$$

$$|E| \leq c(n)(\epsilon) |L|^T |L| \text{ if } \text{UPLO} = 'L',$$

$c(n)$ is a modest linear function of n , and (ϵ) is the machine precision.

\hat{x}
 If x is the true solution, then the computed solution \hat{x} satisfies a forward bound of the form

$$\frac{\|\hat{x} - x\|}{\|x\|} \leq c(n) \text{cond}(A, x)(\epsilon)$$

$$\text{where } \text{cond}(A, x) = \frac{\|A\| \|x\|}{\|Ax\|} \leq \frac{\|A\|}{\sigma_{\min}(A)}$$

$\text{cond}(A) = \frac{\|A\|_{\infty}}{\|A\|_1} \leq (\kappa)_{\infty}(A)$. Note that $\text{cond}(A, x)$ can be much smaller than $\text{cond}(A)$.

Forward and backward error bounds can be computed by calling F07FHF (DPORFS)(*), and an estimate for $(\kappa)_{\infty}(A)$ ($= (\kappa)_{\infty}(A)$) can be obtained by calling F07FGF (DPOCON)(*).

1

8. Further Comments

The total number of floating-point operations is approximately $2n^2$.

This routine may be followed by a call to F07FHF (DPORFS)(*), to refine the solution and return an error estimate.

The complex analogue of this routine is F07FSF (ZPOTRS)(*).

9. Example

To compute the Cholesky factorization of the matrix A, where

$$A = \begin{pmatrix} 4.16 & -3.12 & 0.56 & -0.10 \\ -3.12 & 5.03 & -0.83 & 1.18 \\ 0.56 & -0.83 & 0.76 & 0.34 \\ -0.10 & 1.18 & 0.34 & 1.18 \end{pmatrix}.$$

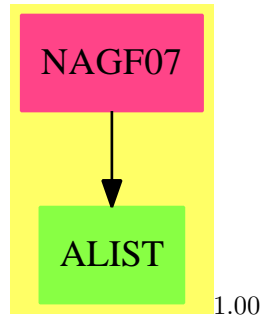

and

$$B = \begin{pmatrix} 8.70 & 8.30 \\ -13.35 & 2.13 \\ 1.89 & 1.61 \\ -4.14 & 5.00 \end{pmatrix}.$$

Here A is symmetric positive-definite and must first be factorized by F07FDF (DPOTRF).

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F01 -- Matrix Factorization

Introduction -- F01

Chapter F01

Matrix Factorization

1. Scope of the Chapter

This chapter provides facilities for matrix factorizations and associated transformations.

2. Background to the Problems

An n by n matrix may be factorized as

$$A = PLUQ^T,$$

where L and U are respectively lower and upper triangular matrices, and P and Q are permutation matrices. This is called an LU factorization. For general dense matrices it is usual to choose $Q=I$ and to then choose P to ensure that the factorization is numerically stable. For sparse matrices, judicious choice of P and Q ensures numerical stability as well as maintaining as much sparsity as possible in the factors L and U . The LU factorization is normally used in connection with the solution of the linear equations

$$Ax=b,$$

whose solution, x , may then be obtained by solving in succession the simpler equations

$$L^T y = P^T b, \quad U z = y, \quad x = Q z$$

the first by forward substitution and the second by backward substitution. Routines to perform this solution are to be found in Chapter F04.

When A is symmetric positive-definite then we can choose $U=L$ and $Q=P$, to give the Cholesky factorization. This factorization is numerically stable without permutations, but in the sparse case the permutations can again be used to try to maintain sparsity. The Cholesky factorization is sometimes expressed as

$$A = PLDL^T P^T,$$

where D is a diagonal matrix with positive diagonal elements and L is unit lower triangular.

The LU factorization can also be performed on rectangular matrices, but in this case it is more usual to perform a QR factorization. When A is an m by n ($m \geq n$) matrix this is given by

$$A = QR,$$

where R is an n by n upper triangular matrix and Q is an orthogonal (unitary in the complex case) matrix.

3. Recommendations on Choice and Use of Routines

Routine F07ADF performs the LU factorization of a real m by n dense matrix.

The LU factorization of a sparse matrix is performed by routine F01BRF. Following the use of F01BRF, matrices with the same sparsity pattern may be factorized by routine F01BSF.

The Cholesky factorization of a real symmetric positive-definite dense matrix is performed by routine F07FDF.

Routine F01MCF performs the Cholesky factorization of a real symmetric positive-definite variable band (skyline) matrix, and a general sparse symmetric positive-definite matrix may be factorized using routine F01MAF.

The QR factorization of an m by n ($m \geq n$) matrix is performed by routine F01QCF in the real case, and F01RCF in the complex case. Following the use of F01QCF, operations with Q may be performed using routine F01QDF and some, or all, of the columns of Q may be formed using routine F01QEF. Routines F01RDF and F01REF perform the same tasks following the use of F01RCF.

F01 -- Matrix Factorizations

F01BRF

F01BRF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for
your implementation to check implementation-dependent details.
The symbol (*) after a NAG routine name denotes a routine that is

not included in the Foundation Library.

1. Purpose

F01BRF factorizes a real sparse matrix. The routine either forms the LU factorization of a permutation of the entire matrix, or, optionally, first permutes the matrix to block lower triangular form and then only factorizes the diagonal blocks.

2. Specification

```

      SUBROUTINE F01BRF (N, NZ, A, LICN, IRN, LIRN, ICN, PIVOT,
1      IKEEP, IW, W, LBLOCK, GROW, ABORT,
2      IDISP, IFAIL)
      INTEGER      N, NZ, LICN, IRN(LIRN), LIRN, ICN(LICN),
1      IKEEP(5*N), IW(8*N), IDISP(10), IFAIL
      DOUBLE PRECISION A(LICN), PIVOT, W(N)
      LOGICAL      LBLOCK, GROW, ABORT(4)

```

3. Description

Given a real sparse matrix A, this routine may be used to obtain the LU factorization of a permutation of A,

$$PAQ=LU$$

where P and Q are permutation matrices, L is unit lower triangular and U is upper triangular. The routine uses a sparse variant of Gaussian elimination, and the pivotal strategy is designed to compromise between maintaining sparsity and controlling loss of accuracy through round-off.

Optionally the routine first permutes the matrix into block lower triangular form and then only factorizes the diagonal blocks. For some matrices this gives a considerable saving in storage and execution time.

Extensive data checks are made; duplicated non-zeros can be accumulated.

The factorization is intended to be used by F04AXF to solve

$$T$$
sparse systems of linear equations $Ax=b$ or $A^T x=b$. If several matrices of the same sparsity pattern are to be factorized, F01BSF should be used for the second and subsequent matrices.

The method is fully described by Duff [1].

4. References

- [1] Duff I S (1977) MA28 -- a set of Fortran subroutines for sparse unsymmetric linear equations. A.E.R.E. Report R.8730. HMSO.

5. Parameters

- 1: N -- INTEGER Input
On entry: n, the order of the matrix A. Constraint: $N > 0$.
- 2: NZ -- INTEGER Input
On entry: the number of non-zero elements in the matrix A. Constraint: $NZ > 0$.
- 3: A(LICN) -- DOUBLE PRECISION array Input/Output
On entry: A(i), for $i = 1, 2, \dots, NZ$ must contain the non-zero elements of the sparse matrix A. They can be in any order since the routine will reorder them. On exit: the non-zero elements in the LU factorization. The array must not be changed by the user between a call of this routine and a call of F04AXF.
- 4: LICN -- INTEGER Input
On entry:
the dimension of the arrays A and ICN as declared in the (sub)program from which F01BRF is called.
Since the factorization is returned in A and ICN, LICN should be large enough to accommodate this and should ordinarily be 2 to 4 times as large as NZ. Constraint: $LICN \geq NZ$.
- 5: IRN(LIRN) -- INTEGER array Input/Output
On entry: IRN(i), for $i = 1, 2, \dots, NZ$ must contain the row index of the non-zero element stored in A(i). On exit: the array is overwritten and is not needed for subsequent calls of F01BSF or F04AXF.
- 6: LIRN -- INTEGER Input
On entry:
the dimension of the array IRN as declared in the (sub)program from which F01BRF is called.
It need not be as large as LICN; normally it will not need to be very much greater than NZ. Constraint: $LIRN \geq NZ$.

- 7: ICN(LICN) -- INTEGER array Input/Output
 On entry: ICN(i), for $i = 1, 2, \dots, NZ$ must contain the column index of the non-zero element stored in A(i). On exit: the column indices of the non-zero elements in the factorization. The array must not be changed by the user between a call of this routine and subsequent calls of F01BSF or F04AXF.
- 8: PIVOT -- DOUBLE PRECISION Input
 On entry: PIVOT should have a value in the range $0.0 \leq \text{PIVOT} \leq 0.9999$ and is used to control the choice of pivots. If $\text{PIVOT} < 0.0$, the value 0.0 is assumed, and if $\text{PIVOT} > 0.9999$, the value 0.9999 is assumed. When searching a row for a pivot, any element is excluded which is less than PIVOT times the largest of those elements in the row available as pivots. Thus decreasing PIVOT biases the algorithm to maintaining sparsity at the expense of stability. Suggested value: $\text{PIVOT} = 0.1$ has been found to work well on test examples.
- 9: IKEEP(5*N) -- INTEGER array Output
 On exit: indexing information about the factorization. The array must not be changed by the user between a call of this routine and calls of F01BSF or F04AXF.
- 10: IW(8*N) -- INTEGER array Workspace
- 11: W(N) -- DOUBLE PRECISION array Output
 On exit: if $\text{GROW} = \text{.TRUE.}$, W(1) contains an estimate (an upper bound) of the increase in size of elements encountered during the factorization (see GROW); the rest of the array is used as workspace.

 If $\text{GROW} = \text{.FALSE.}$, the array is not used.
- 12: LBLOCK -- LOGICAL Input
 On entry: if $\text{LBLOCK} = \text{.TRUE.}$, the matrix is pre-ordered into block lower triangular form before the LU factorization is performed; otherwise the entire matrix is factorized. Suggested value: $\text{LBLOCK} = \text{.TRUE.}$ unless the matrix is known to be irreducible.
- 13: GROW -- LOGICAL Input
 On entry: if $\text{GROW} = \text{.TRUE.}$, then on exit W(1) contains an estimate (an upper bound) of the increase in size of

elements encountered during the factorization. If the matrix is well-scaled (see Section 8.2), then a high value for W(1) indicates that the LU factorization may be inaccurate and the user should be wary of the results and perhaps increase the parameter PIVOT for subsequent runs (see Section 7). Suggested value: GROW = .TRUE..

14: ABORT(4) -- LOGICAL array Input

On entry:

if ABORT(1) = .TRUE., the routine will exit immediately on detecting a structural singularity (one that depends on the pattern of non-zeros) and return

IFAIL = 1; otherwise it will complete the factorization (see Section 8.3).

If ABORT(2) = .TRUE., the routine will exit immediately on detecting a numerical singularity (one that depends on the numerical values) and return IFAIL = 2; otherwise it will complete the factorization (see Section 8.3).

If ABORT(3) = .TRUE., the routine will exit immediately (with IFAIL = 5) when the arrays A and ICN are filled up by the previously factorized, active and unfactorized parts of the matrix; otherwise it continues so that better guidance on necessary array sizes can be given in IDISP(6) and IDISP(7), and will exit with IFAIL in the range 4 to 6. Note that there is always an immediate error exit if the array IRN is too small.

If ABORT(4) = .TRUE., the routine exits immediately (with IFAIL = 13) if it finds duplicate elements in the input matrix. If ABORT(4) = .FALSE., the routine proceeds using a value equal to the sum of the duplicate elements. In either case details of each duplicate element are output on the current advisory message unit (see X04ABF), unless suppressed by the value of IFAIL on entry.

Suggested values:

ABORT(1) = .TRUE.

ABORT(2) = .TRUE.

ABORT(3) = .FALSE.

ABORT(4) = .TRUE..

- 15: IDISP(10) -- INTEGER array Output
 On exit: IDISP is used to communicate information about the factorization to the user and also between a call of F01BRF and subsequent calls to F01BSF or F04AXF.

IDISP(1) and IDISP(2), indicate the position in arrays A and ICN of the first and last elements in the LU factorization of the diagonal blocks. (IDISP(2) gives the number of non-zeros in the factorization.)

IDISP(3) and IDISP(4), monitor the adequacy of 'elbow room' in the arrays IRN and A/ICN respectively, by giving the number of times that the data in these arrays has been compressed during the factorization to release more storage. If either IDISP(3) or IDISP(4) is quite large (say greater than 10), it will probably pay the user to increase the size of the corresponding array(s) for subsequent runs. If either is very low or zero, then the user can perhaps save storage by reducing the size of the corresponding array(s).

IDISP(5), gives an upper bound on the rank of the matrix.

IDISP(6) and IDISP(7), give the minimum size of arrays IRN and A/ICN respectively which would enable a successful run on an identical matrix (but some 'elbow-room' should be allowed - see Section 8).

IDISP(8) to (10), are only used if LBLOCK = .TRUE..

IDISP(8), gives the structural rank of the matrix.

IDISP(9), gives the number of diagonal blocks.

IDISP(10), gives the size of the largest diagonal block.

IDISP(1) and IDISP(2), must not be changed by the user between a call of F01BRF and subsequent calls to F01BSF or F04AXF.

- 16: IFAIL -- INTEGER Input/Output
 For this routine, the normal use of IFAIL is extended to

control the printing of error and warning messages as well as specifying hard or soft failure (see the Essential Introduction).

Before entry, IFAIL must be set to a value with the decimal expansion cba , where each of the decimal digits c , b and a must have a value of 0 or 1.

$a=0$ specifies hard failure, otherwise soft failure;

$b=0$ suppresses error messages, otherwise error messages will be printed (see Section 6);

$c=0$ suppresses warning messages, otherwise warning messages will be printed (see Section 6).

The recommended value for inexperienced users is 110 (i.e., hard failure with all messages printed).

Unless the routine detects an error (see Section 6), IFAIL contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

For each error, an explanatory error message is output on the current error message unit (as defined by X04AAF), unless suppressed by the value of IFAIL on entry.

IFAIL=-2

Successful factorization of a numerically singular matrix (which may also be structurally singular) (see Section 8.3).

IFAIL=-1

Successful factorization of a structurally singular matrix (see Section 8.3).

IFAIL= 1

The matrix is structurally singular and the factorization has been abandoned (ABORT(1) was .TRUE. on entry).

IFAIL= 2

The matrix is numerically singular and the factorization has been abandoned (ABORT(2) was .TRUE. on entry).

IFAIL= 3

LIRN is too small: there is not enough space in the array

IRN to continue the factorization. The user is recommended to try again with LIRN (and the length of IRN) equal to at least IDISP(6) + N/2.

IFAIL= 4

LICN is much too small: there is much too little space in the arrays A and ICN to continue the factorization.

IFAIL= 5

LICN is too small: there is not enough space in the arrays A and ICN to store the factorization. If ABORT(3) was .FALSE. on entry, the factorization has been completed but some of the LU factors have been discarded to create space, IDISP(7) then gives the minimum value of LICN (i.e., the minimum length of A and ICN) required for a successful factorization of the same matrix.

IFAIL= 6

LICN and LIRN are both too small: effectively this is a combination of IFAIL = 3 and IFAIL = 5 (with ABORT(3) = .FALSE.).

IFAIL= 7

LICN is too small: there is not enough space in the arrays A and ICN for the permutation to block triangular form.

IFAIL= 8

On entry N <= 0.

IFAIL= 9

On entry NZ <= 0.

IFAIL= 10

On entry LICN < NZ.

IFAIL= 11

On entry LIRN < NZ.

IFAIL= 12

On entry an element of the input matrix has a row or column index (i.e., an element of IRN or ICN) outside the range 1 to N.

IFAIL= 13

Duplicate elements have been found in the input matrix and the factorization has been abandoned (ABORT(4) = .TRUE. on

entry).

7. Accuracy

The factorization obtained is exact for a perturbed matrix whose (i,j)th element differs from a_{ij} by less than $3(\text{epsilon})(\rho)m_{ij}$

where (epsilon) is the machine precision, (rho) is the growth value returned in W(1) if GROW = .TRUE., and m_{ij} the number of Gaussian elimination operations applied to element (i,j). The

value of m_{ij} is not greater than n and is usually much less.

Small (rho) values therefore guarantee accurate results, but unfortunately large (rho) values may give a very pessimistic indication of accuracy.

8. Further Comments

8.1. Timing

The time required may be estimated very roughly from the number (tau) of non-zeros in the factorized form (output as IDISP(2)) and for this routine and its associates is

$$F01BRF: 5(\tau)^2 / n \text{ units}$$

$$F01BSF: (\tau)^2 / n \text{ units}$$

$$F04AXF: 2(\tau) \text{ units}$$

where our unit is the time for the inner loop of a full matrix

code (e.g. solving a full set of equations takes about $\frac{1}{3}n^3$ units). Note that the faster F01BSF time makes it well worthwhile to use this for a sequence of problems with the same pattern.

It should be appreciated that (tau) varies widely from problem to problem. For network problems it may be little greater than NZ, the number of non-zeros in A; for discretisation of 2-dimensional and 3-dimensional partial differential equations it may be about

$\frac{1}{3}n^{5/3}$ and $\frac{1}{3}n^2$, respectively.

2 2

The time taken to find the block lower triangular form (LBLOCK = it is not found (LBLOCK = .FALSE.). If the matrix is irreducible (IDISP(9) = 1 after a call with LBLOCK = .TRUE.) then this time is wasted. Otherwise, particularly if the largest block is small (IDISP(10)<n), the consequent savings are likely to be greater.

The time taken to estimate growth (GROW = .TRUE.) is typically under 2% of the overall time.

The overall time may be substantially increased if there is inadequate 'elbow-room' in the arrays A, IRN and ICN. When the sizes of the arrays are minimal (IDISP(6) and IDISP(7)) it can execute as much as three times slower. Values of IDISP(3) and IDISP(4) greater than about 10 indicate that it may be worthwhile to increase array sizes.

8.2. Scaling

The use of a relative pivot tolerance PIVOT essentially presupposes that the matrix is well-scaled, i.e., that the matrix elements are broadly comparable in size. Practical problems are often naturally well-scaled but particular care is needed for problems containing mixed types of variables (for example millimetres and neutron fluxes).

8.3. Singular and Rectangular Systems

It is envisaged that this routine will almost always be called for square non-singular matrices and that singularity indicates an error condition. However, even if the matrix is singular it is possible to complete the factorization. It is even possible for F04AXF to solve a set of equations whose matrix is singular provided the set is consistent.

Two forms of singularity are possible. If the matrix would be singular for any values of the non-zeros (e.g. if it has a whole row of zeros), then we say it is structurally singular, and continue only if ABORT(1) = .FALSE.. If the matrix is non-singular by virtue of the particular values of the non-zeros, then we say that it is numerically singular and continue only if ABORT(2) = .FALSE..

Rectangular matrices may be treated by setting N to the larger of the number of rows and numbers of columns and setting ABORT(1) =

Note: the soft failure option should be used (last digit of IFAIL = 1) if the user wishes to factorize singular matrices with ABORT(1) or ABORT(2) set to .FALSE..

8.4. Duplicated Non-zeros

The matrix A may consist of a sum of contributions from different sub-systems (for example finite elements). In such cases the user may rely on this routine to perform assembly, since duplicated elements are summed.

9. Example

To factorize the real sparse matrix:

```
( 5  0  0  0  0  0)
( 0  2 -1  2  0  0)
( 0  0  3  0  0  0)
(-2  0  0  1  1  0).
(-1  0  0 -1  2 -3)
(-1 -1  0  0  0  6)
```

This example program simply prints out some information about the factorization as returned by F01BRF in W(1) and IDISP. Normally the call of F01BRF would be followed by a call of F04AXF (see Example for F04AXF).

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F01 -- Matrix Factorizations

F01BSF

F01BSF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F01BSF factorizes a real sparse matrix using the pivotal sequence previously obtained by F01BRF when a matrix of the same sparsity

pattern was factorized.

2. Specification

```

SUBROUTINE F01BSF (N, NZ, A, LICN, IVECT, JVECT, ICN,
1                IKEEP, IW, W, GROW, ETA, RPMIN, ABORT,
2                IDISP, IFAIL)
  INTEGER        N, NZ, LICN, IVECT(NZ), JVECT(NZ), ICN
1                (LICN), IKEEP(5*N), IW(8*N), IDISP(2),
2                IFAIL
  DOUBLE PRECISION A(LICN), W(N), ETA, RPMIN
  LOGICAL        GROW, ABORT

```

3. Description

This routine accepts as input a real sparse matrix of the same sparsity pattern as a matrix previously factorized by a call of F01BRF. It first applies to the matrix the same permutations as were used by F01BRF, both for permutation to block triangular form and for pivoting, and then performs Gaussian elimination to obtain the LU factorization of the diagonal blocks.

Extensive data checks are made; duplicated non-zeros can be accumulated.

The factorization is intended to be used by F04AXF to solve

$$T$$
sparse systems of linear equations $Ax=b$ or $A^T x=b$.

F01BSF is much faster than F01BRF and in some applications it is expected that there will be many calls of F01BSF for each call of F01BRF.

The method is fully described in Duff [1].

4. References

- [1] Duff I S (1977) MA28 -- a set of Fortran subroutines for sparse unsymmetric linear equations. A.E.R.E. Report R.8730. HMSO.

5. Parameters

1: N -- INTEGER Input
 On entry: n, the order of the matrix A. Constraint: N > 0.

- 2: NZ -- INTEGER Input
 On entry: the number of non-zeros in the matrix A.
 Constraint: NZ > 0.

- 3: A(LICN) -- DOUBLE PRECISION array Input/Output
 On entry: A(i), for i = 1,2,...,NZ must contain the non-zero elements of the sparse matrix A. They can be in any order since the routine will reorder them. On exit: the non-zero elements in the factorization. The array must not be changed by the user between a call of this routine and a call of F04AXF.

- 4: LICN -- INTEGER Input
 On entry:
 the dimension of the arrays A and ICN as declared in the (sub)program from which F01BSF is called.
 It should have the same value as it had for F01BRF.
 Constraint: LICN >= NZ.

- 5: IVECT(NZ) -- INTEGER array Input

- 6: JVECT(NZ) -- INTEGER array Input
 On entry: IVECT(i) and JVECT(i), for i = 1,2,...,NZ must contain the row index and the column index respectively of the non-zero element stored in A(i).

- 7: ICN(LICN) -- INTEGER array Input
 On entry: the same information as output by F01BRF. It must not be changed by the user between a call of this routine and a call of F04AXF.

- 8: IKEEP(5*N) -- INTEGER array Input
 On entry: the same indexing information about the factorization as output from F01BRF. It must not be changed between a call of this routine and a call of F04AXF.

- 9: IW(8*N) -- INTEGER array Workspace

- 10: W(N) -- DOUBLE PRECISION array Output
 On exit: if GROW = .TRUE., W(1) contains an estimate (an upper bound) of the increase in size of elements encountered during the factorization (see GROW); the rest of the array is used as workspace.

 If GROW = .FALSE., the array is not used.

- 11: GROW -- LOGICAL Input
 On entry: if GROW = .TRUE., then on exit W(1) contains an estimate (an upper bound) of the increase in size of elements encountered during the factorization. If the matrix is well-scaled (see Section 8.2), then a high value for W(1) indicates that the LU factorization may be inaccurate and the user should be wary of the results and perhaps increase the parameter PIVOT for subsequent runs (see Section 7).
- 12: ETA -- DOUBLE PRECISION Input
 On entry: the relative pivot threshold below which an error diagnostic is provoked and IFAIL is set to 7. If ETA is greater than 1.0, then no check on pivot size is made.
-4
 Suggested value: ETA = 10 .
- 13: RPMIN -- DOUBLE PRECISION Output
 On exit: if ETA is less than 1.0, then RPMIN gives the smallest ratio of the pivot to the largest element in the row of the corresponding upper triangular factor thus monitoring the stability of the factorization. If RPMIN is very small it may be advisable to perform a new factorization using F01BRF.
- 14: ABORT -- LOGICAL Input
 On entry: if ABORT = .TRUE., the routine exits immediately (with IFAIL = 8) if it finds duplicate elements in the input matrix. If ABORT = .FALSE., the routine proceeds using a value equal to the sum of the duplicate elements. In either case details of each duplicate element are output on the current advisory message unit (see X04ABF), unless suppressed by the value of IFAIL on entry. Suggested value: ABORT = .TRUE..
- 15: IDISP(2) -- INTEGER array Input
 On entry: IDISP(1) and IDISP(2) must be unchanged since the previous call of F01BRF.
- 16: IFAIL -- INTEGER Input/Output
 For this routine, the normal use of IFAIL is extended to control the printing of error and warning messages as well as specifying hard or soft failure (see the Essential Introduction).

Before entry, IFAIL must be set to a value with the decimal expansion cba, where each of the decimal digits c, b and a

must have a value of 0 or 1.

a=0 specifies hard failure, otherwise soft failure;

b=0 suppresses error messages, otherwise error messages will be printed (see Section 6);

c=0 suppresses warning messages, otherwise warning messages will be printed (see Section 6).

The recommended value for inexperienced users is 110 (i.e., hard failure with all messages printed).

Unless the routine detects an error (see Section 6), IFAIL contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

For each error, an explanatory error message is output on the current error message unit (as defined by X04AAF), unless suppressed by the value of IFAIL on entry.

IFAIL= 1

On entry $N \leq 0$.

IFAIL= 2

On entry $NZ \leq 0$.

IFAIL= 3

On entry $LICN < NZ$.

IFAIL= 4

On entry an element of the input matrix has a row or column index (i.e., an element of IVECT or JVECT) outside the range 1 to N.

IFAIL= 5

The input matrix is incompatible with the matrix factorized by the previous call of F01BRF (see Section 8).

IFAIL= 6

The input matrix is numerically singular.

IFAIL= 7

A very small pivot has been detected (see Section 5, ETA). The factorization has been completed but is potentially

unstable.

IFAIL= 8

Duplicate elements have been found in the input matrix and the factorization has been abandoned (ABORT = .TRUE. on entry).

7. Accuracy

The factorization obtained is exact for a perturbed matrix whose (i,j)th element differs from a_{ij} by less than $3(\text{epsilon})(\rho)m_{ij}$ where (epsilon) is the machine precision, (rho) is the growth value returned in W(1) if GROW = .TRUE., and m_{ij} the number of Gaussian elimination operations applied to element (i,j).

If (rho) = W(1) is very large or RPMIN is very small, then a fresh call of F01BRF is recommended.

8. Further Comments

If the user has a sequence of problems with the same sparsity pattern then this routine is recommended after F01BRF has been called for one such problem. It is typically 4 to 7 times faster but is potentially unstable since the previous pivotal sequence is used. Further details on timing are given in document F01BRF.

If growth estimation is performed (GROW = .TRUE.), then the time increases by between 5% and 10%. Pivot size monitoring (ETA <= 1.0) involves a similar overhead.

We normally expect this routine to be entered with a matrix having the same pattern of non-zeros as was earlier presented to F01BRF. However there is no record of this pattern, but rather a record of the pattern including all fill-ins. Therefore we permit additional non-zeros in positions corresponding to fill-ins.

If singular matrices are being treated then it is also required that the present matrix be sufficiently like the previous one for the same permutations to be suitable for factorization with the same set of zero pivots.

9. Example

To factorize the real sparse matrices

```

( 5  0  0  0  0  0)
( 0  2 -1  2  0  0)
( 0  0  3  0  0  0)
(-2  0  0  1  1  0)
(-1  0  0 -1  2 -3)
(-1 -1  0  0  0  6)

```

and

```

(10  0  0  0  0  0)
( 0 12 -3 -1  0  0)
( 0  0 15  0  0  0)
(-2  0  0 10 -1  0).
(-1  0  0 -5  1 -1)
(-1 -2  0  0  0  6)

```

This example program simply prints the values of $W(1)$ and $RPMIN$ returned by `F01BSF`. Normally the calls of `F01BRF` and `F01BSF` would be followed by calls of `F04AXF`.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F01 -- Matrix Factorizations

F01MAF

F01MAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F01MAF computes an incomplete Cholesky factorization of a real sparse symmetric positive-definite matrix A .

2. Specification

```

SUBROUTINE F01MAF (N, NZ, A, LICN, IRN, LIRN, ICN, DROPTL,
1                DENSW, WKEEP, IKEEP, IWORK, ABORT,
2                INFORM, IFAIL)
INTEGER          N, NZ, LICN, IRN(LIRN), LIRN, ICN(LICN),

```

```

1          IKEEP(2*N), IWORK(6*N), INFORM(4), IFAIL
DOUBLE PRECISION A(LICN), DROPTL, DENSU, WKEEP(3*N)
LOGICAL        ABORT(3)

```

3. Description

F01MAF computes an incomplete Cholesky factorization

$$C = PL^T D L^T P^T, \quad WAW = C + E$$

for the sparse symmetric positive-definite matrix A, where P is a permutation matrix, L is a unit lower triangular matrix, D is a diagonal matrix with positive diagonal elements, E is an error matrix representing elements dropped during the factorization and diagonal elements that have been modified to ensure that C is positive-definite, and W is a diagonal matrix, chosen to make the diagonal elements of WAW unity.

$W^{-1} C W^{-1}$ is a pre-conditioning matrix for A, and the factorization of C is intended to be used by F04MAF to solve systems of linear equations $Ax=b$.

The permutation matrix P is chosen to reduce the amount of fill-in that occurs in L and the user-supplied parameter DROPTL can also be used to control the amount of fill-in that occurs.

Full details on the factorization can be found in Munksgaard [1].

F01MAF is based on the Harwell Library routine MA31A.

4. References

- [1] Munksgaard N (1980) Solving Sparse Symmetric Sets of Linear Equations by Pre-conditioned Conjugate Gradients. ACM Trans. Math. Softw. 6 206--219.

5. Parameters

- 1: N -- INTEGER Input
On entry: n, the order of the matrix A. Constraint: N >= 1.
- 2: NZ -- INTEGER Input
On entry: the number of non-zero elements in the upper triangular part of the matrix A, including the number of

elements on the leading diagonal. Constraint: $NZ \geq N$.

- 3: A(LICN) -- DOUBLE PRECISION array Input/Output
 On entry: the first NZ elements of the array A must contain the non-zero elements of the upper triangular part of the sparse positive-definite symmetric matrix A, including the elements on the leading diagonal. On exit: the first (NZ-N) elements of A contain the elements above the diagonal of the matrix WAW, where W is a diagonal matrix whose i th diagonal element is $w = a_{ii}^{-1/2}$. These elements are returned in order by rows and the value returned in ICN(k) gives the column index of the element returned in A(k). The value w_i is returned in the i th element of the array WKEEP. The remaining LROW-NZ+N elements of A, where LROW is the value returned in INFORM(1), return details of the factorization for use by F04MAF.
- 4: LICN -- INTEGER Input
 On entry:
 the dimension of the array A as declared in the (sub)program from which F01MAF is called.
 If fill-in is expected during the factorization, then a larger value of LICN will allow fewer elements to be dropped during the factorization, thus giving a more accurate factorization, which in turn will almost certainly mean that fewer iterations will be required by F04MAF. Constraint: $LICN \geq 2 * NZ$.
- 5: IRN(LIRN) -- INTEGER array Input/Output
 On entry: IRN(k), for $k = 1, 2, \dots, NZ$ must contain the row index of the non-zero element of the matrix A supplied in A(k). On exit: the first LCOL elements of IRN, where LCOL is the value returned in INFORM(2), return details of the factorization for use by F04MAF.
- 6: LIRN -- INTEGER Input
 On entry:
 the dimension of the array IRN as declared in the (sub)program from which F01MAF is called.
 LIRN must be at least NZ, but, as with LICN, if fill-in is expected then a larger value of LIRN will allow a more accurate factorization. For this purpose LIRN should exceed NZ by the same amount that LICN exceeds $2 * NZ$. Constraint: $LIRN \geq NZ$.

7: ICN(LICN) -- INTEGER array Input/Output
 On entry: ICN(k), for $k = 1, 2, \dots, NZ$ must contain the column index of the non-zero element of the matrix A supplied in A(k). Thus $a_{ij} = A(k)$, where $i = IRN(k)$ and $j = ICN(k)$. On exit: the first (NZ-N) elements of ICN give the column indices of the first (NZ-N) elements returned in A. The remaining LROW - NZ + N elements of ICN return details of the factorization for use by F04MAF.

8: DROPTL -- DOUBLE PRECISION Input/Output
 On entry: a value in the range $[-1.0, 1.0]$ to be used as a tolerance in deciding whether or not to drop elements during the factorization. At the kth pivot step the element $a_{ij}^{(k+1)}$ is dropped if it would cause fill-in and if

$$|a_{ij}^{(k+1)}| < |DROPTL| * \sqrt{a_{ii}^{(k)} a_{jj}^{(k)}}.$$

If DROPTL is supplied as negative, then it is not altered during the factorization and so is unchanged on exit, but if DROPTL is supplied as positive then it may be altered by the routine with the aim of obtaining an accurate factorization in the space available. If DROPTL is supplied as -1.0, then no fill-in will occur during the factorization; and if DROPTL is supplied as 0.0 then a complete factorization is performed. On exit: may be overwritten with the value used by the routine in order to obtain an accurate factorization in the space available, if $DROPTL > 0.0$ on entry.

9: DENSW -- DOUBLE PRECISION Input/Output
 On entry: a value in the range $[0.0, 1.0]$ to be used in deciding whether or not to regard the active part of the matrix at the kth pivot step as being full. If the ratio of non-zero elements to the total number of elements is greater than or equal to DENSW, then the active part is regarded as full. If $DENSW < 1.0$, then the storage used is likely to increase compared to the case where $DENSW = 0$, but the execution time is likely to decrease. Suggested value: $DENSW = 0.8$. On exit: if on entry DENSW is not in the range $[0.0, 1.0]$, then it is set to 0.8. Otherwise it is unchanged.

- 10: WKEEP(3*N) -- DOUBLE PRECISION array Output
 On exit: information which must be passed unchanged to
 FO4MAF. The first N elements contain the values w_i , for
 $i=1,2,\dots,n$, and the next N elements contain the diagonal
 elements of D.
- 11: IKEEP(2*N) -- INTEGER array Output
 On exit: information which must be passed unchanged to
 FO4MAF.
- 12: IWORK(6*N) -- INTEGER array Workspace
- 13: ABORT(3) -- LOGICAL array Input
 On entry:
 if ABORT(1) = .TRUE., the routine will exit
 immediately on detecting duplicate elements and return
 IFAIL = 5. Otherwise when ABORT(1) = .FALSE., the
 calculations will continue using the sum of the
 duplicate entries. In either case details of the
 duplicate elements are output on the current advisory
 message unit (see X04ABF), unless suppressed by the
 value of IFAIL on entry.
- If ABORT(2) = .TRUE., the routine will exit
 immediately on detecting a zero or negative pivot
 element and return IFAIL = 6. Otherwise when ABORT(2)
 = .FALSE., the zero or negative pivot element will be
 modified to ensure positive-definiteness and a message
 will be printed on the current advisory message unit,
 unless suppressed by the value of IFAIL on entry.
- If ABORT(3) = .TRUE., the routine will exit
 immediately if the arrays A and ICN have been filled
 up and return IFAIL = 7. Otherwise when ABORT(3) = .
 FALSE., the data in the arrays is compressed to
 release more storage and a message will be printed on
 the current advisory message unit, unless suppressed
 by the value of IFAIL on entry. If DROPTL is positive
 on entry, it may be modified in order to allow a
 factorization to be completed in the available space.
- Suggested values:
 ABORT(1) = .TRUE.,
 ABORT(2) = .TRUE.,

ABORT(3) = .TRUE..

14: INFORM(4) -- INTEGER array Output

On exit:

INFORM(1) returns the number of elements of A and ICN that have been used by the routine. Thus at least the first INFORM(1) elements of A and of ICN must be supplied to F04MAF.

Similarly, INFORM(2) returns the number of elements of IRN that have been used by the routine and so at least the first INFORM(2) elements must be supplied to F04MAF.

INFORM(3) returns the number of entries supplied in A that corresponded to diagonal and duplicate elements. If no duplicate entries were found, then INFORM(3) will return the value of N.

INFORM(4) returns the value k of the pivot step from which the active matrix was regarded as full. INFORM must be passed unchanged to F04MAF.

15: IFAIL -- INTEGER Input/Output

For this routine, the normal use of IFAIL is extended to control the printing of error and warning messages as well as specifying hard or soft failure (see the Essential Introduction).

Before entry, IFAIL must be set to a value with the decimal expansion cba, where each of the decimal digits c, b and a must have a value of 0 or 1.

a=0 specifies hard failure, otherwise soft failure;

b=0 suppresses error messages, otherwise error messages will be printed (see Section 6);

c=0 suppresses warning messages, otherwise warning messages will be printed (see Section 6).

The recommended value for inexperienced users is 110 (i.e., hard failure with all messages printed).

Unless the routine detects an error (see Section 6), IFAIL contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

For each error, an explanatory error message is output on the current error message unit (as defined by X04AAF), unless suppressed by the value of IFAIL on entry.

IFAIL= 1

On entry $N < 1$,

or $NZ < N$,

or $LIRN < NZ$,

or $LICN < 2 * NZ$.

IFAIL= 2

One of the conditions $0 < IRN(k) \leq ICN(k) \leq N$ is not satisfied so that $A(k)$ is not in the upper triangle of the matrix. No further computation is attempted.

IFAIL= 3

One of the diagonal elements of the matrix A is zero or negative so that A is not positive-definite. No further computation is attempted.

IFAIL= 4

The available space has been used and no further compressions are possible. The user should either increase DROPTL, or allocate more space to A , IRN and ICN .

For all the remaining values of IFAIL the computations will continue in the case of soft failure, so that more than one advisory message may be printed.

IFAIL= 5

Duplicate elements have been detected and $ABORT(1) = .TRUE..$

IFAIL= 6

A zero or negative pivot element has been detected during the factorization and $ABORT(2) = .TRUE..$

This should not happen if A is an M -matrix (see Munksgaard [1]), but may occur for other types of positive-definite matrix.

IFAIL= 7

The available space has been used and ABORT(3) = .TRUE..

7. Accuracy

The accuracy of the factorization will be determined by the size of the elements that are dropped and the size of the modifications made to the diagonal elements. If these sizes are small then the computed factors will correspond to a matrix close to A and the number of iterations required by F04MAF will be small. The more incomplete the factorization, the higher the number of iterations required by F04MAF.

8. Further Comments

The time taken by the routine will depend upon the sparsity pattern of the matrix and the number of fill-ins that occur during the factorization. At the very least the time taken can be expected to be roughly proportional to $n(\tau)$, where (τ) is the number of non-zeros.

The routine is intended for use with positive-definite matrices, but the user is warned that it will not necessarily detect non-positive-definiteness. Indeed the routine may return a factorization that can satisfactorily be used by F04MAF even when A is not positive-definite, but this should not be relied upon as F04MAF may not converge.

9. Example

The example program illustrates the use of F01MAF in conjunction with F04MAF to solve the 16 linear equations $Ax=b$, where

$$A = \begin{pmatrix} 1 & z & & & & \\ z & 1 & z & & & \\ & z & 1 & z & & \\ & & z & 1 & 0 & z \\ z & & & 0 & 1 & z & z \\ & z & & z & 1 & z & z \\ & & z & & z & 1 & z & z \\ & & & z & & z & 1 & 0 & z \\ & & & & z & & 0 & 1 & z & z \\ & & & & & z & & z & 1 & z \end{pmatrix}.$$

$$\begin{pmatrix} & & z & & z & 1 & z \\ & & & z & & & z & 1 \end{pmatrix}$$

$$\begin{matrix} T & (& 1 & 1 & 1 & 1 & 1 & & 1 & 1 & & 1 & 1 & 1 & 1 & 1) \\ b = & (& - & - & - & - & - & 0 & 0 & - & - & 0 & 0 & - & - & - & -) \\ & (& 2 & 4 & 4 & 2 & 4 & & 4 & 4 & & 4 & 2 & 4 & 4 & 2) \end{matrix}$$

where $z = -\frac{1}{4}$.

The n by n matrix A arises in the solution of Laplace's equation in a unit square, using a 5-point formula with a 6 by 6 discretisation, with unity on the boundaries.

The drop tolerance, DROPTL, is taken as 0.1, and the density factor, DENSW, is taken as 0.8. The value IFAIL = 111 is used so that advisory and error messages will be printed, but soft failure would occur if IFAIL were returned as non-zero.

A relative accuracy of about 0.0001 is requested in the solution from F04MAF, with a maximum of 50 iterations.

The example program for F02FJF illustrates the use of F01MAF and F04MAF in solving an eigenvalue problem.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F01 -- Matrix Factorizations

F01MCF

F01MCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F01MCF computes the Cholesky factorization of a real symmetric positive-definite variable-bandwidth matrix.

2. Specification

```

SUBROUTINE F01MCF (N, A, LAL, NROW, AL, D, IFAIL)
INTEGER          N, LAL, NROW(N), IFAIL
DOUBLE PRECISION A(LAL), AL(LAL), D(N)

```

3. Description

This routine determines the unit lower triangular matrix L and the diagonal matrix D in the Cholesky factorization $A=LDL^T$ of a symmetric positive-definite variable-bandwidth matrix A of order n . (Such a matrix is sometimes called a 'sky-line' matrix.)

The matrix A is represented by the elements lying within the envelope of its lower triangular part, that is, between the first non-zero of each row and the diagonal (see Section 9 for an example). The width $NROW(i)$ of the i th row is the number of elements between the first non-zero element and the element on the diagonal, inclusive. Although, of course, any matrix possesses an envelope as defined, this routine is primarily intended for the factorization of symmetric positive-definite matrices with an average bandwidth which is small compared with n (also see Section 8).

The method is based on the property that during Cholesky factorization there is no fill-in outside the envelope.

The determination of L and D is normally the first of two steps in the solution of the system of equations $Ax=b$. The remaining step, viz. the solution of $LDL^T x=b$ may be carried out using F04MCF.

4. References

- [1] Jennings A (1966) A Compact Storage Scheme for the Solution of Symmetric Linear Simultaneous Equations. Comput. J. 9 281--285.
- [2] Wilkinson J H and Reinsch C (1971) Handbook for Automatic Computation II, Linear Algebra. Springer-Verlag.

5. Parameters

1: N -- INTEGER Input
 On entry: n , the order of the matrix A . Constraint: $N \geq 1$.

- 2: A(LAL) -- DOUBLE PRECISION array Input
 On entry: the elements within the envelope of the lower triangle of the positive-definite symmetric matrix A, taken in row by row order. The following code assigns the matrix elements within the envelope to the correct elements of the array:

```

      K = 0
      DO 20 I = 1, N
      DO 10 J = I-NROW(I)+1, I
      K = K + 1
      A(K) = matrix (I,J)
      10    CONTINUE
      20 CONTINUE

```

See also Section 8.

- 3: LAL -- INTEGER Input
 On entry: the smaller of the dimensions of the arrays A and AL as declared in the calling (sub)program from which F01MCF is called. Constraint: LAL \geq NROW(1) + NROW(2) + ... + NROW(n).
- 4: NROW(N) -- INTEGER array Input
 On entry: NROW(i) must contain the width of row i of the matrix A, i.e., the number of elements between the first (leftmost) non-zero element and the element on the diagonal, inclusive. Constraint: $1 \leq \text{NROW}(i) \leq i$, for $i=1,2,\dots,n$.
- 5: AL(LAL) -- DOUBLE PRECISION array Output
 On exit: the elements within the envelope of the lower triangular matrix L, taken in row by row order. The envelope of L is identical to that of the lower triangle of A. The unit diagonal elements of L are stored explicitly. See also Section 8.
- 6: D(N) -- DOUBLE PRECISION array Output
 On exit: the diagonal elements of the the diagonal matrix D. Note that the determinant of A is equal to the product of these diagonal elements. If the value of the determinant is required it should not be determined by forming the product explicitly, because of the possibility of overflow or underflow. The logarithm of the determinant may safely be formed from the sum of the logarithms of the diagonal elements.

7: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

On entry $N < 1$,

or for some i , $NROW(i) < 1$ or $NROW(i) > i$,

or $LAL < NROW(1) + NROW(2) + \dots + NROW(N)$.

IFAIL= 2

A is not positive-definite, or this property has been destroyed by rounding errors. The factorization has not been completed.

IFAIL= 3

A is not positive-definite, or this property has been destroyed by rounding errors. The factorization has been completed but may be very inaccurate (see Section 7).

7. Accuracy

If IFAIL = 0 on exit, then the computed L and D satisfy the relation $LDL^T = A + F$, where

$$\|F\|_2 \leq \kappa_m(A) \max_i a_{ii} \epsilon$$

and

$$\|F\|_2 \leq \kappa_m(A) \|A\|_2 \epsilon$$

where k is a constant of order unity, m is the largest value of $NROW(i)$, and (ϵ) is the machine precision. See Wilkinson and Reinsch [2], pp 25--27, 54--55. If $IFAIL = 3$ on exit, then the factorization has been completed although the matrix was not positive-definite. However the factorization may be very inaccurate and should be used only with great caution. For instance, if it is used to solve a set of equations $Ax=b$ using `F04MCF`, the residual vector $b-Ax$ should be checked.

8. Further Comments

The time taken by the routine is approximately proportional to the sum of squares of the values of $NROW(i)$.

The distribution of row widths may be very non-uniform without undue loss of efficiency. Moreover, the routine has been designed to be as competitive as possible in speed with routines designed for full or uniformly banded matrices, when applied to such matrices.

Unless otherwise stated in the Users' Note for your implementation, the routine may be called with the same actual array supplied for parameters A and AL , in which case L overwrites the lower triangle of A . However this is not standard Fortran 77 and may not work in all implementations.

9. Example

To obtain the Cholesky factorization of the symmetric matrix, whose lower triangle is:

```
(1           )
(2  5        )
(0  3 13     )
(0  0  0 16   )
(5 14 18  8 55 )
(0  0  0 24 17 77)
```

For this matrix, the elements of $NROW$ must be set to 1, 2, 2, 1, 5, 3, and the elements within the envelope must be supplied in row order as:

1, 2, 5, 3, 13, 16, 5, 14, 18, 8, 55, 24, 17, 77.

The example program is not reproduced here. The source code for

all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F01 -- Matrix Factorizations F01QCF
 F01QCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F01QCF finds the QR factorization of the real m by n matrix A , where $m \geq n$.

2. Specification

```
SUBROUTINE F01QCF (M, N, A, LDA, ZETA, IFAIL)
  INTEGER          M, N, LDA, IFAIL
  DOUBLE PRECISION A(LDA,*), ZETA(*)
```

3. Description

The m by n matrix A is factorized as

$$\begin{aligned} & \begin{pmatrix} R \\ 0 \end{pmatrix} \\ A &= Q \begin{pmatrix} R \\ 0 \end{pmatrix} \quad \text{when } m > n, \\ A &= QR \quad \text{when } m = n, \end{aligned}$$

where Q is an m by m orthogonal matrix and R is an n by n upper triangular matrix. The factorization is obtained by Householder's method. The k th transformation matrix, Q_k , which is used to introduce zeros into the k th column of A is given in the form

$$Q_k = \begin{pmatrix} I & 0 \\ 0 & T \end{pmatrix}$$

$k \quad \begin{pmatrix} & & \\ & & k \end{pmatrix}$

where

T

$$T_k = I - u_k u_k^T,$$

$$u_k = \begin{pmatrix} (zeta)_k \\ z_k \end{pmatrix},$$

$(zeta)_k$ is a scalar and z_k is an $(m-k)$ element vector. $(zeta)_k$ and z_k are chosen to annihilate the elements below the triangular part of A .

The vector u_k is returned in the k th element of the array ZETA and in the k th column of A , such that $(zeta)_k$ is in ZETA(k) and the elements of z_k are in $A(k+1,k), \dots, A(m,k)$. The elements of R_k are returned in the upper triangular part of A .

Q is given by

$$Q = \begin{pmatrix} Q_n & Q_{n-1} & \dots & Q_1 \end{pmatrix}^T.$$

Good background descriptions to the QR factorization are given in Dongarra et al [1] and Golub and Van Loan [2], but note that this routine is not based upon LINPACK routine DQRDC.

4. References

- [1] Dongarra J J, Moler C B, Bunch J R and Stewart G W (1979) LINPACK Users' Guide. SIAM, Philadelphia.
- [2] Golub G H and Van Loan C F (1989) Matrix Computations (2nd Edition). Johns Hopkins University Press, Baltimore, Maryland.
- [3] Wilkinson J H (1965) The Algebraic Eigenvalue Problem. Oxford University Press.

5. Parameters

- 1: M -- INTEGER Input
 On entry: m, the number of rows of A. Constraint: $M \geq N$.
- 2: N -- INTEGER Input
 On entry: n, the number of columns of A.
- When $N = 0$ then an immediate return is effected.
 Constraint: $N \geq 0$.
- 3: A(LDA,*) -- DOUBLE PRECISION array Input/Output
 Note: the second dimension of the array A must be at least $\max(1, n)$.
 On entry: the leading m by n part of the array A must contain the matrix to be factorized. On exit: the n by n upper triangular part of A will contain the upper triangular matrix R and the m by n strictly lower triangular part of A will contain details of the factorization as described in Section 3.
- 4: LDA -- INTEGER Input
 On entry:
 the first dimension of the array A as declared in the (sub)program from which F01QCF is called.
 Constraint: $LDA \geq \max(1, M)$.
- 5: ZETA(*) -- DOUBLE PRECISION array Output
 Note: the dimension of the array ZETA must be at least $\max(1, n)$ On exit: ZETA(k) contains the scalar (zeta) for the k
 th transformation. If $T = I$ then $ZETA(k) = 0.0$, otherwise ZETA(k) contains (zeta) as described in Section 3 and (zeta) is
 always in the range $(1.0, \sqrt{2.0})$.
- 6: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry $IFAIL = 0$ or -1 , explanatory error messages are output on the current error message unit (as defined by `X04AAF`).

$IFAIL = -1$

On entry $M < N$,

or $N < 0$,

or $LDA < M$.

7. Accuracy

The computed factors Q and R satisfy the relation

$$\begin{matrix} (R) \\ Q(0) = A + E, \end{matrix}$$

where

$$|||E||| \leq c(\text{epsilon}) |||A|||,$$

and (epsilon) is the machine precision (see `X02AJF(*)`), c is a modest function of m and n and $|||.|||$ denotes the spectral (two) norm.

8. Further Comments

The approximate number of floating-point operations is given by

$$2n^2 (3m - n) / 3.$$

Following the use of this routine the operations

$$B := QB \quad \text{and} \quad B := Q^T B,$$

where B is an m by k matrix, can be performed by calls to `F01QDF`. The operation $B := QB$ can be obtained by the call:

```
IFAIL = 0
CALL F01QDF('No transpose', 'Separate', M, N, A, LDA, ZETA,
*          K, B, LDB, WORK, IFAIL)
```

T
and B:=Q B can be obtained by the call:

```

IFAIL = 0
CALL F01QDF('Transpose', 'Separate', M, N, A, LDA, ZETA,
*          K, B, LDB, WORK, IFAIL)

```

In both cases WORK must be a k element array that is used as workspace. If B is a one-dimensional array (single column) then the parameter LDB can be replaced by M. See F01QDF for further details.

The first k columns of the orthogonal matrix Q can either be obtained by setting B to the first k columns of the unit matrix and using the first of the above two calls, or by calling FO1QEF, which overwrites the k columns of Q on the first k columns of the array A. Q is obtained by the call:

```
CALL F01QEF('Separate', M, N, K, A, LDA, ZETA, WORK, IFAIL)
```

As above WORK must be a k element array. If k is larger than N, then A must have been declared to have at least k columns.

Operations involving the matrix R can readily be performed by the Level 2 BLAS routines DTRSV and DTRMV (see Chapter F06), but note that no test for near singularity of R is incorporated in DTRSV. If R is singular, or nearly singular then F02WUF(*) can be used to determine the singular value decomposition of R.

9. Example

To obtain the QR factorization of the 5 by 3 matrix

$$A = \begin{pmatrix} 2.0 & 2.5 & 2.5 \\ 2.0 & 2.5 & 2.5 \\ 1.6 & -0.4 & 2.8 \\ 2.0 & -0.5 & 0.5 \\ 1.2 & -0.3 & -2.9 \end{pmatrix}$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F01 -- Matrix Factorizations

F01QDF

F01QDF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F01QDF performs one of the transformations

$$B := QB \text{ or } B := Q^T B,$$

where B is an m by ncolb real matrix and Q is an m by m orthogonal matrix, given as the product of Householder transformation matrices.

This routine is intended for use following F01QCF or F01QFF(*).

2. Specification

```

      SUBROUTINE F01QDF (TRANS, WHERE, M, N, A, LDA, ZETA,
1      NCOLB, B, LDB, WORK, IFAIL)
      INTEGER          M, N, LDA, NCOLB, LDB, IFAIL
      DOUBLE PRECISION A(LDA,*), ZETA(*), B(LDB,*), WORK(*)
      CHARACTER*1      TRANS, WHERE

```

3. Description

Q is assumed to be given by

$$Q = \begin{pmatrix} Q_1 & Q_2 & \dots & Q_n \\ Q_{n-1} & & & \end{pmatrix}^T,$$

Q_k being given in the form

$$Q_k = \begin{pmatrix} I & 0 \\ 0 & T \end{pmatrix},$$

k (k)

where

$$T = I - u_k u_k^T,$$

$$u_k = (z_k, (zeta)_k),$$

$(zeta)_k$ is a scalar and z_k is an $(m-k)$ element vector. z_k must be supplied in the k th column of A in elements $A(k+1,k), \dots, A(m,k)$ and $(zeta)_k$ must be supplied either in $A(k,k)$ or in $ZETA(k)$, depending upon the parameter `WHERE`.

To obtain Q explicitly B may be set to I and pre-multiplied by Q^T . This is more efficient than obtaining Q .

4. References

- [1] Golub G H and Van Loan C F (1989) Matrix Computations (2nd Edition). Johns Hopkins University Press, Baltimore, Maryland.
- [2] Wilkinson J H (1965) The Algebraic Eigenvalue Problem. Oxford University Press.

5. Parameters

- 1: `TRANS` -- CHARACTER*1 Input
 On entry: the operation to be performed as follows:
`TRANS = 'N'` (No transpose)
 Perform the operation $B := QB$.

`TRANS = 'T' or 'C'` (Transpose)
 Perform the operation $B := Q^T B$.
 Constraint: `TRANS` must be one of 'N', 'T' or 'C'.
- 2: `WHERE` -- CHARACTER*1 Input
 On entry: indicates where the elements of $(zeta)$ are to be found as follows:
`WHERE = 'I'` (In A)

The elements of (zeta) are in A.

WHERE = 'S' (Separate)

The elements of (zeta) are separate from A, in ZETA.
Constraint: WHERE must be one of 'I' or 'S'.

3: M -- INTEGER Input
On entry: m, the number of rows of A. Constraint: M >= N.

4: N -- INTEGER Input
On entry: n, the number of columns of A.

When N = 0 then an immediate return is effected.
Constraint: N >= 0.

5: A(LDA,*) -- DOUBLE PRECISION array Input
Note: the second dimension of the array A must be at least max(1,N).
On entry: the leading m by n strictly lower triangular part of the array A must contain details of the matrix Q. In addition, when WHERE = 'I', then the diagonal elements of A must contain the elements of (zeta) as described under the argument ZETA below.

When WHERE = 'S', the diagonal elements of the array A are referenced, since they are used temporarily to store the (zeta)_k, but they contain their original values on return.

6: LDA -- INTEGER Input
On entry:
the first dimension of the array A as declared in the (sub)program from which F01QDF is called.
Constraint: LDA >= max(1,M).

7: ZETA(*) -- DOUBLE PRECISION array Input
Note: when WHERE = 'S', the dimension of the array ZETA must be greater than or equal to max(1,N). On entry: if WHERE = 'S', the array ZETA must contain the elements of (zeta). If ZETA(k) = 0.0 then T_k is assumed to be I otherwise ZETA(k) is assumed to contain (zeta)_k.

When WHERE = 'I', ZETA is not referenced.

8: NCOLB -- INTEGER Input
 On entry: ncolb, number of columns of B.

When NCOLB = 0 then an immediate return is effected.
 Constraint: NCOLB \geq 0.

9: B(LDB,*) -- DOUBLE PRECISION array Input/Output
 Note: the second dimension of the array B must be at least max(1,NCOLB).
 On entry: the leading m by ncolb part of the array B must contain the matrix to be transformed. On exit: B is overwritten by the transformed matrix.

10: LDB -- INTEGER Input
 On entry:
 the first dimension of the array B as declared in the (sub)program from which F01QDF is called.
 Constraint: LDB \geq max(1,M).

11: WORK(*) -- DOUBLE PRECISION array Workspace
 Note: the dimension of the array WORK must be at least max(1,NCOLB).

12: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL=-1

On entry TRANS \neq 'N', 'T' or 'C',

or WHERET \neq 'I' or 'S',

or M < N,

or N < 0,

or $LDA < M$,

or $NCOLB < 0$,

or $LDB < M$.

7. Accuracy

Letting C denote the computed matrix $Q^T B$, C satisfies the relation

$$QC = B + E,$$

where

$$\|E\| \leq c(\text{epsilon}) \|B\|,$$

and (epsilon) the machine precision (see X02AJF(*)), c is a modest function of m and $\| \cdot \|$ denotes the spectral (two) norm. An equivalent result holds for the computed matrix QB . See also Section 7 of F01QCF.

8. Further Comments

The approximate number of floating-point operations is given by $2n(2m-n)\text{ncolb}$.

9. Example

To obtain the matrix $Q^T B$ for the matrix B given by

$$B = \begin{pmatrix} 1.1 & 0.00 \\ 0.9 & 0.00 \\ 0.6 & 1.32 \\ 0.0 & 1.10 \\ -0.8 & -0.26 \end{pmatrix}$$

following the QR factorization of the 5 by 3 matrix A given by

$$A = \begin{pmatrix} 2.0 & 2.5 & 2.5 \\ 2.0 & 2.5 & 2.5 \\ 1.6 & -0.4 & 2.8 \\ 2.0 & -0.5 & 0.5 \end{pmatrix}.$$

(1.2 -0.3 -2.9)

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F01 -- Matrix Factorizations F01QEF
 F01QEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F01QEF returns the first ncolq columns of the real m by m orthogonal matrix Q, where Q is given as the product of Householder transformation matrices.

This routine is intended for use following F01QCF or F01QFF(*).

2. Specification

```

      SUBROUTINE F01QEF (WHERE, M, N, NCOLQ, A, LDA, ZETA,
1      WORK, IFAIL)
      INTEGER          M, N, NCOLQ, LDA, IFAIL
      DOUBLE PRECISION A(LDA,*), ZETA(*), WORK(*)
      CHARACTER*1      WHERE
  
```

3. Description

Q is assumed to be given by

$$Q = \begin{pmatrix} Q_1 & Q_2 & \dots & Q_n \\ & & & \end{pmatrix}^T$$

n n-1 1

Q_k being given in the form

$$Q_k = \begin{pmatrix} I & 0 \\ 0 & T \end{pmatrix}$$

k k

where

$$T_k = I - u_k u_k^T,$$

$$u_k = \frac{((zeta)_k)}{\|z_k\|},$$

$(zeta)_k$ is a scalar and z_k is an $(m-k)$ element vector. z_k must be supplied in the k th column of A in elements $A(k+1,k), \dots, A(m,k)$ and $(zeta)_k$ must be supplied either in $A(k,k)$ or in $ZETA(k)$, depending upon the parameter `WHERE`.

4. References

- [1] Golub G H and Van Loan C F (1989) Matrix Computations (2nd Edition). Johns Hopkins University Press, Baltimore, Maryland.
- [2] Wilkinson J H (1965) The Algebraic Eigenvalue Problem. Oxford University Press.

5. Parameters

- 1: `WHERE` -- CHARACTER*1 Input
 On entry: indicates where the elements of $(zeta)$ are to be found as follows:
`WHERE = 'I'` (In A)
 The elements of $(zeta)$ are in A .

`WHERE = 'S'` (Separate)
 The elements of $(zeta)$ are separate from A , in $ZETA$.
 Constraint: `WHERE` must be one of 'I' or 'S'.
- 2: `M` -- INTEGER Input
 On entry: m , the number of rows of A . Constraint: $M \geq N$.
- 3: `N` -- INTEGER Input
 On entry: n , the number of columns of A . Constraint: $N \geq 0$.

- 4: NCOLQ -- INTEGER Input
 On entry: ncolq, the required number of columns of Q.
 Constraint: $0 \leq \text{NCOLQ} \leq M$.

When NCOLQ = 0 then an immediate return is effected.

- 5: A(LDA,*) -- DOUBLE PRECISION array Input/Output
 Note: the second dimension of the array A must be at least $\max(1, N, \text{NCOLQ})$.
 On entry: the leading m by n strictly lower triangular part of the array A must contain details of the matrix Q. In addition, when WHERE = 'I', then the diagonal elements of A must contain the elements of (zeta) as described under the argument ZETA below. On exit: the first NCOLQ columns of the array A are overwritten by the first NCOLQ columns of the m by m orthogonal matrix Q. When N = 0 then the first NCOLQ columns of A are overwritten by the first NCOLQ columns of the identity matrix.

- 6: LDA -- INTEGER Input
 On entry:
 the first dimension of the array A as declared in the (sub)program from which F01QEF is called.
 Constraint: $\text{LDA} \geq \max(1, M)$.

- 7: ZETA(*) -- DOUBLE PRECISION array Input
 Note: the dimension of the array ZETA must be at least $\max(1, N)$.
 On entry: with WHERE = 'S', the array ZETA must contain the elements of (zeta). If $\text{ZETA}(k) = 0.0$ then T_k is assumed to be I, otherwise $\text{ZETA}(k)$ is assumed to contain (zeta)_k.

When WHERE = 'I', the array ZETA is not referenced.

- 8: WORK(*) -- DOUBLE PRECISION array Workspace
 Note: the dimension of the array WORK must be at least $\max(1, \text{NCOLQ})$.

- 9: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL=-1

On entry WHEREI /= 'I' or 'S',

or $M < N$,

or $N < 0$,

or $NCOLQ < 0$ or $NCOLQ > M$,

or $LDA < M$.

7. Accuracy

The computed matrix Q satisfies the relation

$$Q = P + E,$$

where P is an exactly orthogonal matrix and

$$\|E\| \leq c(\text{epsilon})$$

(epsilon) is the machine precision (see X02AJF(*)), c is a modest function of m and $\| \cdot \|$ denotes the spectral (two) norm. See also Section 7 of F01QCF.

8. Further Comments

The approximate number of floating-point operations required is given by

$$\frac{2}{3} n \{ (3m-n)(2ncolq-n) - n(ncolq-n) \}, \quad ncolq > n,$$

$$\frac{2}{3} ncolq^2 (3m - ncolq), \quad ncolq \leq n.$$

3

9. Example

To obtain the 5 by 5 orthogonal matrix Q following the QR factorization of the 5 by 3 matrix A given by

```

      (2.0  2.5  2.5)
      (2.0  2.5  2.5)
A=(1.6 -0.4  2.8).
      (2.0 -0.5  0.5)
      (1.2 -0.3 -2.9)

```

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

F01 -- Matrix Factorizations                                F01RCF
      F01RCF -- NAG Foundation Library Routine Document

```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F01RCF finds the QR factorization of the complex m by n matrix A, where $m \geq n$.

2. Specification

```

      SUBROUTINE  F01RCF (M, N, A, LDA, THETA, IFAIL)
      INTEGER     M, N, LDA, IFAIL
      COMPLEX(KIND(1.0D0)) A(LDA,*), THETA(*)

```

3. Description

The m by n matrix A is factorized as

```

      (R)
A=Q(O)      when m>n,

A=QR       when m=n,

```

where Q is an m by m unitary matrix and R is an n by n upper triangular matrix with real diagonal elements.

The factorization is obtained by Householder's method. The k th transformation matrix, Q_k , which is used to introduce zeros into the k th column of A is given in the form

$$Q_k = \begin{pmatrix} I & 0 \\ 0 & T_k \end{pmatrix},$$

where

$$T_k = I - (\gamma_k) u_k u_k^H,$$

$$u_k = \begin{pmatrix} (\zeta_k) \\ (z_k) \end{pmatrix},$$

(γ_k) is a scalar for which $\text{Re}(\gamma_k) = 1.0$, (ζ_k) is a real scalar and z_k is an $(m-k)$ element vector. (γ_k) , (ζ_k) and z_k are chosen to annihilate the elements below the triangular part of A and to make the diagonal elements real.

The scalar (γ_k) and the vector u_k are returned in the k th element of the array THETA and in the k th column of A , such that (θ_k) , given by

$$(\theta_k) = ((\zeta_k), \text{Im}(\gamma_k)),$$

is in THETA(k) and the elements of z_k are in $a_{k+1,k}, \dots, a_{m,k}$. The elements of R are returned in the upper triangular part of A .

Q is given by

$$Q = \begin{pmatrix} Q_1 & Q_2 & \dots & Q_n \\ & & & \end{pmatrix} \begin{matrix} H \\ \\ \\ \end{matrix}$$

A good background description to the QR factorization is given in Dongarra et al [1], but note that this routine is not based upon LINPACK routine ZQRDC.

4. References

- [1] Dongarra J J, Moler C B, Bunch J R and Stewart G W (1979) LINPACK Users' Guide. SIAM, Philadelphia.
- [2] Wilkinson J H (1965) The Algebraic Eigenvalue Problem. Oxford University Press.

5. Parameters

- 1: M -- INTEGER Input
On entry: m, the number of rows of A. Constraint: M >= N.
- 2: N -- INTEGER Input
On entry: n, the number of columns of A. Constraint: N >= 0.

When N = 0 then an immediate return is effected.

- 3: A(LDA,*) -- COMPLEX(KIND(1.0D0)) array Input/Output
Note: the second dimension of the array A must be at least max(1,N).
On entry: the leading m by n part of the array A must contain the matrix to be factorized. On exit: the n by n upper triangular part of A will contain the upper triangular matrix R, with the imaginary parts of the diagonal elements set to zero, and the m by n strictly lower triangular part of A will contain details of the factorization as described above.
- 4: LDA -- INTEGER Input
On entry:
the first dimension of the array A as declared in the (sub)program from which F01RCF is called.
Constraint: LDA >= max(1,M).
- 5: THETA(*) -- COMPLEX(KIND(1.0D0)) array Output

Note: the dimension of the array THETA must be at least $\max(1, N)$.
 On exit: the scalar $(\theta)_k$ for the k th transformation. If
 $T = I$ then $\text{THETA}(k) = 0.0$; if

$$T = \begin{pmatrix} (\alpha)_k & 0 \\ 0 & 1 \end{pmatrix} \quad \text{Re}(\alpha)_k < 0.0,$$

 then $\text{THETA}(k) = (\alpha)_k$; otherwise $\text{THETA}(k)$ contains $\text{THETA}(k)$
 as described in Section 3 and $\text{Re}(\text{THETA}(k))$ is always in the
 range $(1.0, \sqrt{2.0})$.

6: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not
 familiar with this parameter (described in the Essential
 Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see
 Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
 output on the current error message unit (as defined by X04AAF).

IFAIL=-1

On entry $M < N$,
 or $N < 0$,
 or $LDA < M$.

7. Accuracy

The computed factors Q and R satisfy the relation

$$\begin{matrix} (R) \\ Q(0) = A + E, \end{matrix}$$

where

$$\|E\| \leq c(\epsilon) \|A\|,$$

(epsilon) being the machine precision, c is a modest function of m and n and $||.||$ denotes the spectral (two) norm.

8. Further Comments

The approximate number of real floating-point operations is given by $8n(3m-n)/3$.

Following the use of this routine the operations

$$B := QB \quad \text{and} \quad B := Q^H B,$$

where B is an m by k matrix, can be performed by calls to F01RDF. The operation $B := QB$ can be obtained by the call:

```
IFAIL = 0
CALL F01RDF('No conjugate', 'Separate', M, N, A, LDA, THETA,
*          K, B, LDB, WORK, IFAIL)
```

and $B := Q^H B$ can be obtained by the call:

```
IFAIL = 0
CALL F01RDF('Conjugate', 'Separate', M, N, A, LDA, THETA,
*          K, B, LDB, WORK, IFAIL)
```

In both cases WORK must be a k element array that is used as workspace. If B is a one-dimensional array (single column) then the parameter LDB can be replaced by M. See F01RDF for further details.

The first k columns of the unitary matrix Q can either be obtained by setting B to the first k columns of the unit matrix and using the first of the above two calls, or by calling F01REF, which overwrites the k columns of Q on the first k columns of the array A . Q is obtained by the call:

```
CALL F01REF('Separate', M, N, K, A, LDA, THETA, WORK, IFAIL)
```

As above, WORK must be a k element array. If k is larger than n ,

then A must have been declared to have at least k columns.

Operations involving the matrix R can readily be performed by the Level 2 BLAS routines ZTRSV and ZTRMV (see Chapter F06), but note that no test for near singularity of R is incorporated in ZTRSV. If R is singular, or nearly singular, then F02XUF(*) can be used to determine the singular value decomposition of R.

9. Example

To obtain the QR factorization of the 5 by 3 matrix

$$A = \begin{pmatrix} 0.5i & -0.5+1.5i & -1.0+1.0i \\ 0.4+0.3i & 0.9+1.3i & 0.2+1.4i \\ 0.4 & -0.4+0.4i & 1.8 \\ 0.3-0.4i & 0.1+0.7i & 0.0 \\ -0.3i & 0.3+0.3i & 2.4i \end{pmatrix}.$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%

F01 -- Matrix Factorizations

F01RDF

F01RDF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F01RDF performs one of the transformations

$$B := QB \text{ or } B := Q^H B,$$

where B is an m by ncolb complex matrix and Q is an m by m unitary matrix, given as the product of Householder transformation matrices.

This routine is intended for use following F01RCF or F01RFF(*).

2. Specification

```

SUBROUTINE F01RDF (TRANS, WHERE, M, N, A, LDA, THETA,
1                NCOLB, B, LDB, WORK, IFAIL)
INTEGER          M, N, LDA, NCOLB, LDB, IFAIL
COMPLEX(KIND(1.0D0)) A(LDA,*), THETA(*), B(LDB,*), WORK(*)
CHARACTER*1      TRANS, WHERE

```

3. Description

The unitary matrix Q is assumed to be given by

$$Q = \begin{pmatrix} Q_{11} & \dots & Q_{1n} \\ \vdots & \ddots & \vdots \\ Q_{n1} & \dots & Q_{nn} \end{pmatrix}^H,$$

Q being given in the form

$$Q_k = \begin{pmatrix} I & 0 \\ 0 & T_k \end{pmatrix},$$

where

$$T_k = I - (\gamma_k) u_k u_k^H,$$

$$u_k = \begin{pmatrix} (\zeta_k) \\ (z_k) \end{pmatrix},$$

(γ_k) is a scalar for which $\text{Re}(\gamma_k) = 1.0$, (ζ_k) is a real scalar and z_k is an $(m-k)$ element vector.

z_k must be supplied in the k th column of A in elements $a_{k+1,k}, \dots, a_{m,k}$ and (θ_k) , given by

$$(\theta_k) = ((\zeta_k), \text{Im}(\gamma_k)),$$

must be supplied either in $a_{k,k}$ or in $\text{THETA}(k)$, depending upon the parameter `WHERE`.

To obtain Q explicitly B may be set to I and pre-multiplied by Q .

$$Q = Q^H$$
This is more efficient than obtaining Q^H . Alternatively, `F01REF` may be used to obtain Q overwritten on A .

4. References

- [1] Wilkinson J H (1965) The Algebraic Eigenvalue Problem.
 Oxford University Press.

5. Parameters

- 1: `TRANS` -- CHARACTER*1 Input
 On entry: the operation to be performed as follows:
`TRANS = 'N'` (No transpose)
 Perform the operation $B := QB$.

`TRANS = 'C'` (Conjugate transpose)

$$B = Q^H B$$
 Perform the operation $B := Q^H B$.
 Constraint: `TRANS` must be one of 'N' or 'C'.

- 2: `WHERE` -- CHARACTER*1 Input
 On entry: the elements of (θ) are to be found as follows:
`WHERE = 'I'` (In A)
 The elements of (θ) are in A .

`WHERE = 'S'` (Separate)
 The elements of (θ) are separate from A , in THETA .
 Constraint: `WHERE` must be one of 'I' or 'S'.

- 3: `M` -- INTEGER Input
 On entry: m , the number of rows of A . Constraint: $M \geq N$.

- 4: `N` -- INTEGER Input
 On entry: n , the number of columns of A . Constraint: $N \geq 0$.

 When $N = 0$ then an immediate return is effected.

- 5: `A(LDA,*)` -- COMPLEX(KIND(1.0D0)) array Input

Note: the second dimension of the array A must be at least $\max(1, N)$.

On entry: the leading m by n strictly lower triangular part of the array A must contain details of the matrix Q. In addition, when WHERET = 'I', then the diagonal elements of A must contain the elements of (θ) as described under the argument THETA below.

When WHERET = 'S', then the diagonal elements of the array A are referenced, since they are used temporarily to store the (ζ) , but they contain their original values on return.

6: LDA -- INTEGER Input

On entry:

the first dimension of the array A as declared in the (sub)program from which F01RDF is called.

Constraint: $LDA \geq \max(1, M)$.

7: THETA(*) -- COMPLEX(KIND(1.0D)) array Input

Note: the dimension of the array THETA must be at least $\max(1, N)$.

On entry: with WHERET = 'S', the array THETA must contain the elements of (θ) . If $THETA(k)=0.0$ then T is assumed

to be I; if $THETA(k)=(\alpha)$, with $\text{Re}(\alpha) < 0.0$, then T is assumed to be of the form

$$T = \begin{pmatrix} (\alpha) & 0 \\ 0 & I \end{pmatrix};$$

otherwise $THETA(k)$ is assumed to contain (θ) given by

$$(\theta) = \begin{pmatrix} (\zeta) & \text{Im}(\gamma) \end{pmatrix}.$$

When WHERET = 'I', the array THETA is not referenced, and may be dimensioned of length 1.

8: NCOLB -- INTEGER Input

On entry: ncolb, the number of columns of B. Constraint: $NCOLB \geq 0$.

When $NCOLB = 0$ then an immediate return is effected.

9: B(LDB,*) -- COMPLEX(KIND(1.0D)) array Input/Output

Note: the second dimension of the array B must be at least

`max(1,NCOLB).`

On entry: the leading `m` by `ncolb` part of the array `B` must contain the matrix to be transformed. On exit: `B` is overwritten by the transformed matrix.

- 10: `LDB` -- INTEGER Input
 On entry:
 the first dimension of the array `B` as declared in the (sub)program from which `F01RDF` is called.
 Constraint: `LDB` \geq `max(1,M)`.
- 11: `WORK(*)` -- `COMPLEX(KIND(1.0D))` array Workspace
 Note: the dimension of the array `WORK` must be at least `max(1,NCOLB)`.
- 12: `IFAIL` -- INTEGER Input/Output
 On entry: `IFAIL` must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

 On exit: `IFAIL` = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry `IFAIL` = 0 or -1, explanatory error messages are output on the current error message unit (as defined by `X04AAF`).

`IFAIL=-1`

On entry `TRANS` \neq 'N' or 'C',

 or `WHERE` \neq 'I' or 'S',

 or `M` < `N`,

 or `N` < 0,

 or `LDA` < `M`,

 or `NCOLB` < 0,

 or `LDB` < `M`.

7. Accuracy

Letting C denote the computed matrix $Q B$, C satisfies the relation

$$QC=B+E,$$

where

$$||E|| \leq c(\text{epsilon}) ||B||,$$

(epsilon) being the machine precision, c is a modest function of m and $|||.|||$ denotes the spectral (two) norm. An equivalent result holds for the computed matrix QB . See also Section 7 of F01RCF.

8. Further Comments

The approximate number of real floating-point operations is given by $8n(2m-n)\text{ncolb}$.

9. Example

H

To obtain the matrix $Q B$ for the matrix B given by

$$B = \begin{pmatrix} -0.55+1.05i & 0.45+1.05i \\ 0.49+0.93i & 1.09+0.13i \\ 0.56-0.16i & 0.64+0.16i \\ 0.39+0.23i & -0.39-0.23i \\ 1.13+0.83i & -1.13+0.77i \end{pmatrix}$$

following the QR factorization of the 5 by 3 matrix A given by

$$A = \begin{pmatrix} 0.5i & -0.5+1.5i & -1.0+1.0i \\ 0.4+0.3i & 0.9+1.3i & 0.2+1.4i \\ 0.4 & -0.4+0.4i & 1.8 \\ 0.3-0.4i & 0.1+0.7i & 0.0 \\ -0.3i & 0.3+0.3i & 2.4i \end{pmatrix}.$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%

F01REF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

F01REF returns the first $ncolq$ columns of the complex m by m unitary matrix Q , where Q is given as the product of Householder transformation matrices.

This routine is intended for use following F01RCF.

2. Specification

```

      SUBROUTINE F01REF (WHERE, M, N, NCOLQ, A, LDA, THETA,
1      WORK, IFAIL)
      INTEGER          M, N, NCOLQ, LDA, IFAIL
      COMPLEX(KIND(1.0D0)) A(LDA,*), THETA(*), WORK(*)
      CHARACTER*1      WHERE

```

3. Description

The unitary matrix Q is assumed to be given by

$$Q = \begin{pmatrix} Q_{11} & Q_{12} & \dots & Q_{1n} \\ Q_{21} & Q_{22} & \dots & Q_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ Q_{n1} & Q_{n2} & \dots & Q_{nn} \end{pmatrix},$$

Q being given in the form

$$Q = \begin{pmatrix} I & O \\ O & T \end{pmatrix},$$

where

$$T = I - (\gamma)_{kk} u u^H,$$

$$((\gamma)_{kk}) =$$

$$u = (z_k, \dots, z_m)^T,$$

(γ_k) is a scalar for which $\text{Re}(\gamma_k) = 1.0$, (ζ_k) is a real

scalar and z_k is an $(m-k)$ element vector.

z_k must be supplied in the k th column of A in elements $a_{k+1,k}, \dots, a_{m,k}$ and (θ_k) , given by

$$(\theta_k) = ((\zeta_k), \text{Im}(\gamma_k)),$$

must be supplied either in $a_{k,k}$ or in $\text{THETA}(k)$ depending upon the parameter WHERE .

4. References

- [1] Wilkinson J H (1965) The Algebraic Eigenvalue Problem. Oxford University Press.

5. Parameters

- 1: WHERE -- CHARACTER*1 Input
 On entry: the elements of (θ) are to be found as follows:
 $\text{WHERE} = 'I'$ (In A)
 The elements of (θ) are in A .
 $\text{WHERE} = 'S'$ (Separate)
 The elements of (θ) are separate from A , in THETA .
 Constraint: WHERE must be one of 'I' or 'S'.
- 2: M -- INTEGER Input
 On entry: m , the number of rows of A . Constraint: $M \geq N$.
- 3: N -- INTEGER Input
 On entry: n , the number of columns of A . Constraint: $N \geq 0$.
- 4: NCOLQ -- INTEGER Input

On entry: ncolq, the required number of columns of Q.
 Constraint: $0 \leq \text{NCOLQ} \leq M$.

When $\text{NCOLQ} = 0$ then an immediate return is effected.

- 5: A(LDA,*) -- COMPLEX(KIND(1.0D)) array Input/Output
 Note: the second dimension of the array A must be at least $\max(1, N, \text{NCOLQ})$.

On entry: the leading m by n strictly lower triangular part of the array A must contain details of the matrix Q. In addition, when $\text{WHERE} = 'I'$, then the diagonal elements of A must contain the elements of (theta) as described under the argument THETA below. On exit: the first NCOLQ columns of the array A are overwritten by the first NCOLQ columns of the m by m unitary matrix Q. When $N = 0$ then the first NCOLQ columns of A are overwritten by the first NCOLQ columns of the unit matrix.

- 6: LDA -- INTEGER Input

On entry:
 the first dimension of the array A as declared in the (sub)program from which F01REF is called.
 Constraint: $\text{LDA} \geq \max(1, M)$.

- 7: THETA(*) -- COMPLEX(KIND(1.0D)) array Input

Note: the dimension of the array THETA must be at least $\max(1, N)$.

On entry: if $\text{WHERE} = 'S'$, the array THETA must contain the elements of (theta). If $\text{THETA}(k) = 0.0$ then T_k is assumed to

be I ; if $\text{THETA}(k) = (\alpha)$, with $\text{Re}(\alpha) < 0.0$, then T_k is assumed to be of the form

$$T_k = \begin{pmatrix} (\alpha) & 0 \\ 0 & I \end{pmatrix};$$

otherwise $\text{THETA}(k)$ is assumed to contain (theta) given by

$$\begin{pmatrix} \text{theta} \end{pmatrix}_k = \begin{pmatrix} \text{zeta} \end{pmatrix}_k, \text{Im}(\begin{pmatrix} \text{gamma} \end{pmatrix}_k).$$

When $\text{WHERE} = 'I'$, the array THETA is not referenced.

- 8: WORK(*) -- COMPLEX(KIND(1.0D)) array Workspace

Note: the dimension of the array WORK must be at least $\max(1, \text{NCOLQ})$.

9: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL=-1

On entry WHEREI /= 'I' or 'S',
 or $M < N$,
 or $N < 0$,
 or $NCOLQ < 0$ or $NCOLQ > M$,
 or $LDA < M$.

7. Accuracy

The computed matrix Q satisfies the relation

$$Q = P + E,$$

where P is an exactly unitary matrix and

$$\|E\| \leq c(\text{epsilon}),$$

(epsilon) being the machine precision, c is a modest function of m and $\| \cdot \|$ denotes the spectral (two) norm. See also Section 7 of F01RCF.

8. Further Comments

The approximate number of real floating-point operations required is given by

```

8
-n{(3m-n)(2ncolq-n)-n(ncolq-n)},  ncolq>n
3

8      2
-ncolq (3m-ncolq),                ncolq<=n
3

```

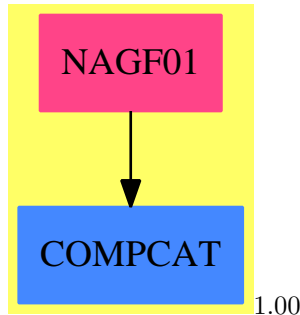

9. Example

To obtain the 5 by 5 unitary matrix Q following the QR factorization of the 5 by 3 matrix A given by

$$\begin{aligned}
 & \begin{pmatrix} 0.5i & -0.5+1.5i & -1.0+1.4i \\ 0.4+0.3i & 0.9+1.3i & 0.2+1.4i \end{pmatrix} \\
 A = & \begin{pmatrix} 0.4 & -0.4+0.4i & 1.8 & & \\ 0.3-0.4i & 0.1+0.7i & 0.0 & & \\ & -0.3i & 0.3+0.3i & & 2.4i \end{pmatrix}.
 \end{aligned}$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

1. Scope of the Chapter

An optimization problem involves minimizing a function (called the objective function) of several variables, possibly subject to restrictions on the values of the variables defined by a set of constraint functions. The routines in the NAG Foundation Library

are concerned with function minimization only, since the problem of maximizing a given function can be transformed into a minimization problem simply by multiplying the function by -1 .

This introduction is only a brief guide to the subject of optimization designed for the casual user. Anyone with a difficult or protracted problem to solve will find it beneficial to consult a more detailed text, such as Gill et al [5] or Fletcher [3].

Readers who are unfamiliar with the mathematics of the subject may find some sections difficult at first reading; if so, they should concentrate on Sections 2.1, 2.2, 2.5, 2.6 and 3.

2. Background to the Problems

2.1. Types of Optimization Problems

Solution of optimization problems by a single, all-purpose, method is cumbersome and inefficient. Optimization problems are therefore classified into particular categories, where each category is defined by the properties of the objective and constraint functions, as illustrated by some examples below.

Properties of Objective Function	Properties of Constraints
Nonlinear	Nonlinear
Sums of squares of nonlinear functions	Sparse linear
Quadratic	Linear
Sums of squares of linear functions	Bounds
Linear	None

For instance, a specific problem category involves the minimization of a nonlinear objective function subject to bounds on the variables. In the following sections we define the particular categories of problems that can be solved by routines contained in this Chapter.

2.1.1. Unconstrained minimization

In unconstrained minimization problems there are no constraints on the variables. The problem can be stated mathematically as follows:

$$\begin{array}{l} \text{minimize } F(x) \\ x \end{array}$$

where x is in R^n , that is, $x = (x_1, x_2, \dots, x_n)^T$.

2.1.2. Nonlinear least-squares problems

Special consideration is given to the problem for which the function to be minimized can be expressed as a sum of squared functions. The least-squares problem can be stated mathematically as follows:

$$\begin{array}{l} \text{minimize } \{ f_i(x) \}_{i=1}^m, \quad x \text{ is in } R^n \\ x \end{array}$$

where the i th element of the m -vector f is the function $f_i(x)$.

2.1.3. Minimization subject to bounds on the variables

These problems differ from the unconstrained problem in that at least one of the variables is subject to a simple restriction on its value, e.g. $x_i \leq 10$, but no constraints of a more general form are present.

The problem can be stated mathematically as follows:

$$\begin{array}{l} \text{minimize } F(x), \quad x \text{ is in } R^n \\ x \end{array}$$

subject to $l_i \leq x_i \leq u_i, \quad i=1,2,\dots,n.$

This format assumes that upper and lower bounds exist on all the

variables. By conceptually allowing $u_i = \infty$ and $l_i = -\infty$ all the variables need not be restricted.

2.1.4. Minimization subject to linear constraints

A general linear constraint is defined as a constraint function that is linear in more than one of the variables, e.g. $3x_1 + 2x_2 \geq 4$

The various types of linear constraint are reflected in the following mathematical statement of the problem:

$$\begin{array}{l} \text{minimize } F(x), \quad x \text{ is in } R^n \\ x \end{array}$$

subject to the

$$\begin{array}{ll} \text{equality} & \begin{array}{l} T \\ a_i x_i = b_i \quad i=1,2,\dots,m; \\ \text{constraints:} \end{array} \\ \text{inequality} & \begin{array}{l} T \\ a_i x_i \geq b_i \quad i=m+1, m+2, \dots, m; \\ \text{constraints:} \end{array} \\ & \begin{array}{l} T \\ a_i x_i \leq b_i \quad i=m+1, m+2, \dots, m; \\ \text{constraints:} \end{array} \\ \text{range} & \begin{array}{l} T \\ s_j \leq a_j x_j \leq t_j \quad j=m+1, m+2, \dots, m; \\ \text{constraints:} \end{array} \\ & \begin{array}{l} T \\ s_j \leq a_j x_j \leq t_j \quad j=1,2,\dots, m-m; \\ \text{constraints:} \end{array} \\ \text{bounds} & \begin{array}{l} l_i \leq x_i \leq u_i \quad i=1,2,\dots,n \\ \text{constraints:} \end{array} \end{array}$$

where each a_i is a vector of length n ; b_i , s_j and t_j are constant scalars; and any of the categories may be empty.

Although the bounds on x_i could be included in the definition of

general linear constraints, we prefer to distinguish between them for reasons of computational efficiency.

If $F(x)$ is a linear function, the linearly-constrained problem is termed a linear programming problem (LP problem); if $F(x)$ is a quadratic function, the problem is termed a quadratic programming problem (QP problem). For further discussion of LP and QP problems, including the dual formulation of such problems, see Dantzig [2].

2.1.5. Minimization subject to nonlinear constraints

A problem is included in this category if at least one constraint

function is nonlinear, e.g. $x_1^2 + x_3 + x_4 - 2 \geq 0$. The mathematical

statement of the problem is identical to that for the linearly-constrained case, except for the addition of the following constraints:

equality	$c_i(x) = 0$	$i = 1, 2, \dots, m$;
constraints:	i	5
inequality	$c_i(x) \geq 0$	$i = m+1, m+2, \dots, m$;
constraints:	i	5 5 6
range	$v_j \leq c_j(x) \leq w_j$	$j = m+1, m+2, \dots, m$,
constraints:	j	6 6 7
		$j = 1, 2, \dots, m-m$
		7 6

where each c_i is a nonlinear function; v_j and w_j are constant scalars; and any category may be empty. Note that we do not include a separate category for constraints of the form $c_i(x) \leq 0$,

since this is equivalent to $-c_i(x) \geq 0$.

2.2. Geometric Representation and Terminology

To illustrate the nature of optimization problems it is useful to consider the following example in two dimensions

x
1 2 2

$$F(x) = e^{(4x_1 + 2x_2 + 4x_1x_2 + 2x_2^2 + 1)}.$$

(This function is used as the example function in the documentation for the unconstrained routines.)

Figure 1
Please see figure in printed Reference Manual

Figure 1 is a contour diagram of $F(x)$. The contours labelled F_0, F_1, \dots, F_4 are isovalue contours, or lines along which the

function $F(x)$ takes specific constant values. The point x^* is a local unconstrained minimum, that is, the value of $F(x^*)$ is less than at all the neighbouring points. A function may have several such minima. The lowest of the local minima is termed a global minimum. In the problem illustrated in Figure 1, x^* is the only

local minimum. The point x is said to be a saddle point because it is a minimum along the line AB, but a maximum along CD.

If we add the constraint $x_1 \geq 0$ to the problem of minimizing $F(x)$, the solution remains unaltered. In Figure 1 this constraint is represented by the straight line passing through $x_1 = 0$, and the shading on the line indicates the unacceptable region. The region in R^n satisfying the constraints of an optimization problem is termed the feasible region. A point satisfying the constraints is defined as a feasible point.

If we add the nonlinear constraint $x_1 + x_2 - x_1x_2 - 1.5 \geq 0$, represented by the curved shaded line in Figure 1, then x^* is not a feasible point. The solution of the new constrained problem is \hat{x} , the feasible point with the smallest function value.

2.2.1. Gradient vector

The vector of first partial derivatives of $F(x)$ is called the gradient vector, and is denoted by $g(x)$, i.e.,

$$g(x) = \begin{bmatrix} \frac{dF(x)}{dx_1}, \frac{dF(x)}{dx_2}, \dots, \frac{dF(x)}{dx_n} \end{bmatrix}^T.$$

For the function illustrated in Figure 1,

$$F(x) = e^{(8x_1 + 4x_2 + 2)}.$$

$$g(x) = \begin{bmatrix} 8e^{(8x_1 + 4x_2 + 2)} \\ 4e^{(8x_1 + 4x_2 + 2)} \end{bmatrix}.$$

The gradient vector is of importance in optimization because it must be zero at an unconstrained minimum of any function with continuous first derivatives.

2.2.2. Hessian matrix

The matrix of second partial derivatives of a function is termed its Hessian matrix. The Hessian matrix of $F(x)$ is denoted by $G(x)$

and its (i,j) th element is given by $\frac{d^2 F(x)}{dx_i dx_j}$. If $F(x)$ has continuous second derivatives, then $G(x)$ must be positive semi-definite at any unconstrained minimum of F .

2.2.3. Jacobian matrix; matrix of constraint normals

In nonlinear least-squares problems, the matrix of first partial derivatives of the vector-valued function $f(x)$ is termed the Jacobian matrix of $f(x)$ and its (i,j) th component is $\frac{df_i}{dx_j}$.

The vector of first partial derivatives of the constraint $c(x)$ is denoted by

$$\begin{bmatrix} \frac{dc(x)}{dx_1} & \frac{dc(x)}{dx_2} \end{bmatrix}^T$$

$$a_i(x) = \begin{bmatrix} \frac{\partial c_i}{\partial x_1} & \dots & \frac{\partial c_i}{\partial x_n} \end{bmatrix}$$

At a point, \hat{x} , the vector $a_i(\hat{x})$ is orthogonal (normal) to the iso-value contour of $c_i(\hat{x})$ passing through \hat{x} ; this relationship is illustrated for a two-dimensional function in Figure 2.

Figure 2
Please see figure in printed Reference Manual

The matrix whose columns are the vectors $\{a_i\}$ is termed the matrix of constraint normals. Note that if $c_i(x)$ is a linear constraint involving x , then its vector of first partial derivatives is simply the vector a_i .

2.3. Sufficient Conditions for a Solution

All nonlinear functions will be assumed to have continuous second derivatives in the neighbourhood of the solution.

2.3.1. Unconstrained minimization

The following conditions are sufficient for the point x^* to be an unconstrained local minimum of $F(x)$:

(i) $\|g(x^*)\| = 0$; and

(ii) $G(x^*)$ is positive-definite,

where $\|g\|$ denotes the Euclidean length of g .

*
At a solution x^* , of a linearly-constrained problem, the constraints which hold as equalities are called the active or binding constraints. Assume that there are t active constraints
*
at the solution x^* , and let A denote the matrix whose columns are

the columns of A corresponding to the active constraints, with \hat{b} the vector similarly obtained from b ; then

$$\hat{A}^T \hat{x} = \hat{b}.$$

The matrix Z is defined as an n by $(n-t)$ matrix satisfying:

$$\hat{A}^T Z = 0; \quad Z^T Z = I.$$

The columns of Z form an orthogonal basis for the set of vectors orthogonal to the columns of A .

Define

$$\hat{g}_Z(x) = Z^T \nabla F(x), \text{ the projected gradient vector of } F(x);$$

$$\hat{G}_Z(x) = Z^T \nabla^2 F(x) Z, \text{ the projected Hessian matrix of } F(x).$$

At the solution of a linearly-constrained problem, the projected gradient vector must be zero, which implies that the gradient

vector $\hat{g}(x)$ can be written as a linear combination of the

columns of A , i.e., $\hat{g}(x) = \sum_{i=1}^t (\lambda_i) \hat{a}_i = A(\lambda)$. The scalar

$(\lambda)_i$ is defined as the Lagrange multiplier corresponding to the i th active constraint. A simple interpretation of the i th Lagrange multiplier is that it gives the gradient of $F(x)$ along the i th active constraint normal; a convenient definition of the Lagrange multiplier vector (although not a recommended method for computation) is:

$$(\lambda) = (A^T A)^{-1} A^T \hat{g}(x).$$

*

Sufficient conditions for x^* to be the solution of a linearly-constrained problem are:

- (i) x^* is feasible, and $A^T x^* = b$; and
- (ii) $\|g(x^*)\|_Z = 0$, or equivalently, $g(x^*) = A(\lambda)$; and
- (iii) $G(x^*)$ is positive-definite; and
- (iv) $(\lambda)_i > 0$ if $(\lambda)_i$ corresponds to a constraint $a_i^T x \geq b_i$;
 $(\lambda)_i < 0$ if $(\lambda)_i$ corresponds to a constraint $a_i^T x \leq b_i$.

The sign of $(\lambda)_i$ is immaterial for equality constraints, which by definition are always active.

2.3.4. Nonlinearly-constrained minimization

For nonlinearly-constrained problems, much of the terminology is defined exactly as in the linearly-constrained case. The set of active constraints at x again means the set of constraints that hold as equalities at x , with corresponding definitions of c and A : the vector $c(x)$ contains the active constraint functions, and the columns of $A(x)$ are the gradient vectors of the active constraints. As before, Z is defined in terms of $A(x)$ as a matrix such that:

$$\begin{matrix} \hat{A}^T & & T \\ A^T Z=0; & & Z^T Z=I \end{matrix}$$

where the dependence on x has been suppressed for compactness.

The projected gradient vector $\hat{g}(x)$ is the vector $Z^T g(x)$. At the

solution x^* of a nonlinearly-constrained problem, the projected gradient must be zero, which implies the existence of Lagrange multipliers corresponding to the active constraints, i.e.,

$$\hat{g}(x^*) = A(x^*)(\lambda).$$

The Lagrangian function is given by:

$$L(x, (\lambda)) = F(x) - (\lambda)^T c(x).$$

We define $\hat{g}_L(x)$ as the gradient of the Lagrangian function; $G_L(x)$

as its Hessian matrix, and $\hat{G}_L(x)$ as its projected Hessian matrix,

$$\text{i.e., } \hat{G}_L = Z^T G_L Z.$$

Sufficient conditions for x^* to be a solution of nonlinearly-constrained problem are:

(i) x^* is feasible, and $c(x^*)=0$; and

(ii) $\| \hat{g}_L(x^*) \| = 0$, or, equivalently, $\hat{g}(x^*) = A(x^*)(\lambda)$; and

(iii) $\hat{G}_L(x^*)$ is positive-definite; and

(iv) $(\lambda_i) > 0$ if (λ_i) corresponds to a constraint of the form $c_i \geq 0$; the sign of (λ_i) is immaterial for an equality constraint.

Note that condition (ii) implies that the projected gradient of the Lagrangian function must also be zero at x^* , since the application of Z^T annihilates the matrix $A(x^*)$.

2.4. Background to Optimization Methods

All the algorithms contained in this Chapter generate an iterative sequence $\{x^{(k)}\}$ that converges to the solution x^* in the limit, except for some special problem categories (i.e., linear and quadratic programming). To terminate computation of the sequence, a convergence test is performed to determine whether the current estimate of the solution is an adequate approximation. The convergence tests are discussed in Section 2.6

Most of the methods construct a sequence $\{x^{(k)}\}$ satisfying:

$$x^{(k+1)} = x^{(k)} + (\alpha^{(k)}) p^{(k)},$$

where the vector $p^{(k)}$ is termed the direction of search, and $(\alpha^{(k)})$ is the steplength. The steplength $(\alpha^{(k)})$ is chosen so that $F(x^{(k+1)}) < F(x^{(k)})$.

2.4.1. Methods for unconstrained optimization

The distinctions among methods arise primarily from the need to use varying levels of information about derivatives of $F(x)$ in defining the search direction. We describe three basic approaches to unconstrained problems, which may be extended to other problem categories. Since a full description of the methods would fill several volumes, the discussion here can do little more than

allude to the processes involved, and direct the reader to other sources for a full explanation.

(a) Newton-type Methods (Modified Newton Methods)

Newton-type methods use the Hessian matrix $G(x^{(k)})$, or a finite difference approximation to $G(x^{(k)})$, to define the search direction. The routines in the Library either require a subroutine that computes the elements of $G(x^{(k)})$, or they approximate $G(x^{(k)})$ by finite differences.

Newton-type methods are the most powerful methods available for general problems and will find the minimum of a quadratic function in one iteration. See Sections 4.4. and 4.5.1. of Gill et al [5].

(b) Quasi-Newton Methods

Quasi-Newton methods approximate the Hessian $G(x^{(k)})$ by a matrix $B^{(k)}$ which is modified at each iteration to include information obtained about the curvature of F along the latest search direction. Although not as robust as Newton-type methods, quasi-Newton methods can be more efficient because $G(x^{(k)})$ is not computed, or approximated by finite-differences. Quasi-Newton methods minimize a quadratic function in n iterations. See Section 4.5.2 of Gill et al [5].

(c) Conjugate-Gradient Methods

Unlike Newton-type and quasi-Newton methods, conjugate gradient methods do not require the storage of an n by n matrix and so are ideally suited to solve large problems. Conjugate-gradient type methods are not usually as reliable or efficient as Newton-type, or quasi-Newton methods. See Section 4.8.3 of Gill et al [5].

2.4.2. Methods for nonlinear least-squares problems

These methods are similar to those for unconstrained optimization, but exploit the special structure of the Hessian matrix to give improved computational efficiency.

Since

$$F(x) = \sum_{i=1}^m \frac{1}{2} f_i(x)$$

the Hessian matrix $G(x)$ is of the form

$$G(x) = 2 \left[J(x)^T J(x) + \sum_{i=1}^m f_i(x) G_i(x) \right],$$

where $J(x)$ is the Jacobian matrix of $f(x)$, and $G_i(x)$ is the Hessian matrix of $f_i(x)$.

In the neighbourhood of the solution, $||f(x)||$ is often small

compared to $||J(x)^T J(x)||$ (for example, when $f(x)$ represents the goodness of fit of a nonlinear model to observed data). In

such cases, $2J(x)^T J(x)$ may be an adequate approximation to $G(x)$, thereby avoiding the need to compute or approximate second derivatives of $\{f_i(x)\}$. See Section 4.7 of Gill et al [5].

2.4.3. Methods for handling constraints

Bounds on the variables are dealt with by fixing some of the variables on their bounds and adjusting the remaining free variables to minimize the function. By examining estimates of the Lagrange multipliers it is possible to adjust the set of variables fixed on their bounds so that eventually the bounds active at the solution should be correctly identified. This type of method is called an active set method. One feature of such methods is that, given an initial feasible point, all

(k)

approximations x are feasible. This approach can be extended to general linear constraints. At a point, x , the set of constraints which hold as equalities being used to predict, or approximate, the set of active constraints is called the working set.

Nonlinear constraints are more difficult to handle. If at all possible, it is usually beneficial to avoid including nonlinear constraints during the formulation of the problem. The methods currently implemented in the Library handle nonlinearly constrained problems either by transforming them into a sequence of bound constraint problems, or by transforming them into a sequence of quadratic programming problems. A feature of almost

(k)

all methods for nonlinear constraints is that x is not guaranteed to be feasible except in the limit, and this is certainly true of the routines currently in the Library. See Chapter 6, particularly Section 6.4 and Section 6.5 of Gill et al [5].

Anyone interested in a detailed description of methods for optimization should consult the references.

2.5. Scaling

Scaling (in a broadly defined sense) often has a significant influence on the performance of optimization methods. Since convergence tolerances and other criteria are necessarily based on an implicit definition of 'small' and 'large', problems with unusual or unbalanced scaling may cause difficulties for some algorithms. Nonetheless, there are currently no scaling routines in the Library, although the position is under constant review. In light of the present state of the art, it is considered that sensible scaling by the user is likely to be more effective than any automatic routine. The following sections present some general comments on problem scaling.

2.5.1. Transformation of variables

One method of scaling is to transform the variables from their original representation, which may reflect the physical nature of the problem, to variables that have certain desirable properties in terms of optimization. It is generally helpful for the following conditions to be satisfied:

- (i) the variables are all of similar magnitude in the region of interest;
- (ii) a fixed change in any of the variables results in similar changes in $F(x)$. Ideally, a unit change in any variable produces a unit change in $F(x)$;
- (iii) the variables are transformed so as to avoid cancellation error in the evaluation of $F(x)$.

Normally, users should restrict themselves to linear transformations of variables, although occasionally nonlinear transformations are possible. The most common such transformation (and often the most appropriate) is of the form

$$\begin{matrix} x & =Dx \\ \text{new} & \text{old} \end{matrix} ,$$

where D is a diagonal matrix with constant coefficients. Our experience suggests that more use should be made of the transformation

$$\begin{matrix} x & =Dx & +v, \\ \text{new} & \text{old} \end{matrix}$$

where v is a constant vector.

Consider, for example, a problem in which the variable x_3 represents the position of the peak of a Gaussian curve to be fitted to data for which the extreme values are 150 and 170; therefore x_3 is known to lie in the range 150--170. One possible

scaling would be to define a new variable x_3 , given by

$$x_3 = \frac{x_3 - 150}{170 - 150}.$$

A better transformation, however, is given by defining x as

$$x = \frac{x - 160}{3 \cdot 10}.$$

Frequently, an improvement in the accuracy of evaluation of $F(x)$ can result if the variables are scaled before the routines to evaluate $F(x)$ are coded. For instance, in the above problem just mentioned of Gaussian curve fitting, x may always occur in terms

of the form $(x - x_m)^3$, where x_m is a constant representing the mean peak position.

2.5.2. Scaling the objective function

The objective function has already been mentioned in the discussion of scaling the variables. The solution of a given problem is unaltered if $F(x)$ is multiplied by a positive constant, or if a constant value is added to $F(x)$. It is generally preferable for the objective function to be of the order of unity in the region of interest; thus, if in the original formulation $F(x)$ is always of the order of 10^{+5} (say),

then the value of $F(x)$ should be multiplied by 10^{-5} when evaluating the function within the optimization routines. If a constant is added or subtracted in the computation of $F(x)$, usually it should be omitted - i.e., it is better to formulate $F(x)$ as $x_1^2 + x_2^2$ rather than as $x_1^2 + x_2^2 + 1000$ or even $x_1^2 + x_2^2 + 1$. The inclusion of such a constant in the calculation of $F(x)$ can result in a loss of significant figures.

2.5.3. Scaling the constraints

The solution of a nonlinearly-constrained problem is unaltered if the i th constraint is multiplied by a positive weight w_i . At the approximation of the solution determined by a Library routine, the active constraints will not be satisfied exactly, but will

have 'small' values (for example, $c_1 = 10$, $c_2 = 10$, etc.). In general, this discrepancy will be minimized if the constraints are weighted so that a unit change in x produces a similar change in each constraint.

A second reason for introducing weights is related to the effect of the size of the constraints on the Lagrange multiplier estimates and, consequently, on the active set strategy. Additional discussion is given in Gill et al [5].

2.6. Analysis of Computed Results

2.6.1. Convergence criteria

The convergence criteria inevitably vary from routine to routine, since in some cases more information is available to be checked (for example, is the Hessian matrix positive-definite?), and different checks need to be made for different problem categories (for example, in constrained minimization it is necessary to verify whether a trial solution is feasible). Nonetheless, the underlying principles of the various criteria are the same; in non-mathematical terms, they are:

- (i) $\{x^{(k)}\}$ is the sequence $\{x^{(k)}\}$ converging?
- (ii) $\{F^{(k)}\}$ is the sequence $\{F^{(k)}\}$ converging?
- (iii) are the necessary and sufficient conditions for the solution satisfied?

The decision as to whether a sequence is converging is necessarily speculative. The criterion used in the present routines is to assume convergence if the relative change occurring between two successive iterations is less than some prescribed quantity. Criterion (iii) is the most reliable but often the conditions cannot be checked fully because not all the required information may be available.

2.6.2. Checking results

Little a priori guidance can be given as to the quality of the solution found by a nonlinear optimization algorithm, since no guarantees can be given that the methods will always work.

Therefore, it is necessary for the user to check the computed solution even if the routine reports success. Frequently a 'solution' may have been found even when the routine does not report a success. The reason for this apparent contradiction is that the routine needs to assess the accuracy of the solution. This assessment is not an exact process and consequently may be unduly pessimistic. Any 'solution' is in general only an approximation to the exact solution, and it is possible that the accuracy specified by the user is too stringent.

Further confirmation can be sought by trying to check whether or not convergence tests are almost satisfied, or whether or not some of the sufficient conditions are nearly satisfied. When it is thought that a routine has returned a non-zero value of IFAIL only because the requirements for 'success' were too stringent it may be worth restarting with increased convergence tolerances.

For nonlinearly-constrained problems, check whether the solution returned is feasible, or nearly feasible; if not, the solution returned is not an adequate solution.

Confidence in a solution may be increased by resolving the problem with a different initial approximation to the solution. See Section 8.3 of Gill et al [5] for further information.

2.6.3. Monitoring progress

Many of the routines in the Chapter have facilities to allow the user to monitor the progress of the minimization process, and users are encouraged to make use of these facilities. Monitoring information can be a great aid in assessing whether or not a satisfactory solution has been obtained, and in indicating difficulties in the minimization problem or in the routine's ability to cope with the problem.

The behaviour of the function, the estimated solution and first derivatives can help in deciding whether a solution is acceptable and what to do in the event of a return with a non-zero value of IFAIL.

2.6.4. Confidence intervals for least-squares solutions

When estimates of the parameters in a nonlinear least-squares problem have been found, it may be necessary to estimate the variances of the parameters and the fitted function. These can be calculated from the Hessian of $F(x)$ at the solution.

In many least-squares problems, the Hessian is adequately approximated at the solution by $G = 2J^T J$ (see Section 2.4.3). The Jacobian, J , or a factorization of J is returned by all the comprehensive least-squares routines and, in addition, a routine is supplied in the Library to estimate variances of the parameters following the use of most of the nonlinear least-squares routines, in the case that $G = 2J^T J$ is an adequate approximation.

Let H be the inverse of G , and S be the sum of squares, both

calculated at the solution x ; an unbiased estimate of the variance of the i th parameter x_i is

$$\text{var } x_i = \frac{2S}{m-n} H_{ii}$$

and an unbiased estimate of the covariance of x_i and x_j is

$$\text{covar}(x_i, x_j) = \frac{2S}{m-n} H_{ij}$$

If x^* is the true solution, then the $100(1-(\beta))$ confidence

interval on x_i is

$$x_i - \frac{\sqrt{\text{var } x_i} \cdot t_{(1-(\beta)/2, m-n)}}{1} \leq x_i \leq x_i + \frac{\sqrt{\text{var } x_i} \cdot t_{(1-(\beta)/2, m-n)}}{1}$$

$$+ \frac{1}{\sqrt{\sum_{i=1}^n \text{var } x_i \cdot t_{(1-(\beta)/2, m-n)}}}, \quad i=1,2,\dots,n$$

where $t_{(1-(\beta)/2, m-n)}$ is the 100(1-(beta))/2 percentage point of the t-distribution with m-n degrees of freedom.

In the majority of problems, the residuals f_i , for $i=1,2,\dots,m$, contain the difference between the values of a model function $(\phi)(z,x)$ calculated for m different values of the independent variable z, and the corresponding observed values at these points. The minimization process determines the parameters, or

constants x, of the fitted function $(\phi)(z,x)$. For any value, z, of the independent variable z, an unbiased estimate of the variance of (ϕ) is

$$\text{var } (\phi) = \frac{2S}{m-n} = \frac{\sum_{i=1}^n \sum_{j=1}^n \left[\frac{d^2(\phi)}{dx_i dx_j} \right] H_{ij}}{\sum_{i=1}^n \sum_{j=1}^n \left[\frac{d^2(\phi)}{dx_i dx_j} \right] H_{ij}}$$

The 100(1-(beta)) confidence interval on F at the point z is

$$(\phi)(z,x) - \frac{t_{(1-(\beta)/2, m-n)}}{\sqrt{\text{var } (\phi)}} < (\phi)(z,x) < (\phi)(z,x) + \frac{t_{(1-(\beta)/2, m-n)}}{\sqrt{\text{var } (\phi)}}.$$

For further details on the analysis of least-squares solutions see Bard [1] and Wolberg [7].

3. Recommendations on Choice and Use of Routines

The choice of routine depends on several factors: the type of problem (unconstrained, etc.); the level of derivative information available (function values only, etc.); the experience of the user (there are easy-to-use versions of some routines); whether or not storage is a problem; and whether computational time has a high priority.

3.1. Choice of Routine

Routines are provided to solve the following types of problem:

Nonlinear Programming	E04UCF
Quadratic Programming	E04NAF
Linear Programming	E04MBF
Nonlinear Function (using 1st derivatives)	E04DGF
Nonlinear Function, unconstrained or simple bounds (using function values only)	E04JAF
Nonlinear least-squares (using function values only)	E04FDF
Nonlinear least-squares (using function values and 1st derivatives)	E04GCF

E04UCF can be used to solve unconstrained, bound-constrained and

linearly-constrained problems.

E04NAF can be used as a comprehensive linear programming solver; however, in most cases the easy-to-use routine E04MBF will be adequate.

E04MBF can be used to obtain a feasible point for a set of linear constraints.

E04DGF can be used to solve large scale unconstrained problems.

The routines can be used to solve problems in a single variable.

3.2. Service Routines

One of the most common errors in use of optimization routines is that the user's subroutines incorrectly evaluate the relevant partial derivatives. Because exact gradient information normally enhances efficiency in all areas of optimization, the user should be encouraged to provide analytical derivatives whenever possible. However, mistakes in the computation of derivatives can result in serious and obscure run-time errors, as well as complaints that the Library routines are incorrect.

E04UCF incorporates a check on the gradients being supplied and users are encouraged to utilize this option; E04GCF also incorporates a call to a derivative checker.

E04YCF estimates selected elements of the variance-covariance matrix for the computed regression parameters following the use of a nonlinear least-squares routine.

3.3. Function Evaluations at Infeasible Points

Users must not assume that the routines for constrained problems will require the objective function to be evaluated only at points which satisfy the constraints, i.e., feasible points. In the first place some of the easy-to-use routines call a service routine which will evaluate the objective function at the user-supplied initial point, and at neighbouring points (to check user-supplied derivatives or to estimate intervals for finite differencing). Apart from this, all routines will ensure that any evaluations of the objective function occur at points which approximately satisfy any simple bounds or linear constraints. Satisfaction of such constraints is only approximate because:

- (a) routines which have a parameter FEATOL may allow such constraints to be violated by a margin specified by FEATOL;
- (b) routines which estimate derivatives by finite differences may require function evaluations at points which just violate such constraints even though the current iteration just satisfies them.

There is no attempt to ensure that the current iteration satisfies any nonlinear constraints. Users who wish to prevent their objective function being evaluated outside some known region (where it may be undefined or not practically computable), may try to confine the iteration within this region by imposing suitable simple bounds or linear constraints (but beware as this may create new local minima where these constraints are active).

Note also that some routines allow the user-supplied routine to return a parameter (MODE) with a negative value to force an immediate clean exit from the minimization when the objective function cannot be evaluated.

3.4. Related Problems

Apart from the standard types of optimization problem, there are other related problems which can be solved by routines in this or other chapters of the Library.

E04MBF can be used to find a feasible point for a set of linear constraints and simple bounds.

Two routines in Chapter F04 solve linear least-squares problems,

$$\text{i.e., minimize } \sum_{i=1}^m r_i(x)^2 \text{ where } r_i(x) = b_i - \sum_{j=1}^n a_{ij} x_j.$$

E02GAF solves an overdetermined system of linear equations in the

$$\text{1 norm, i.e., minimizes } \sum_{i=1}^m |r_i(x)|, \text{ with } r \text{ as above.}$$

E04 -- Minimizing or Maximizing a Function E04DGF
 E04DGF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details.

The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

Note for users via the AXIOM system: the interface to this routine has been enhanced for use with AXIOM and is slightly different to that offered in the standard version of the Foundation Library. In particular, the optional parameters of the NAG routine are now included in the parameter list. These are described in section 5.1.2, below.

1. Purpose

E04DGF minimizes an unconstrained nonlinear function of several variables using a pre-conditioned, limited memory quasi-Newton conjugate gradient method. First derivatives are required. The routine is intended for use on large scale problems.

2. Specification

```

SUBROUTINE E04DGF(N,OBJFUN,ITER,OBJF,OBJGRD,X,IWORK,WORK,IUSER,

3. Description

E04DGF uses a pre-conditioned conjugate gradient method and is based upon algorithm PLMA as described in Gill and Murray [1] and Gill et al [2] Section 4.8.3.

The algorithm proceeds as follows:

Let x_0 be a given starting point and let k denote the current iteration, starting with $k=0$. The iteration requires g_k , the gradient vector evaluated at x_k , the k th estimate of the minimum. At each iteration a vector p_k (known as the direction of search) is computed and the new estimate x_{k+1} is given by $x_k + (\alpha) p_k$

where $(\alpha)_k$ (the step length) minimizes the function $F(x_k + (\alpha)_k p_k)$ with respect to the scalar $(\alpha)_k$. A choice of initial step $(\alpha)_0$ is taken as

$$(\alpha)_0 = \min\{1, 2|F_{\text{est}} - F_k|/g_k^T g_k\}$$

where F_{est} is a user-supplied estimate of the function value at the solution. If F_{est} is not specified, the software always chooses the unit step length for $(\alpha)_0$. Subsequent step length estimates are computed using cubic interpolation with safeguards.

A quasi-Newton method can be used to compute the search direction p_k by updating the inverse of the approximate Hessian $(H)_k$ and computing

$$p_{k+1} = -H_{k+1} g_{k+1} \quad (1)$$

The updating formula for the approximate inverse is given by

$$H_{k+1} = H_k - \frac{1}{y_k^T s_k} (H_k y_k s_k^T + s_k y_k^T H_k) + \frac{1}{y_k^T s_k} (1 + \frac{y_k^T H_k y_k}{y_k^T s_k}) s_k s_k^T \quad (2)$$

where $y_k = g_k - g_{k-1}$ and $s_k = x_{k+1} - x_k = (\alpha)_k p_k$.

The method used by E04DGF to obtain the search direction is based upon computing p_{k+1} as $-H_{k+1} g_{k+1}$ where H_{k+1} is a matrix obtained by updating the identity matrix with a limited number of quasi-Newton corrections. The storage of an n by n matrix is avoided by

storing only the vectors that define the rank two corrections - hence the term limited-memory quasi-Newton method. The precise method depends upon the number of updating vectors stored. For example, the direction obtained with the 'one-step' limited memory update is given by (1) using (2) with H_k equal to the

identity matrix, viz.

$$p_{k+1} = -g_{k+1} + \frac{1}{T_{k,k+1}} (s_{k+1}^T y_{k+1} + y_{k+1}^T g_{k+1} - s_{k+1}^T g_{k+1}) - \frac{(1 + \frac{s_{k+1}^T y_{k+1}}{y_{k+1}^T s_{k+1}})}{T_{k,k+1}} s_{k+1}$$

E04DGF uses a two-step method described in detail in Gill and Murray [1] in which restarts and pre-conditioning are incorporated. Using a limited-memory quasi-Newton formula, such as the one above, guarantees p_{k+1} to be a descent direction if

all the inner products $y_k^T s_k$ are positive for all vectors y_k and s_k used in the updating formula.

The termination criterion of E04DGF is as follows:

Let (τ) specify a parameter that indicates the number of correct figures desired in F_k ((τ) is equivalent to Optimality Tolerance in the optional parameter list, see Section 5.1). If the following three conditions are satisfied

$$(i) \quad F_{k-1} - F_k < (\tau) (1 + |F_k|)$$

$$(ii) \quad \|x_{k-1} - x_k\| < \frac{1}{\sqrt{F_k}} (\tau) (1 + \|x_k\|)$$

$$(iii) \quad \|g_k\| \leq \frac{3}{\sqrt{F_k}} (\tau) (1 + |F_k|) \text{ or } \|g_k\| < (\text{epsilon})_A,$$

where $(\text{epsilon})_A$ is the absolute error associated with A

computing the objective function

then the algorithm is considered to have converged. For a full discussion on termination criteria see Gill et al [2] Chapter 8.

5. Parameters

1: N -- INTEGER Input
 On entry: the number n of variables. Constraint: N >= 1.

2: OBJFUN -- SUBROUTINE, supplied by the user. External Procedure
 OBJFUN must calculate the objective function F(x) and its gradient for a specified n element vector x.

Its specification is:

```
SUBROUTINE OBJFUN (MODE, N, X, OBJF, OBJGRD,
1                 NSTATE, IUSER, USER)
  INTEGER          MODE, N, NSTATE, IUSER(*)
  DOUBLE PRECISION X(N), OBJF, OBJGRD(N), USER(*)
```

1: MODE -- INTEGER Input/Output
 MODE is a flag that the user may set within OBJFUN to indicate a failure in the evaluation of the objective function. On entry: MODE is always non-negative. On exit: if MODE is negative the execution of E04DGF is terminated with IFAIL set to MODE.

2: N -- INTEGER Input
 On entry: the number n of variables.

3: X(N) -- DOUBLE PRECISION array Input
 On entry: the point x at which the objective function is required.

4: OBJF -- DOUBLE PRECISION Output

On exit: the value of the objective function F at the current point x .

5: OBJGRD(N) -- DOUBLE PRECISION array Output
 ddF
 On exit: OBJGRD(i) must contain the value of ---- at
 ddx
 i
 the point x , for $i=1,2,\dots,n$.

6: NSTATE -- INTEGER Input
 On entry: NSTATE will be 1 on the first call of OBJFUN by E04DGF, and is 0 for all subsequent calls. Thus, if the user wishes, NSTATE may be tested within OBJFUN in order to perform certain calculations once only. For example the user may read data or initialise COMMON blocks when NSTATE = 1.

7: IUSER(*) -- INTEGER array User Workspace

8: USER(*) -- DOUBLE PRECISION array User Workspace
 OBJFUN is called from E04DGF with the parameters IUSER and USER as supplied to E04DGF. The user is free to use arrays IUSER and USER to supply information to OBJFUN as an alternative to using COMMON.

OBJFUN must be declared as EXTERNAL in the (sub)program from which E04DGF is called. Parameters denoted as Input must not be changed by this procedure.

3: ITER -- INTEGER Output
 On exit: the number of iterations performed.

4: OBJF -- DOUBLE PRECISION Output
 On exit: the value of the objective function $F(x)$ at the final iterate.

5: OBJGRD(N) -- DOUBLE PRECISION array Output
 On exit: the objective gradient at the final iterate.

6: X(N) -- DOUBLE PRECISION array Input/Output
 On entry: an initial estimate of the solution. On exit: the final estimate of the solution.

7: IWORK(N+1) -- INTEGER array Workspace

8: WORK(13*N) -- DOUBLE PRECISION array Workspace

9: IUSER(*) -- INTEGER array User Workspace
 Note: the dimension of the array IUSER must be at least 1.
 This array is not used by E04DGF, but is passed directly to
 routine OBJFUN and may be used to supply information to
 OBJFUN.

10: USER(*) -- DOUBLE PRECISION array User Workspace
 Note: the dimension of the array USER must be at least 1.
 This array is not used by E04DGF, but is passed directly to
 routine OBJFUN and may be used to supply information to
 OBJFUN.

11: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. Users who are
 unfamiliar with this parameter should refer to the Essential
 Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or
 gives a warning (see Section 6).

For this routine, because the values of output parameters
 may be useful even if IFAIL \neq 0 on exit, users are
 recommended to set IFAIL to -1 before entry. It is then
 essential to test the value of IFAIL on exit.

5.1. Optional Input Parameters

Several optional parameters in E04DGF define choices in the
 behaviour of the routine. In order to reduce the number of formal
 parameters of E04DGF these optional parameters have associated
 default values (see Section 5.1.3) that are appropriate for most
 problems. Therefore the user need only specify those optional
 parameters whose values are to be different from their default
 values.

The remainder of this section can be skipped by users who wish to
 use the default values for all optional parameters. A complete
 list of optional parameters and their default values is given in
 Section 5.1.3.

5.1.1. Specification of the Optional Parameters

Optional parameters may be specified by calling one, or both, of
 E04DJF and E04DKF prior to a call to E04DGF.

E04DJF reads options from an external options file, with Begin and End as the first and last lines respectively and each intermediate line defining a single optional parameter. For example,

```
Begin
  Print Level = 1
End
```

The call

```
CALL E04DJF(IOPTNS, INFORM)
```

can then be used to read the file on unit IOPTNS. INFORM will be zero on successful exit. E04DJF should be consulted for a full description of this method of supplying optional parameters.

E04DKF can be called to supply options directly, one call being necessary for each optional parameter.

For example,

```
CALL E04DKF('Print level = 1')
```

E04DKF should be consulted for a full description of this method of supplying optional parameters.

All optional parameters not specified by the user are set to their default values. Optional parameters specified by the user are unaltered by E04DGF (unless they define invalid values) and so remain in effect for subsequent calls to E04DGF, unless altered by the user.

5.1.2. Description of the Optional Parameters

The following list (in alphabetical order) gives the valid options. For each option, we give the keyword, any essential optional qualifiers, the default value, and the definition. The minimum valid abbreviation of each keyword is underlined. If no characters of an optional qualifier are underlined, the qualifier may be omitted. The letter a denotes a phrase (character string) that qualifies an option. The letters i and r denote INTEGER and real values required with certain options. The number (epsilon)

is a generic notation for machine precision, and (ϵ) ^R denotes the relative precision of the objective function (the optional parameter Function Precision; see below).

Defaults

This special keyword may be used to reset the default values following a call to E04DGF.

Estimated Optimal Function Value r

(Axiom parameter ES)

This value of r specifies the user-supplied guess of the optimum objective function value. This value is used by E04DGF to calculate an initial step length (see Section 3). If the value of r is not specified by the user (the default), then this has the effect of setting the initial step length to unity. It should be noted that for badly scaled functions a unit step along the steepest descent direction will often compute the function at very large values of x .

0.9

Function Precision r Default = (ϵ)

(Axiom parameter FU)

The parameter defines (ϵ) , which is intended to be a

measure of the accuracy with which the problem function F can be computed. The value of (ϵ) should reflect the relative

precision of $1+|F(x)|$; i.e. (ϵ) acts as a relative

precision when $|F|$ is large, and as an absolute precision when $|F|$ is small. For example, if $F(x)$ is typically of order 1000 and the first six significant digits are known to be correct, an appropriate value for (ϵ) would be $1.0\text{E}-6$. In contrast, if

^R
-4

$F(x)$ is typically of order 10^{-4} and the first six significant digits are known to be correct, an appropriate value for (ϵ) would be $1.0\text{E}-10$. The choice of (ϵ) can be

^R quite complicated for badly scaled problems; see Chapter 8 of ^R

Gill and Murray [2], for a discussion of scaling techniques. The default value is appropriate for most simple functions that are computed with full accuracy. However when the accuracy of the computed function values is known to be significantly worse than full precision, the value of (epsilon) should be large enough so

R

that E04DGF will not attempt to distinguish between function values that differ by less than the error inherent in the calculation. If $0 \leq r < (\text{epsilon})$, where (epsilon) is the machine precision then the default value is used.

Iteration Limit i Default = max(50,5n)

Iters

Itns

(Axiom parameter IT)

The value i ($i \geq 0$) specifies the maximum number of iterations allowed before termination. If $i < 0$ the default value is used. See Section 8 for further information.

Linesearch Tolerance r Default = 0.9

(Axiom parameter LIN)

The value r ($0 \leq r < 1$) controls the accuracy with which the step (alpha) taken during each iteration approximates a minimum of the function along the search direction (the smaller the value of r, the more accurate the linesearch). The default value $r=0.9$ requests an inaccurate search, and is appropriate for most problems. A more accurate search may be appropriate when it is desirable to reduce the number of iterations - for example, if the objective function is cheap to evaluate.

List Default = List

Nolist

(Axiom parameter LIST)

Normally each optional parameter specification is printed as it is supplied. Nolist may be used to suppress the printing and List may be used to restore printing.

10

Maximum Step Length r Default = 10

(Axiom parameter MA)

The value r ($r > 0$) defines the maximum allowable step length for the line search. If $r \leq 0$ the default value is used.

0.8

Optimality Tolerance r Default = (epsilon)

(Axiom parameter OP)

R

The parameter r ((epsilon) $\leq r < 1$) specifies the accuracy to which

R

the user wishes the final iterate to approximate a solution of the problem. Broadly speaking, r indicates the number of correct figures desired in the objective function at the solution. For

- 6

example, if r is 10 and E04DGF terminates successfully, the final value of F should have approximately six correct figures. E04DGF will terminate successfully if the iterative sequence of x -values is judged to have converged and the final point satisfies the termination criteria (see Section 3, where (tau) represents

F

Optimality Tolerance).

Print Level i Default = 10

(Axiom parameter PR)

The value i controls the amount of printout produced by E04DGF. The following levels of printing are available.

i Output.

0 No output.

1 The final solution.

5 One line of output for each iteration.

10 The final solution and one line of output for each iteration.

Start Objective Check at Variable i Default = 1

(Axiom parameter STA)

Stop Objective Check at Variable i Default = n

(Axiom parameter STO)

These keywords take effect only if Verify Level > 0 (see below). They may be used to control the verification of gradient elements computed by subroutine OBJFUN. For example if the first 30 variables appear linearly in the objective, so that the corresponding gradient elements are constant, then it is reasonable to specify Start Objective Check at Variable 31.

Verify Level i Default = 0

Verify No

Verify Level -1

Verify Level 0

Verify

Verify Yes

Verify Objective Gradients

Verify Gradients

Verify Level 1

(Axiom parameter VE)

These keywords refer to finite-difference checks on the gradient elements computed by the user-provided subroutine OBJFUN. It is possible to set Verify Level in several ways, as indicated above. For example, the gradients will be verified if Verify, Verify Yes, Verify Gradients, Verify Objective Gradients or Verify Level = 1 is specified.

If $i < 0$ then no checking will be performed. If $i > 0$ then the gradients will be verified at the user-supplied point. If $i = 0$ only a 'cheap' test will be performed, requiring one call to OBJFUN. If $i = 1$, a more reliable (but more expensive) check will be made on individual gradient components, within the ranges specified by the Start and Stop keywords as described above. A

result of the form OK or BAD? is printed by E04DGF to indicate whether or not each component appears to be correct.

5.1.3. Optional parameter checklist and default values

For easy reference, the following sample list shows all valid keywords and their default values. The default options Function Precision and Optimality Tolerance depend upon (epsilon), the machine precision.

Optional Parameters	Default Values
Estimated Optimal Function Value	
Function precision	0.9 (epsilon)
Iterations	max(50,5n)
Linesearch Tolerance	0.9
Maximum Step Length	10 10
List/Nolist	List
Optimality Tolerance	0.8 (epsilon)
Print Level	10
Start Objective Check at Variable	1
Stop Objective Check at Variable	n
Verify Level	0

5.2. Description of Printed Output

The level of printed output from E04DGF is controlled by the user (see the description of Print Level in Section 5.1).

When Print Level ≥ 5 , the following line of output is produced

at each iteration.

Itn is the iteration count.

Step is the step (alpha) taken along the computed search direction. On reasonably well-behaved problems, the unit step will be taken as the solution is approached.

Nfun is the cumulated number of evaluations of the objective function needed for the linesearch. Evaluations needed for the estimation of the gradients by finite differences are not included. Nfun is printed as a guide to the amount of work required for the linesearch. E04DGF will perform at most 16 function evaluations per iteration.

Objective is the value of the objective function.

Norm G is the Euclidean norm of the gradient of the objective function.

Norm X is the Euclidean norm of x.

Norm $(X(k-1)-X(k))$ is the Euclidean norm of $x_{k-1} - x_k$.

When Print Level = 1 or Print Level ≥ 10 then the solution at the end of execution of E04DGF is printed out.

The following describes the printout for each variable:

Variable gives the name (VARBL) and index j (j = 1 to n) of the variable

Value is the value of the variable at the final iterate

Gradient Value is the value of the gradient of the objective function with respect to the jth variable at the final iterate

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are

output on the current error message unit (as defined by X04AAF).

On exit from E04DGF, IFAIL should be tested. If Print Level > 0 then a short description of IFAIL is printed.

Errors and diagnostics indicated by IFAIL from E04DGF are as follows:

IFAIL< 0

A negative value of IFAIL indicates an exit from E04DGF because the user set MODE negative in routine OBJFUN. The value of IFAIL will be the same as the user's setting of MODE.

IFAIL= 1

Not used by this routine.

IFAIL= 2

Not used by this routine.

IFAIL= 3

The maximum number of iterations has been performed. If the algorithm appears to be making progress the iterations value may be too small (see Section 5.1.2) so the user should increase iterations and rerun E04DGF. If the algorithm seems to be 'bogged down', the user should check for incorrect gradients or ill-conditioning as described below under IFAIL = 6.

IFAIL= 4

The computed upper bound on the step length taken during the linesearch was too small. A rerun with an increased value of the Maximum Step Length ((rho) say) may be successful unless
10
(rho)>=10 (the default value), in which case the current point cannot be improved upon.

IFAIL= 5

Not used by this routine.

IFAIL= 6

A sufficient decrease in the function value could not be attained during the final linesearch. If the subroutine OBJFUN computes the function and gradients correctly, then this may occur because an overly stringent accuracy has been requested, i.e., Optimality Tolerance is too small or if the

minimum lies close to a step length of zero. In this case the user should apply the four tests described in Section 3 to determine whether or not the final solution is acceptable (the user will need to set Print Level ≥ 5). For a discussion of attainable accuracy see Gill and Murray [2].

If many iterations have occurred in which essentially no progress has been made or E04DGF has failed to move from the initial point, subroutine OBJFUN may be incorrect. The user should refer to the comments below under IFAIL = 7 and check the gradients using the Verify parameter. Unfortunately, there may be small errors in the objective gradients that cannot be detected by the verification process. Finite-difference approximations to first derivatives are catastrophically affected by even small inaccuracies.

IFAIL= 7

Large errors were found in the derivatives of the objective function. This value of IFAIL will occur if the verification process indicated that at least one gradient component had no correct figures. The user should refer to the printed output to determine which elements are suspected to be in error.

As a first step, the user should check that the code for the objective values is correct - for example, by computing the function at a point where the correct value is known. However, care should be taken that the chosen point fully tests the evaluation of the function. It is remarkable how often the values $x=0$ or $x=1$ are used to test function evaluation procedures, and how often the special properties of these numbers make the test meaningless.

Special care should be used in this test if computation of the objective function involves subsidiary data communicated in COMMON storage. Although the first evaluation of the function may be correct, subsequent calculations may be in error because some of the subsidiary data has accidentally been overwritten.

Errors in programming the function may be quite subtle in that the function value is 'almost' correct. For example, the function may not be accurate to full precision because of the inaccurate calculation of a subsidiary quantity, or the limited accuracy of data upon which the function depends. A common error on machines where numerical

IFAIL= 8

The problem should be rerun at a different starting point.

On entry $N < 1$.

8. Further Comments

9. Example

$$F = e^{x^2} (4x^2 + 2x^2 + 4x^2 + x^2 + 2x^2 + 1).$$

%%%%%%%%%%

E04 -- Minimizing or Maximizing a Function E04DJF
E04DJF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

To supply optional parameters to E04DGF from an external file.

2. Specification

```
SUBROUTINE E04DJF (IOPTNS, INFORM)
  INTEGER          IOPTNS, INFORM
```

3. Description

E04DJF may be used to supply values for optional parameters to E04DGF. E04DJF reads an external file and each line of the file defines a single optional parameter. It is only necessary to supply values for those parameters whose values are to be different from their default values.

Each optional parameter is defined by a single character string of up to 72 characters, consisting of one or more items. The items associated with a given option must be separated by spaces, or equal signs (=). Alphabetic characters may be upper or lower case. The string

```
Print level = 1
```

is an example of a string used to set an optional parameter. For each option the string contains one or more of the following items:

- (a) A mandatory keyword.
- (b) A phrase that qualifies the keyword.
- (c) A number that specifies an INTEGER or real value. Such numbers may be up to 16 contiguous characters in Fortran 77's I, F, E or D formats, terminated by a space if this is not the last item on the line.

Blank strings and comments are ignored. A comment begins with an asterisk (*) and all subsequent characters in the string are regarded as part of the comment.

The file containing the options must start with begin and must finish with end. An example of a valid options file is:

```
Begin * Example options file
  Print level = 10
End
```

Normally each line of the file is printed as it is read, on the current advisory message unit (see X04ABF), but printing may be suppressed using the keyword nolist. To suppress printing of begin, nolist must be the first option supplied as in the file:

```
Begin
  Nolist
  Print level = 10
End
```

Printing will automatically be turned on again after a call to E04DGF and may be turned on again at any time by the user by using the keyword list.

Optional parameter settings are preserved following a call to E04DGF, and so the keyword defaults is provided to allow the user to reset all the optional parameters to their default values prior to a subsequent call to E04DGF.

A complete list of optional parameters, their abbreviations, synonyms and default values is given in Section 5.1 of the routine document for E04DGF.

4. References

None.

5. Parameters

- 1: IOPTNS -- INTEGER Input
 On entry: IOPTNS must be the unit number of the options file. Constraint: $0 \leq \text{IOPTNS} \leq 99$.

```

2:  INFORM -- INTEGER                                     Output
    On exit: INFORM will be zero if an options file with the
    correct structure has been read. Otherwise INFORM will be
    positive. Positive values of INFORM indicate that an options
    file may not have been successfully read as follows:
    INFORM = 1
              IOPTNS is not in the range [0,99].

    INFORM = 2
              begin was found, but end-of-file was found before end
              was found.

    INFORM = 3
              end-of-file was found before begin was found.

```

6. Error Indicators and Warnings

If a line is not recognised as a valid option, then a warning message is output on the current advisory message unit (see X04ABF).

7. Accuracy

Not applicable.

8. Further Comments

E04DKF may also be used to supply optional parameters to E04DGF.

9. Example

See the example for E04DGF.

%%%

```

E04 -- Minimizing or Maximizing a Function                E04DKF
      E04DKF -- NAG Foundation Library Routine Document

```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

To supply individual optional parameters to E04DGF.

2. Specification

```
SUBROUTINE E04DKF (STRING)
CHARACTER*(*)    STRING
```

3. Description

E04DKF may be used to supply values for optional parameters to E04DGF. It is only necessary to call E04DKF for those parameters whose values are to be different from their default values. One call to E04DKF sets one parameter value.

Each optional parameter is defined by a single character string of up to 72 characters, consisting of one or more items. The items associated with a given option must be separated by spaces, or equal signs (=). Alphabetic characters may be upper or lower case. The string

```
Print Level = 1
```

is an example of a string used to set an optional parameter. For each option the string contains one or more of the following items:

- (a) A mandatory keyword.
- (b) A phrase that qualifies the keyword.
- (c) A number that specifies an INTEGER or real value. Such numbers may be up to 16 contiguous characters in Fortran 77's I, F, E or D formats, terminated by a space if this is not the last item on the line.

Blank strings and comments are ignored. A comment begins with an asterisk (*) and all subsequent characters in the string are regarded as part of the comment.

Normally, each user-specified option is printed as it is defined, on the current advisory message unit (see X04ABF), but this printing may be suppressed using the keyword `nolist`. Thus the statement

```
CALL E04DKF ('Nolist')
```

suppresses printing of this and subsequent options. Printing will

automatically be turned on again after a call to E04DGF, and may be turned on again at any time by the user, by using the keyword list.

Optional parameter settings are preserved following a call to E04DGF, and so the keyword defaults is provided to allow the user to reset all the optional parameters to their default values by the statement,

```
CALL E04DKF ('Defaults')
```

prior to a subsequent call to E04DGF.

A complete list of optional parameters, their abbreviations, synonyms and default values is given in Section 5.1 of the routine document for E04DGF.

4. References

None.

5. Parameters

- 1: STRING -- CHARACTER*(*) Input
On entry: STRING must be a single valid option string. See Section 3 above, and Section 5.1 of the routine document for E04DGF.

6. Error Indicators and Warnings

If the parameter STRING is not recognised as a valid option string, then a warning message is output on the current advisory message unit (see X04ABF).

7. Accuracy

Not applicable.

8. Further Comments

E04DJF may also be used to supply optional parameters to E04DGF.

9. Example

See the example for E04DGF.

%%%

E04 -- Minimizing or Maximizing a Function E04FDF
 E04FDF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E04FDF is an easy-to-use algorithm for finding an unconstrained minimum of a sum of squares of m nonlinear functions in n variables ($m \geq n$). No derivatives are required.

It is intended for functions which are continuous and which have continuous first and second derivatives (although it will usually work even if the derivatives have occasional discontinuities).

2. Specification

```
SUBROUTINE E04FDF (M, N, X, FSUMSQ, IW, LIW, W, LW, IFAIL)
  INTEGER          M, N, IW(LIW), LIW, LW, IFAIL
  DOUBLE PRECISION X(N), FSUMSQ, W(LW)
```

3. Description

This routine is essentially identical to the subroutine LSNDN1 in the National Physical Laboratory Algorithms Library. It is applicable to problems of the form

$$\text{Minimize } F(x) = \sum_{i=1}^m [f_i(x)]^2$$

where $x = (x_1, x_2, \dots, x_n)^T$ and $m \geq n$. (The functions $f_i(x)$ are often referred to as 'residuals'.) The user must supply a subroutine LSFUN1 to evaluate functions $f_i(x)$ at any point x .

From a starting point supplied by the user, a sequence of points

is generated which is intended to converge to a local minimum of the sum of squares. These points are generated using estimates of the curvature of $F(x)$.

4. References

- [1] Gill P E and Murray W (1978) Algorithms for the Solution of the Nonlinear Least-squares Problem. SIAM J. Numer. Anal. 15 977--992.

5. Parameters

- 1: M -- INTEGER Input
- 2: N -- INTEGER Input
 On entry: the number m of residuals $f_i(x)$, and the number n of variables, x_j . Constraint: $1 \leq N \leq M$.
- 3: X(N) -- DOUBLE PRECISION array Input/Output
 On entry: $X(j)$ must be set to a guess at the j th component of the position of the minimum, for $j=1,2,\dots,n$. On exit: the lowest point found during the calculations. Thus, if IFAIL = 0 on exit, $X(j)$ is the j th component of the position of the minimum.
- 4: FSUMSQ -- DOUBLE PRECISION Output
 On exit: the value of the sum of squares, $F(x)$, corresponding to the final point stored in X.
- 5: IW(LIW) -- INTEGER array Workspace
- 6: LIW -- INTEGER Input
 On entry: the length of IW as declared in the (sub)program from which E04FDF has been called. Constraint: $LIW \geq 1$.
- 7: W(LW) -- DOUBLE PRECISION array Workspace
- 8: LW -- INTEGER Input
 On entry: the length of W as declared in the (sub)program from which E04FDF is called. Constraints:
 $LW \geq N*(7 + N + 2*M + (N-1)/2) + 3*M$, if $N > 1$,
 $LW \geq 9 + 5*M$, if $N = 1$.

9: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL \neq 0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

5.1. Optional Parameters

LSFUN1 -- SUBROUTINE, supplied by the user.

External Procedure

This routine must be supplied by the user to calculate the vector of values $f(x)$ at any point x . Since the routine is

i

not a parameter to E04FDF, it must be called LSFUN1. It should be tested separately before being used in conjunction with E04FDF (see the Chapter Introduction).

Its specification is:

```
SUBROUTINE LSFUN1 (M, N, XC, FVECC)
  INTEGER          M, N
  DOUBLE PRECISION XC(N), FVECC(M)
```

1: M -- INTEGER Input

2: N -- INTEGER Input
 On entry: the numbers m and n of residuals and variables, respectively.

3: XC(N) -- DOUBLE PRECISION array Input
 On entry: the point x at which the values of the f
 i
 are required.

4: FVECC(M) -- DOUBLE PRECISION array Output
 On exit: FVECC(i) must contain the value of f at the
 i
 point x , for $i=1,2,\dots,m$.

LSFUN1 must be declared as EXTERNAL in the (sub)program

from which E04FDF is called. Parameters denoted as Input must not be changed by this procedure.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry $N < 1$,

or $M < N$,

or $LIW < 1$,

or $LW < N*(7 + N + 2*M + (N-1)/2) + 3*M$, when $N > 1$,

or $LW < 9 + 5*M$, when $N = 1$.

IFAIL= 2

There have been $400*n$ calls of LSFUN1, yet the algorithm does not seem to have converged. This may be due to an awkward function or to a poor starting point, so it is worth restarting E04FDF from the final point held in X.

IFAIL= 3

The final point does not satisfy the conditions for acceptance as a minimum, but no lower point could be found.

IFAIL= 4

An auxiliary routine has been unable to complete a singular value decomposition in a reasonable number of sub-iterations.

IFAIL= 5

IFAIL= 6

IFAIL= 7

IFAIL= 8

There is some doubt about whether the point x found by E04FDF is a minimum of $F(x)$. The degree of confidence in the result decreases as IFAIL increases. Thus when IFAIL = 5, it

is probable that the final x gives a good estimate of the position of a minimum, but when $IFAIL = 8$ it is very unlikely that the routine has found a minimum.

If the user is not satisfied with the result (e.g. because $IFAIL$ lies between 3 and 8), it is worth restarting the calculations from a different starting point (not the point at which the failure occurred) in order to avoid the region which caused the failure. Repeated failure may indicate some defect in the formulation of the problem.

7. Accuracy

If the problem is reasonably well scaled and a successful exit is made, then, for a computer with a mantissa of t decimals, one would expect to get about $t/2-1$ decimals accuracy in the components of x and between $t-1$ (if $F(x)$ is of order 1 at the minimum) and $2t-2$ (if $F(x)$ is close to zero at the minimum) decimals accuracy in $F(x)$.

8. Further Comments

The number of iterations required depends on the number of variables, the number of residuals and their behaviour, and the distance of the starting point from the solution. The number of multiplications performed per iteration of E04FDF varies, but for

$m \gg n$ is approximately $n^2 m + O(n^3)$. In addition, each iteration makes at least $n+1$ calls of LSFUN1. So, unless the residuals can be evaluated very quickly, the run time will be dominated by the time spent in LSFUN1.

Ideally, the problem should be scaled so that the minimum value of the sum of squares is in the range $(0,1)$, and so that at points a unit distance away from the solution the sum of squares is approximately a unit value greater than at the minimum. It is unlikely that the user will be able to follow these recommendations very closely, but it is worth trying (by guesswork), as sensible scaling will reduce the difficulty of the minimization problem, so that E04FDF will take less computer time.

When the sum of squares represents the goodness of fit of a nonlinear model to observed data, elements of the variance-covariance matrix of the estimated regression coefficients can be computed by a subsequent call to E04YCF, using information

returned in segments of the workspace array W. See E04YCF for further details.

9. Example

To find least-squares estimates of x_1 , x_2 and x_3 in the model

$$y = x_1 + \frac{t_1}{x_2^2 + x_3^2}$$

using the 15 sets of data given in the following table.

y	t ₁	t ₂	t ₃
0.14	1.0	15.0	1.0
0.18	2.0	14.0	2.0
0.22	3.0	13.0	3.0
0.25	4.0	12.0	4.0
0.29	5.0	11.0	5.0
0.32	6.0	10.0	6.0
0.35	7.0	9.0	7.0
0.39	8.0	8.0	8.0
0.37	9.0	7.0	7.0
0.58	10.0	6.0	6.0
0.73	11.0	5.0	5.0
0.96	12.0	4.0	4.0
1.34	13.0	3.0	3.0
2.10	14.0	2.0	2.0
4.39	15.0	1.0	1.0

The program uses (0.5, 1.0, 1.5) as the initial guess at the position of the minimum.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E04 -- Minimizing or Maximizing a Function

E04GCF

E04GCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E04GCF is an easy-to-use quasi-Newton algorithm for finding an unconstrained minimum of a sum of squares of m nonlinear functions in n variables ($m \geq n$). First derivatives are required.

It is intended for functions which are continuous and which have continuous first and second derivatives (although it will usually work even if the derivatives have occasional discontinuities).

2. Specification

```
SUBROUTINE E04GCF (M, N, X, FSUMSQ, IW, LIW, W, LW, IFAIL)
  INTEGER          M, N, IW(LIW), LIW, LW, IFAIL
  DOUBLE PRECISION X(N), FSUMSQ, W(LW)
```

3. Description

This routine is essentially identical to the subroutine LSFQ2 in the National Physical Laboratory Algorithms Library. It is applicable to problems of the form

$$\text{Minimize } F(x) = \sum_{i=1}^m [f_i(x)]^2$$

where $x = (x_1, x_2, \dots, x_n)^T$ and $m \geq n$. (The functions $f_i(x)$ are often referred to as 'residuals'.) The user must supply a subroutine LSFUN2 to evaluate the residuals and their first derivatives at any point x .

Before attempting to minimize the sum of squares, the algorithm checks LSFUN2 for consistency. Then, from a starting point supplied by the user, a sequence of points is generated which is intended to converge to a local minimum of the sum of squares. These points are generated using estimates of the curvature of $F(x)$.

4. References

- [1] Gill P E and Murray W (1978) Algorithms for the Solution of the Nonlinear Least-squares Problem. SIAM J. Numer. Anal. 15 977--992.

5. Parameters

- 1: M -- INTEGER Input
- 2: N -- INTEGER Input
 On entry: the number m of residuals $f(x)$, and the number n of variables, x_j . Constraint: $1 \leq N \leq M$.
- 3: X(N) -- DOUBLE PRECISION array Input/Output
 On entry: X(j) must be set to a guess at the j th component of the position of the minimum, for $j=1,2,\dots,n$. The routine checks the first derivatives calculated by LSFUN2 at the starting point, and so is more likely to detect an error in the user's routine if the initial X(j) are non-zero and mutually distinct. On exit: the lowest point found during the calculations. Thus, if IFAIL = 0 on exit, X(j) is the j th component of the position of the minimum.
- 4: FSUMSQ -- DOUBLE PRECISION Output
 On exit: the value of the sum of squares, F(x), corresponding to the final point stored in X.
- 5: IW(LIW) -- INTEGER array Workspace
- 6: LIW -- INTEGER Input
 On entry: the length of IW as declared in the (sub)program from which E04GCF is called. Constraint: LIW \geq 1.
- 7: W(LW) -- DOUBLE PRECISION array Workspace
- 8: LW -- INTEGER Input
 On entry: the length of W as declared in the (sub)program from which E04GCF is called. Constraints:
 $LW \geq 2*N*(4 + N + M) + 3*M$, if $N > 1$,
 $LW \geq 11 + 5*M$, if $N = 1$.

9: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL \neq 0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

5.1. Optional Parameters

LSFUN2 -- SUBROUTINE, supplied by the user.

External Procedure

This routine must be supplied by the user to calculate the vector of values $f(x)$ and the Jacobian matrix of first

i

ddf

i

derivatives ---- at any point x . Since the routine is not a

ddx

j

parameter to E04GCF, it must be called LSFUN2. It should be tested separately before being used in conjunction with E04GCF (see the Chapter Introduction).

Its specification is:

SUBROUTINE LSFUN2 (M, N, XC, FVECC, FJACC, LJC)

INTEGER M, N, LJC

DOUBLE PRECISION XC(N), FVECC(M), FJACC(LJC,N)

Important: The dimension declaration for FJACC must contain the variable LJC, not an integer constant.

1: M -- INTEGER Input

2: N -- INTEGER Input

On entry: the numbers m and n of residuals and variables, respectively.

3: XC(N) -- DOUBLE PRECISION array Input

On entry: the point x at which the values of the f

i

ddf
 i
 and the ---- are required.
 ddx
 j

4: FVECC(M) -- DOUBLE PRECISION array Output
 On exit: FVECC(i) must contain the value of f at the
 i
 point x, for i=1,2,...,m.

5: FJACC(LJC,N) -- DOUBLE PRECISION array Output
 ddf
 i
 On exit: FJACC(i,j) must contain the value of ---- at
 ddx
 j
 the point x, for i=1,2,...,m; j=1,2,...,n.

6: LJC -- INTEGER Input
 On entry: the first dimension of the array FJACC.
 LSFUN2 must be declared as EXTERNAL in the (sub)program
 from which E04GCF is called. Parameters denoted as
 Input must not be changed by this procedure.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are
 output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry N < 1,

or M < N,

or LIW < 1,

or LW < 2*N*(4 + N + M) + 3*M, when N > 1,

or LW < 9 + 5*M, when N = 1.

IFAIL= 2

There have been 50*n calls of LSFUN2, yet the algorithm does
 not seem to have converged. This may be due to an awkward

function or to a poor starting point, so it is worth restarting E04GCF from the final point held in X.

IFAIL= 3

The final point does not satisfy the conditions for acceptance as a minimum, but no lower point could be found.

IFAIL= 4

An auxiliary routine has been unable to complete a singular value decomposition in a reasonable number of sub-iterations.

IFAIL= 5

IFAIL= 6

IFAIL= 7

IFAIL= 8

There is some doubt about whether the point X found by E04GCF is a minimum of $F(x)$. The degree of confidence in the result decreases as IFAIL increases. Thus, when IFAIL = 5, it is probable that the final x gives a good estimate of the position of a minimum, but when IFAIL = 8 it is very unlikely that the routine has found a minimum.

IFAIL= 9

It is very likely that the user has made an error in forming

$$\begin{array}{c} \text{ddf} \\ i \\ \text{the derivatives} \quad \text{----} \text{ in LSFUN2.} \\ \text{ddx} \\ j \end{array}$$

If the user is not satisfied with the result (e.g. because IFAIL lies between 3 and 8), it is worth restarting the calculations from a different starting point (not the point at which the failure occurred) in order to avoid the region which caused the failure. Repeated failure may indicate some defect in the formulation of the problem.

7. Accuracy

If the problem is reasonably well scaled and a successful exit is made then, for a computer with a mantissa of t decimals, one would expect to get $t/2-1$ decimals accuracy in the components of

x and between $t-1$ (if $F(x)$ is of order 1 at the minimum) and $2t-2$ (if $F(x)$ is close to zero at the minimum) decimals accuracy in $F(x)$.

8. Further Comments

The number of iterations required depends on the number of variables, the number of residuals and their behaviour, and the distance of the starting point from the solution. The number of multiplications performed per iteration of E04GCF varies, but for

$m \gg n$ is approximately $n^2 m + O(n^3)$. In addition, each iteration makes at least one call of LSFUN2. So, unless the residuals and their derivatives can be evaluated very quickly, the run time will be dominated by the time spent in LSFUN2.

Ideally the problem should be scaled so that the minimum value of the sum of squares is in the range (0,1) and so that at points a unit distance away from the solution the sum of squares is approximately a unit value greater than at the minimum. It is unlikely that the user will be able to follow these recommendations very closely, but it is worth trying (by guesswork), as sensible scaling will reduce the difficulty of the minimization problem, so that E04GCF will take less computer time.

When the sum of squares represents the goodness of fit of a nonlinear model to observed data, elements of the variance-covariance matrix of the estimated regression coefficients can be computed by a subsequent call to E04YCF, using information returned in segments of the workspace array W. See E04YCF for further details.

9. Example

To find the least-squares estimates of x_1 , x_2 and x_3 in the model

$$y = x_1 + \frac{t}{x_2^2 + x_3^2}$$

using the 15 sets of data given in the following table.

y	t	t	t
	1	2	3
0.14	1.0	15.0	1.0
0.18	2.0	14.0	2.0
0.22	3.0	13.0	3.0
0.25	4.0	12.0	4.0
0.29	5.0	11.0	5.0
0.32	6.0	10.0	6.0
0.35	7.0	9.0	7.0
0.39	8.0	8.0	8.0
0.37	9.0	7.0	7.0
0.58	10.0	6.0	6.0
0.73	11.0	5.0	5.0
0.96	12.0	4.0	4.0
1.34	13.0	3.0	3.0
2.10	14.0	2.0	2.0
4.39	15.0	1.0	1.0

The program uses (0.5, 1.0, 1.5) as the initial guess at the position of the minimum.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E04 -- Minimizing or Maximizing a Function

E04JAF

E04JAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E04JAF is an easy-to-use quasi-Newton algorithm for finding a minimum of a function $F(x_1, x_2, \dots, x_n)$, subject to fixed upper and lower bounds of the independent variables x_1, x_2, \dots, x_n , using function values only.

It is intended for functions which are continuous and which have continuous first and second derivatives (although it will usually

work even if the derivatives have occasional discontinuities).

2. Specification

```

SUBROUTINE E04JAF (N, IBOUND, BL, BU, X, F, IW, LIW, W,
1                LW, IFAIL)
INTEGER          N, IBOUND, IW(LIW), LIW, LW, IFAIL
DOUBLE PRECISION BL(N), BU(N), X(N), F, W(LW)

```

3. Description

This routine is applicable to problems of the form:

$$\text{Minimize } F(x_1, x_2, \dots, x_n) \text{ subject to } l_j \leq x_j \leq u_j, \quad j=1, 2, \dots, n$$

when derivatives of $F(x)$ are unavailable.

Special provision is made for problems which actually have no bounds on the x_j , problems which have only non-negativity bounds

and problems in which $l_1 = l_2 = \dots = l_n$ and $u_1 = u_2 = \dots = u_n$. The user

must supply a subroutine FUNCT1 to calculate the value of $F(x)$ at any point x .

From a starting point supplied by the user there is generated, on the basis of estimates of the gradient and the curvature of $F(x)$, a sequence of feasible points which is intended to converge to a local minimum of the constrained function. An attempt is made to verify that the final point is a minimum.

4. References

- [1] Gill P E and Murray W (1976) Minimization subject to bounds on the variables. Report NAC 72. National Physical Laboratory.

5. Parameters

- 1: N -- INTEGER Input
 On entry: the number n of independent variables.
 Constraint: $N \geq 1$.
- 2: IBOUND -- INTEGER Input
 On entry: indicates whether the facility for dealing with

bounds of special forms is to be used.

It must be set to one of the following values:

IBOUND = 0

if the user will be supplying all the l_j and u_j individually.

IBOUND = 1

if there are no bounds on any x_j .

IBOUND = 2

if all the bounds are of the form $0 \leq x_j$.

IBOUND = 3

if $l_1 = l_2 = \dots = l_n$ and $u_1 = u_2 = \dots = u_n$.

- 3: BL(N) -- DOUBLE PRECISION array Input/Output
 On entry: the lower bounds l_j .

If IBOUND is set to 0, the user must set $BL(j)$ to l_j , for $j=1,2,\dots,n$. (If a lower bound is not specified for a particular x_j , the corresponding $BL(j)$ should be set to $-10.$)⁶

If IBOUND is set to 3, the user must set $BL(1)$ to l_1 ; E04JAF¹ will then set the remaining elements of BL equal to $BL(1)$.
 On exit: the lower bounds actually used by E04JAF.

- 4: BU(N) -- DOUBLE PRECISION array Input/Output
 On entry: the upper bounds u_j .

If IBOUND is set to 0, the user must set $BU(j)$ to u_j , for $j=1,2,\dots,n$. (If an upper bound is not specified for a particular x_j , the corresponding $BU(j)$ should be set to $10.$)⁶

If IBOUND is set to 3, the user must set BU(1) to u ; E04JAF₁
 will then set the remaining elements of BU equal to BU(1).
 On exit: the upper bounds actually used by E04JAF.

- 5: X(N) -- DOUBLE PRECISION array Input/Output
 On entry: X(j) must be set to an estimate of the jth
 component of the position of the minimum, for j=1,2,...,n.
 On exit: the lowest point found during the calculations.
 Thus, if IFAIL = 0 on exit, X(j) is the jth component of the
 position of the minimum.
- 6: F -- DOUBLE PRECISION Output
 On exit: the value of F(x) corresponding to the final point
 stored in X.
- 7: IW(LIW) -- INTEGER array Workspace
- 8: LIW -- INTEGER Input
 On entry: the length of IW as declared in the (sub)program
 from which E04JAF is called. Constraint: LIW >= N + 2.
- 9: W(LW) -- DOUBLE PRECISION array Workspace
- 10: LW -- INTEGER Input
 On entry: the length of W as declared in the (sub)program
 from which E04JAF is called. Constraint: LW >= max(N*(N-
 1)/2+12*N,13).
- 11: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. Users who are
 unfamiliar with this parameter should refer to the Essential
 Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or
 gives a warning (see Section 6).

For this routine, because the values of output parameters
 may be useful even if IFAIL /=0 on exit, users are
 recommended to set IFAIL to -1 before entry. It is then
 essential to test the value of IFAIL on exit. To suppress
 the output of an error message when soft failure occurs, set
 IFAIL to 1.

5.1. Optional Parameters

FUNCT1 -- SUBROUTINE, supplied by the user.

External Procedure

This routine must be supplied by the user to calculate the value of the function $F(x)$ at any point x . Since this routine is not a parameter to E04JAF, it must be called FUNCT1. It should be tested separately before being used in conjunction with E04JAF (see the Chapter Introduction).

Its specification is:

```
SUBROUTINE FUNCT1 (N, XC, FC)
      INTEGER          N
      DOUBLE PRECISION XC(N), FC
```

- | | |
|---|--------|
| 1: N -- INTEGER | Input |
| On entry: the number n of variables. | |
| | |
| 2: XC(N) -- DOUBLE PRECISION array | Input |
| On entry: the point x at which the function value is required. | |
| | |
| 3: FC -- DOUBLE PRECISION | Output |
| On exit: the value of the function F at the current point x . | |

FUNCT1 must be declared as EXTERNAL in the (sub)program from which E04JAF is called. Parameters denoted as Input must not be changed by this procedure.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

IFAIL= 1

On entry $N < 1$,

or IBOUND < 0 ,

or IBOUND > 3 ,

or IBOUND = 0 and $BL(j) > BU(j)$ for some j ,

or IBOUND = 3 and $BL(1) > BU(1)$,

or LIW $< N + 2$,

or $LW < \max(13, 12 \cdot N + N \cdot (N-1)/2)$.

IFAIL= 2

There have been $400 \cdot n$ function evaluations, yet the algorithm does not seem to be converging. The calculations can be restarted from the final point held in X. The error may also indicate that F(x) has no minimum.

IFAIL= 3

The conditions for a minimum have not all been met but a lower point could not be found and the algorithm has failed.

IFAIL= 4

An overflow has occurred during the computation. This is an unlikely failure, but if it occurs the user should restart at the latest point given in X.

IFAIL= 5

IFAIL= 6

IFAIL= 7

IFAIL= 8

There is some doubt about whether the point x found by E04JAF is a minimum. The degree of confidence in the result decreases as IFAIL increases. Thus, when IFAIL = 5 it is probable that the final x gives a good estimate of the position of a minimum, but when IFAIL = 8 it is very unlikely that the routine has found a minimum.

IFAIL= 9

In the search for a minimum, the modulus of one of the
 6
 variables has become very large ($\sim 10^6$). This indicates that there is a mistake in FUNCT1, that the user's problem has no finite solution, or that the problem needs rescaling (see Section 8).

If the user is dissatisfied with the result (e.g. because IFAIL = 5, 6, 7 or 8), it is worth restarting the calculations from a different starting point (not the point at which the failure occurred) in order to avoid the region which caused the failure. If persistent trouble occurs and the gradient can be calculated, it may be advisable to change to a routine which uses gradients (see the Chapter Introduction).

7. Accuracy

When a successful exit is made then, for a computer with a mantissa of t decimals, one would expect to get about $t/2-1$ decimals accuracy in x and about $t-1$ decimals accuracy in F , provided the problem is reasonably well scaled.

8. Further Comments

The number of iterations required depends on the number of variables, the behaviour of $F(x)$ and the distance of the starting point from the solution. The number of operations performed in an

iteration of E04JAF is roughly proportional to n^2 . In addition, each iteration makes at least $m+1$ calls of FUNCT1, where m is the number of variables not fixed on bounds. So, unless $F(x)$ can be evaluated very quickly, the run time will be dominated by the time spent in FUNCT1.

Ideally the problem should be scaled so that at the solution the value of $F(x)$ and the corresponding values of x_1, x_2, \dots, x_n are each in the range $(-1, +1)$, and so that at points a unit distance away from the solution, F is approximately a unit value greater than at the minimum. It is unlikely that the user will be able to follow these recommendations very closely, but it is worth trying (by guesswork), as sensible scaling will reduce the difficulty of the minimization problem, so that E04JAF will take less computer time.

9. Example

To minimize

$$F = (x_1^2 + 10x_2^2) + 5(x_3^2 - x_4^2) + (x_2^4 - 2x_3^4) + 10(x_1^4 - x_4^4)$$

subject to

$$1 \leq x_1 \leq 3$$

$$-2 \leq x_2 \leq 0$$

$$1 \leq x \leq 3,$$

$$4$$

starting from the initial guess (3, - 1, 0, 1).

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E04 -- Minimizing or Maximizing a Function E04MBF
 E04MBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E04MBF is an easy-to-use routine for solving linear programming problems, or for finding a feasible point for such problems. It is not intended for large sparse problems.

2. Specification

```

SUBROUTINE E04MBF (ITMAX, MSGVLV, N, NCLIN, NCTOTL, NROWA,
1                A, BL, BU, CVEC, LINOBJ, X, ISTATE,
2                OBJLP, CLAMDA, IWORK, LIWORK, WORK,
3                LWORK, IFAIL)
  INTEGER        ITMAX, MSGVLV, N, NCLIN, NCTOTL, NROWA,
1                ISTATE(NCTOTL), IWORK(LIWORK), LIWORK,
2                LWORK, IFAIL
  DOUBLE PRECISION A(NROWA,N), BL(NCTOTL), BU(NCTOTL), CVEC
1                (N), X(N), OBJLP, CLAMDA(NCTOTL), WORK
2                (LWORK)
  LOGICAL        LINOBJ

```

3. Description

E04MBF solves linear programming (LP) problems of the form

$$\begin{array}{ll} \text{Minimize} & c^T x \\ \text{subject to} & l \leq (Ax) \leq u \end{array} \quad (LP)$$

$$x \text{ is in } R^n$$

where c is an n element vector and A is an m by n matrix i.e., there are n variables and m general linear constraints. m may be zero in which case the LP problem is subject only to bounds on the variables. Notice that upper and lower bounds are specified for all the variables and constraints. This form allows full generality in specifying other types of constraints. For example the i th constraint may be specified as equality by setting $l_i = u_i$. If certain bounds are not present the associated elements of l or u can be set to special values that will be treated as $-\infty$ or $+\infty$.

The routine allows the linear objective function to be omitted in which case a feasible point for the set of constraints is sought.

The user must supply an initial estimate of the solution.

Users who wish to exercise additional control and users with problems whose solution would benefit from additional flexibility should consider using the comprehensive routine EO4NAF.

5. Parameters

- 1: ITMAX -- INTEGER Input
On entry: an upper bound on the number of iterations to be taken. If ITMAX is not positive, then the value 50 is used in place of ITMAX.
- 2: MSGLVL -- INTEGER Input
On entry: indicates whether or not printout is required at the final solution. When printing occurs the output is on the advisory message channel (see X04ABF). A description of the printed output is given in Section 5.1. The level of printing is determined as follows:

MSGLVL < 0

No printing.

MSGLVL = 0

Printing only if an input parameter is incorrect, or if the problem is so ill-conditioned that subsequent overflow is likely. This setting is strongly recommended in preference to MSGLVL < 0.

MSGLVL = 1

Printing at the solution.

MSGLVL > 1

Values greater than 1 should normally be used only at the direction of NAG; such values may generate large amounts of printed output.

- 3: N -- INTEGER Input
On entry: the number n of variables. Constraint: N >= 1.
- 4: NCLIN -- INTEGER Input
On entry: the number of general linear constraints in the problem. Constraint: NCLIN >= 0.
- 5: NCTOTL -- INTEGER Input
On entry: the value (N+NCLIN).
- 6: NROWA -- INTEGER Input
On entry:
the first dimension of the array A as declared in the (sub)program from which E04MBF is called.
Constraint: NROWA >= max(1,NCLIN).
- 7: A(NROWA,N) -- DOUBLE PRECISION array Input
On entry: the leading NCLIN by n part of A must contain the NCLIN general constraints, with the coefficients of the ith constraint in the ith row of A. If NCLIN = 0, then A is not referenced.
- 8: BL(NCTOTL) -- DOUBLE PRECISION array Input
On entry: the first n elements of BL must contain the lower bounds on the n variables, and when NCLIN > 0, the next NCLIN elements of BL must contain the lower bounds on the NCLIN general linear constraints. To specify a non-existent lower bound (1 == -infty), set BL(j) <= -1.0E+20.

j

9: BU(NCTOTL) -- DOUBLE PRECISION array Input
 On entry: the first n elements of BU must contain the upper bounds on the n variables, and when $NCLIN > 0$, the next $NCLIN$ elements of BU must contain the upper bounds on the $NCLIN$ general linear constraints. To specify a non-existent upper bound ($u = +\infty$), set $BU(j) \geq 1.0E+20$. Constraint:

$$BL(j) \leq BU(j), \text{ for } j=1,2,\dots,NCTOTL.$$

10: CVEC(N) -- DOUBLE PRECISION array Input
 On entry: with $LINOBJ = .TRUE.$, CVEC must contain the coefficients of the objective function. If $LINOBJ = .FALSE.$, then CVEC is not referenced.

11: LINOBJ -- LOGICAL Input
 On entry: indicates whether or not a linear objective function is present. If $LINOBJ = .TRUE.$, then the full LP problem is solved, but if $LINOBJ = .FALSE.$, only a feasible point is found and the array CVEC is not referenced.

12: X(N) -- DOUBLE PRECISION array Input/Output
 On entry: an estimate of the solution, or of a feasible point. Even when $LINOBJ = .TRUE.$ it is not necessary for the point supplied in X to be feasible. In the absence of better information all elements of X may be set to zero. On exit: the solution to the LP problem when $LINOBJ = .TRUE.$, or a feasible point when $LINOBJ = .FALSE.$.

When no feasible point exists (see $IFAIL = 1$ in Section 6) then X contains the point for which the sum of the infeasibilities is a minimum. On return with $IFAIL = 2, 3$ or 4 , X contains the point at which EO4MBF terminated.

13: ISTATE(NCTOTL) -- INTEGER array Output
 On exit: with $IFAIL < 5$, ISTATE indicates the status of every constraint at the final point. The first n elements of ISTATE refer to the upper and lower bounds on the variables and when $NCLIN > 0$ the next $NCLIN$ elements refer to the general constraints.

Their meaning is:

ISTATE(j) Meaning

-2 The constraint violates its lower bound. This value cannot occur for any element of ISTATE when

a feasible point has been found.

- 1 The constraint violates its upper bound. This value cannot occur for any element of ISTATE when a feasible point has been found.
- 0 The constraint is not in the working set (is not active) at the final point. Usually this means that the constraint lies strictly between its bounds.
- 1 This inequality constraint is in the working set (is active) at its lower bound.
- 2 This inequality constraint is in the working set (is active) at its upper bound.
- 3 This constraint is included in the working set (is active) as an equality. This value can only occur when $BL(j) = BU(j)$.

14: OBJLP -- DOUBLE PRECISION Output
 On exit: when LINOBJ = .TRUE., then on successful exit, OBJLP contains the value of the objective function at the solution, and on exit with IFAIL = 2, 3 or 4, OBJLP contains the value of the objective function at the point returned in X.

When LINOBJ = .FALSE., then on successful exit OBJLP will be zero and on return with IFAIL = 1, OBJLP contains the minimum sum of the infeasibilities corresponding to the point returned in X.

15: CLAMDA(NCTOTL) -- DOUBLE PRECISION array Output
 On exit: when LINOBJ = .TRUE., then on successful exit, or on exit with IFAIL = 2, 3, or 4, CLAMDA contains the Lagrange multipliers (reduced costs) for each constraint with respect to the working set. The first n components of CLAMDA contain the multipliers for the bound constraints on the variables and the remaining NCLIN components contain the multipliers for the general linear constraints.

If ISTATE(j) = 0 so that the jth constraint is not in the working set then CLAMDA(j) is zero. If X is optimal and ISTATE(j) = 1, then CLAMDA(j) should be non-negative, and if ISTATE(j) = 2, then CLAMDA(j) should be non-positive.

```

16:  IWORK(LIWORK) -- INTEGER array                               Workspace

17:  LIWORK -- INTEGER                                           Input
    On entry: the length of the array IWORK as declared in the
    (sub)program from which EO4MBF is called. Constraint:
    LIWORK>=2*N.

18:  WORK(LWORK) -- DOUBLE PRECISION array                       Workspace

19:  LWORK -- INTEGER                                           Input
    On entry: the length of the array WORK as declared in the
    (sub)program from which EO4MBF is called. Constraints:
    when N <= NCLIN then
        2
        LWORK>=2*N +6*N+4*NCLIN+NROWA;

    when 0 <= NCLIN < N then
        2
        LWORK>=2*(NCLIN+1) +4*NCLIN+6*N+NROWA.

20:  IFAIL -- INTEGER                                           Input/Output
    On entry: IFAIL must be set to 0, -1 or 1. Users who are
    unfamiliar with this parameter should refer to the Essential
    Introduction for details.

    On exit: IFAIL = 0 unless the routine detects an error or
    gives a warning (see Section 6).

    For this routine, because the values of output parameters
    may be useful even if IFAIL /=0 on exit, users are
    recommended to set IFAIL to -1 before entry. It is then
    essential to test the value of IFAIL on exit. To suppress
    the output of an error message when soft failure occurs, set
    IFAIL to 1.

```

When MSGLVL = 1, then E04MBF will produce output on the advisory message channel (see X04ABF), giving information on the final point. The following describes the printout associated with each variable.

Output	Meaning
VARBL	The name (V) and index j, for $j=1,2,\dots,n$, of the variable.
STATE	The state of the variable. (FR if neither bound is in the working set, EQ for a fixed variable, LL if on its lower bound, UL if on its upper bound and TB if held on a temporary bound.) If the value of the variable lies outside the upper or lower bound then STATE will be ++ or -- respectively.
VALUE	The value of the variable at the final iteration.
LOWER BOUND	The lower bound specified for the variable.
UPPER BOUND	The upper bound specified for the variable.
LAGR MULT	The value of the Lagrange multiplier for the associated bound.
RESIDUAL	The difference between the value of the variable and the nearer of its bounds.

For each of the general constraints the printout is as above with refers to the jth element of Ax, except that VARBL is replaced by:

LNCON	The name (L) and index j, for $j = 1,2,\dots,NCLIN$ of the constraint.
-------	--

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

Note: when MSGVL=1 a short description of the error is printed.

IFAIL= 1

No feasible point could be found. Moving violated constraints so that they are satisfied at the point returned in X gives the minimum moves necessary to make the LP problem feasible.

IFAIL= 2

The solution to the LP problem is unbounded.

IFAIL= 3

A total of 50 changes were made to the working set without altering x . Cycling is probably occurring. The user should consider using EO4NAF with MSGLVL ≥ 5 to monitor constraint additions and deletions in order to determine whether or not cycling is taking place.

IFAIL= 4

The limit on the number of iterations has been reached. Increase ITMAX or consider using EO4NAF to monitor progress.

IFAIL= 5

An input parameter is invalid. Unless MSGLVL < 0 a message will be printed.

IFAILOverflow

If the printed output before the overflow occurred contains a warning about serious ill-conditioning in the working set when adding the j th constraint, then either the user should try using EO4NAF and experiment with the magnitude of FEATOL(j) in that routine, or the offending linearly dependent constraint (with index j) should be removed from the problem.

7. Accuracy

The routine implements a numerically stable active set strategy and returns solutions that are as accurate as the condition of the LP problem warrants on the machine.

8. Further Comments

The time taken by each iteration is approximately proportional to $\min(n^2, NCLIN^2)$.

Sensible scaling of the problem is likely to reduce the number of iterations required and make the problem less sensitive to perturbations in the data, thus improving the condition of the LP problem. In the absence of better information it is usually sensible to make the Euclidean lengths of each constraint of comparable magnitude. See Gill et al [1] for further information and advice.

Note that the routine allows constraints to be violated by an absolute tolerance equal to the machine precision (see X02AJF(*))

9. Example

To minimize the function

$$\begin{array}{ccccccc} -0.02x & -0.2x & -0.2x & -0.2x & -0.2x & +0.04x & +0.04x \\ 1 & 2 & 3 & 4 & 5 & 6 & 7 \end{array}$$

subject to the bounds

$$\begin{array}{l} -0.01 \leq x_1 \leq 0.01 \\ -0.1 \leq x_2 \leq 0.15, \\ -0.01 \leq x_3 \leq 0.03, \\ -0.04 \leq x_4 \leq 0.02, \\ -0.1 \leq x_5 \leq 0.05, \\ -0.01 \leq x_6 \\ -0.01 \leq x_7 \end{array}$$

and the general constraints

$$\begin{array}{ccccccc} x_1 & +x_2 & +x_3 & +x_4 & +x_5 & +x_6 & +x_7 = -0.13 \end{array}$$

$$\begin{array}{ccccccc} 0.15x_1 & +0.04x_2 & +0.02x_3 & +0.04x_4 & +0.02x_5 & +0.01x_6 & +0.03x_7 \leq -0.0049 \end{array}$$

$$\begin{array}{cccccc} 0.03x_1 & +0.05x_2 & +0.08x_3 & +0.02x_4 & +0.06x_5 & +0.01x_6 \leq -0.0064 \end{array}$$

$$\begin{array}{ccccc} 0.02x_1 & +0.04x_2 & +0.01x_3 & +0.02x_4 & +0.02x_5 \leq -0.0037 \end{array}$$

$$\begin{array}{ccc} 0.02x_1 & +0.03x_2 & +0.01x_5 \leq -0.0012 \end{array}$$

$$\begin{array}{cccccc} -0.0992 \leq & 0.70x_1 & +0.75x_2 & +0.80x_3 & +0.75x_4 & +0.80x_5 & +0.97x_6 \end{array}$$

$$-0.003 \leq 0.02x_1 + 0.06x_2 + 0.08x_3 + 0.12x_4 + 0.02x_5 + 0.01x_6 + 0.97x_7 \leq 0.002$$

1 2 3 4 5 6 7

The initial point, which is infeasible, is

$$\begin{matrix} & & & & & & T \\ x = (-0.01, -0.03, 0.0, -0.01, -0.1, 0.02, 0.01) & . \\ 0 \end{matrix}$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E04 -- Minimizing or Maximizing a Function E04NAF
E04NAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E04NAF is a comprehensive routine for solving quadratic programming (QP) or linear programming (LP) problems. It is not intended for large sparse problems.

2. Specification

```

SUBROUTINE E04NAF (ITMAX, MSGVLV, N, NCLIN, NCTOTL, NROWA,
1                NROWH, NCOLH, BIGBND, A, BL, BU, CVEC,
2                FEATOL, HESS, QPHESS, COLD, LP, ORTHOG,
3                X, ISTATE, ITER, OBJ, CLAMDA, IWORK,
4                LIWORK, WORK, LWORK, IFAIL)
  INTEGER        ITMAX, MSGVLV, N, NCLIN, NCTOTL, NROWA,
1                NROWH, NCOLH, ISTATE(NCTOTL), ITER, IWORK
2                (LIWORK), LIWORK, LWORK, IFAIL
  DOUBLE PRECISION BIGBND, A(NROWA,N), BL(NCTOTL),

2                (NROWH,NCOLH), X(N), OBJ, CLAMDA(NCTOTL),
3                WORK(LWORK)
  LOGICAL        COLD, LP, ORTHOG
  EXTERNAL       QPHESS

```

3. Description

E04NAF is essentially identical to the subroutine SOL/QPSOL described in Gill et al [1].

E04NAF is designed to solve the quadratic programming (QP) problem - the minimization of a quadratic function subject to a set of linear constraints on the variables. The problem is assumed to be stated in the following form:

$$\text{Minimize } \frac{1}{2} c^T x + \frac{1}{2} x^T H x \quad \text{subject to } l \leq (Ax) \leq u, \quad (1)$$

where c is a constant n -vector and H is a constant n by n symmetric matrix; note that H is the Hessian matrix (matrix of second partial derivatives) of the quadratic objective function. The matrix A is m by n , where m may be zero; A is treated as a dense matrix.

The constraints involving A will be called the general constraints. Note that upper and lower bounds are specified for all the variables and for all the general constraints. The form of (1) allows full generality in specifying other types of constraints. In particular, an equality constraint is specified by setting $l_i = u_i$. If certain bounds are not present, the associated elements of l or u can be set to special values that will be treated as $-\infty$ or $+\infty$.

The user must supply an initial estimate of the solution to (1), and a subroutine that computes the product Hx for any given vector x . If H is positive-definite or positive semi-definite, E04NAF will obtain a global minimum; otherwise, the solution obtained will be a local minimum (which may or may not be a global minimum). If H is defined as the zero matrix, E04NAF will solve the resulting linear programming (LP) problem; however, this can be accomplished more efficiently by setting a logical variable in the call of the routine (see the parameter LP in Section 5).

E04NAF allows the user to provide the indices of the constraints that are believed to be exactly satisfied at the solution. This facility, known as a warm start, can lead to significant savings in computational effort when solving a sequence of related problems.

The method has two distinct phases. In the first (the LP phase), an iterative procedure is carried out to determine a feasible point. In this context, feasibility is defined by a user-provided array FEATOL; the j th constraint is considered satisfied if its violation does not exceed FEATOL(j). The second phase (the QP phase) generates a sequence of feasible iterates in order to minimize the quadratic objective function. In both phases, a subset of the constraints - called the working set - is used to define the search direction at each iteration; typically, the working set includes constraints that are satisfied to within the corresponding tolerances in the FEATOL array.

We now briefly describe a typical iteration in the QP phase. Let x_k denote the estimate of the solution at the k th iteration; the next iterate is defined by

$$x_{k+1} = x_k + (\alpha)_k p_k$$

where p_k is an n -dimensional search direction and $(\alpha)_k$ is a scalar step length. Assume that the working (active) set contains t_k linearly independent constraints, and let C_k denote the matrix of coefficients of the bounds and general constraints in the current working set.

Let Z_k denote a matrix whose columns form a basis for the null space of C_k , so that $C_k Z_k = 0$. (Note that Z_k has $n - t_k$ columns, where $n = n - t_k$.) The vector $Z_k^T (c_k + H_k x_k)$ is called the projected gradient at x_k . If the projected gradient is zero at x_k (i.e., x_k is a constrained stationary point in the subspace defined by Z_k), Lagrange multipliers $(\lambda)_k$ are defined as the solution of the compatible overdetermined system

$$C_k^T (\lambda)_k = c_k + H_k x_k \quad (2)$$

The Lagrange multiplier (λ) corresponding to an inequality constraint in the working set is said to be optimal if $(\lambda) \leq 0$ when the associated constraint is at its upper bound, or if $(\lambda) \geq 0$ when the associated constraint is at its lower bound. If a multiplier is non-optimal, the objective function can be reduced by deleting the corresponding constraint (with index JDEL, see Section 5.1) from the working set.

If the projected gradient at x_k is non-zero, the search direction

p_k is defined as

$$p_k = Z_k p_z \quad (3)$$

where p_z is an n -vector. In effect, the constraints in the working set are treated as equalities, by constraining p_k to lie within the subspace of vectors orthogonal to the rows of C_k . This definition ensures that $C_k p_k = 0$, and hence the values of the constraints in the working set are not altered by any move along p_k .

The vector p_z is obtained by solving the equations

$$Z_k^T H Z_k p_z = -Z_k^T (c + H x_k) \quad (4)$$

(The matrix $Z_k^T H Z_k$ is called the projected Hessian matrix.) If the projected Hessian is positive-definite, the vector defined by (3) and (4) is the step to the minimum of the quadratic function in the subspace defined by Z_k .

If the projected Hessian is positive-definite and $x_k + p_k$ is

feasible, (α) will be taken as unity. In this case, the projected gradient at x_k will be zero (see NORM ZTG in Section 5.1), and Lagrange multipliers can be computed (see Gill et al [2]). Otherwise, (α) is set to the step to the 'nearest' constraint (with index JADD, see Section 5.1), which is added to the working set at the next iteration.

The matrix Z_k is obtained from the TQ factorization of C_k , in which C_k is represented as

$$C_k = Q_k \begin{pmatrix} 0 & T_k \end{pmatrix} \quad (5)$$

where T_k is reverse-triangular. It follows from (5) that Z_k may be taken as the first n columns of Q_k . If the projected Hessian Z_k is positive-definite, (3) is solved using the Cholesky factorization

$$Z_k^T H Z_k = R_k R_k^T$$

where R_k is upper triangular. These factorizations are updated as constraints enter or leave the working set (see Gill et al [2] for further details).

An important feature of E04NAF is the treatment of indefiniteness in the projected Hessian. If the projected Hessian is positive-definite, it may become indefinite only when a constraint is deleted from the working set. In this case, a temporary modification (of magnitude HESS MOD, see Section 5.1) is added to the last diagonal element of the Cholesky factor. Once a modification has occurred, no further constraints are deleted from the working set until enough constraints have been added so that the projected Hessian is again positive-definite. If equation (1) has a finite solution, a move along the direction obtained by solving (4) with the modified Cholesky factor must encounter a constraint that is not already in the working set.

In order to resolve indefiniteness in this way, we must ensure that the projected Hessian is positive-definite at the first iterate in the QP phase. Given the n by n projected Hessian, a step-wise Cholesky factorization is performed with symmetric interchanges (and corresponding rearrangement of the columns of Z), terminating if the next step would cause the matrix to become indefinite. This determines the largest possible positive-definite principal sub-matrix of the (permuted) projected Hessian. If n steps of the Cholesky factorization have been successfully completed, the relevant projected Hessian is an n by n positive-definite matrix $Z^T H Z$, where Z comprises the first n columns of Z . The quadratic function will subsequently be minimized within subspaces of reduced dimension until the full projected Hessian is positive-definite.

If a linear program is being solved and there are fewer general constraints than variables, the method moves from one vertex to another while minimizing the objective function. When necessary, an initial vertex is defined by temporarily fixing some of the variables at their initial values.

Several strategies are used to control ill-conditioning in the working set. One such strategy is associated with the FEATOL array. Allowing the j th constraint to be violated by as much as FEATOL(j) often provides a choice of constraints that could be added to the working set. When a choice exists, the decision is based on the conditioning of the working set. Negative steps are occasionally permitted, since x_k may violate the constraint to be added.

5. Parameters

- 1: ITMAX -- INTEGER Input
 On entry: an upper bound on the number of iterations to be taken during the LP phase or the QP phase. If ITMAX is not positive, then the value 50 is used in place of ITMAX.
- 2: MSGLVL -- INTEGER Input
 On entry: MSGLVL must indicate the amount of intermediate output desired (see Section 5.1 for a description of the printed output). All output is written to the current advisory message unit (see X04ABF). For MSGLVL ≥ 10 , each level includes the printout for all lower levels.
- | Value | Definition |
|-----------|---|
| <0 | No printing. |
| 0 | Printing only if an input parameter is incorrect, or if the working set is so ill-conditioned that subsequent overflow is likely. This setting is strongly recommended in preference to MSGLVL < 0. |
| 1 | The final solution only. |
| 5 | One brief line of output for each constraint addition or deletion (no printout of the final solution). |
| ≥ 10 | The final solution and one brief line of output for each constraint addition or deletion. |
| ≥ 15 | At each iteration, X, ISTATE, and the indices of the free variables (i.e., the variables not currently held on a bound). |
| ≥ 20 | At each iteration, the Lagrange multiplier estimates and the general constraint values. |
| ≥ 30 | At each iteration, the diagonal elements of the matrix T associated with the TQ factorization of the |

working set, and the diagonal elements of the
Cholesky factor R of the projected Hessian.

>=80 Debug printout.

99 The arrays CVEC and HESS.

- 3: N -- INTEGER Input
On entry: the number, n, of variables. Constraint: N >= 1.

- 4: NCLIN -- INTEGER Input
On entry: the number of general linear constraints in the
problem. Constraint: NCLIN >= 0.

- 5: NCTOTL -- INTEGER Input
On entry: the value (N+NCLIN).

- 6: NROWA -- INTEGER Input
On entry:
the first dimension of the array A as declared in the
(sub)program from which E04NAF is called.
Constraint: NROWA >= max(1,NCLIN).

- 7: NROWH -- INTEGER Input
On entry: the first dimension of the array HESS as declared
in the (sub)program from which E04NAF is called.
Constraint: NROWH >= 1.

- 8: NCOLH -- INTEGER Input
On entry: the column dimension of the array HESS as declared
in the (sub)program from which E04NAF is called.
Constraint: NCOLH >= 1.

- 9: BIGBND -- DOUBLE PRECISION Input
On entry: BIGBND must denote an 'infinite' component of l
and u. Any upper bound greater than or equal to BIGBND will
be regarded as plus infinity, and a lower bound less than or
equal to -BIGBND will be regarded as minus infinity.
Constraint: BIGBND > 0.0.

- 10: A(NROWA,N) -- DOUBLE PRECISION array Input
On entry: the leading NCLIN by n part of A must contain the
NCLIN general constraints, with the ith constraint in the i
th row of A. If NCLIN = 0, then A is not referenced.

- 11: BL(NCTOTL) -- DOUBLE PRECISION array Input

On entry: the lower bounds for all the constraints, in the following order. The first n elements of BL must contain the lower bounds on the variables. If $NCLIN > 0$, the next $NCLIN$ elements of BL must contain the lower bounds for the general linear constraints. To specify a non-existent lower bound (i.e., $l = -\infty$), the value used must satisfy $BL(j) < -$

j

BIGBND To specify the j th constraint as an equality, the user must set $BL(j) = BU(j)$. Constraint: $BL(j) \leq BU(j)$, $j=1,2,\dots,NCTOTL$.

- 12: BU(NCTOTL) -- DOUBLE PRECISION array Input

On entry: the upper bounds for all the constraints, in the following order. The first n elements of BU must contain the upper bounds on the variables. If $NCLIN > 0$, the next $NCLIN$ elements of BU must contain the upper bounds for the general linear constraints. To specify a non-existent upper bound (i.e., $u = +\infty$), the value used must satisfy $BU(j) \geq$

j

BIGBND. To specify the j th constraint as an equality, the user must set $BU(j) = BL(j)$. Constraint: $BU(j) \geq BL(j)$, $j=1,2,\dots,NCTOTL$.

- 13: CVEC(N) -- DOUBLE PRECISION array Input

On entry: the coefficients of the linear term of the objective function (the vector c in equation (1)).

- 14: FEATOL(NCTOTL) -- DOUBLE PRECISION array Input

On entry: a set of positive tolerances that define the maximum permissible absolute violation in each constraint in order for a point to be considered feasible, i.e., if the violation in constraint j is less than $FEATOL(j)$, the point is considered to be feasible with respect to the j th constraint. The ordering of the elements of FEATOL is the same as that described above for BL.

The elements of FEATOL should not be too small and a warning message will be printed on the current advisory message channel if any element of FEATOL is less than the machine precision (see X02AJF(*)). As the elements of FEATOL increase, the algorithm is less likely to encounter difficulties with ill-conditioning and degeneracy. However, larger values of $FEATOL(j)$ mean that constraint j could be violated by a significant amount. It is recommended that $FEATOL(j)$ be set to a value equal to the largest acceptable violation for constraint j . For example, if the data

defining the constraints are of order unity and are correct to about 6 decimal digits, it would be appropriate to choose

-6

FEATOL(j) as 10^{-6} for all relevant j. Often the square root of the machine precision is a reasonable choice if the constraint is well scaled.

- 15: HESS(NROWH,NCOLH) -- DOUBLE PRECISION array Input
 On entry: HESS may be used to store the Hessian matrix H of equation (1) if desired. HESS is accessed only by the subroutine QPHESS and is not accessed if LP = .TRUE.. Refer to the specification of QPHESS (below) for further details of how HESS may be used to pass data to QPHESS.

- 16: QPHESS -- SUBROUTINE, supplied by the user.

External Procedure

QPHESS must define the product of the Hessian matrix H and a vector x. The elements of H need not be defined explicitly. QPHESS is not accessed if LP is set to .TRUE.. and in this case QPHESS may be the dummy routine E04NAN. (E04NAN is included in the NAG Foundation Library and so need not be supplied by the user. Its name may be implementation-dependent: see the Users' Note for your implementation for details.)

Its specification is:

```

SUBROUTINE QPHESS (N, NROWH, NCOLH, JTHCOL,
1                HESS, X, HX)
  INTEGER          N, NROWH, NCOLH, JTHCOL
  DOUBLE PRECISION HESS(NROWH,NCOLH), X(N), HX(N)

```

- 1: N -- INTEGER Input
 On entry: the number n of variables.
- 2: NROWH -- INTEGER Input
 On entry: the row dimension of the array HESS.
- 3: NCOLH -- INTEGER Input
 On entry: the column dimension of the array HESS.
- 4: JTHCOL -- INTEGER Input
 The input parameter JTHCOL is included to allow flexibility for the user in the special situation when x is the jth co-ordinate vector (i.e., the jth column of the identity matrix). This may be of interest because

the product Hx is then the j th column of H , which can sometimes be computed very efficiently. The user may code QPHESS to take advantage of this case. On entry: if $JTHCOL = j$, where $j > 0$, HX must contain column $JTHCOL$ of H , and hence special code may be included in QPHESS to test $JTHCOL$ if desired. However, special code is not necessary, since the vector x always contains column $JTHCOL$ of the identity matrix whenever QPHESS is called with $JTHCOL > 0$.

- 5: HESS(NROWH,NCOLH) -- DOUBLE PRECISION array Input
On entry: the Hessian matrix H .

In some cases, it may be desirable to use a one-dimensional array to transmit data or workspace to QPHESS; HESS should then be declared with dimension (NROWH) in the (sub)program from which E04NAF is called and the parameter NCOLH must be 1.

In other situations, it may be desirable to compute Hx without accessing HESS - for example, if H is sparse or has special structure. (This is illustrated in the subroutine QPHES1 in the example program in Section 9.) The parameters HESS, NROWH and NCOLH may then refer to any convenient array.

When $MSGLVL = 99$, the (possibly undefined) contents of HESS will be printed, except if NROWH and NCOLH are both 1. Also printed are the results of calling QPHESS with $JTHCOL = 1, 2, \dots, n$.

- 6: X(N) -- DOUBLE PRECISION array Input
On entry: the vector x .

- 7: HX(N) -- DOUBLE PRECISION array Output
On exit: HX must contain the product Hx .

QPHESS must be declared as EXTERNAL in the (sub)program from which E04NAF is called. Parameters denoted as Input must not be changed by this procedure.

- 17: COLD -- LOGICAL Input
On entry: COLD must indicate whether the user has specified an initial estimate of the active set of constraints. If COLD is set to .TRUE., the initial working set is determined by E04NAF. If COLD is set to .FALSE. (a 'warm start'), the user must define the ISTATE array which gives the status of

each constraint with respect to the working set. E04NAF will override the user's specification of ISTATE if necessary, so that a poor choice of working set will not cause a fatal error.

The warm start option is particularly useful when E04NAF is called repeatedly to solve related problems.

- 18: LP -- LOGICAL Input
 On entry: if LP = .FALSE., E04NAF will solve the specified quadratic programming problem. If LP = .TRUE., E04NAF will treat H as zero and solve the resulting linear programming problem; in this case, the parameters HESS and QPHESS will not be referenced.
- 19: ORTHOG -- LOGICAL Input
 On entry: ORTHOG must indicate whether orthogonal transformations are to be used in computing and updating the TQ factorization of the working set

$$A \begin{matrix} Q \\ 0 \end{matrix} \begin{matrix} T \\ T \end{matrix},$$

$$\begin{matrix} S \\ S \end{matrix}$$
 where A is a sub-matrix of A and T is reverse-triangular.

$$\begin{matrix} S \\ S \end{matrix}$$
 If ORTHOG = .TRUE., the TQ factorization is computed using Householder reflections and plane rotations, and the matrix Q is orthogonal. If ORTHOG = .FALSE., stabilized elementary transformations are used to maintain the factorization, and Q is not orthogonal. A rule of thumb in making the choice is that orthogonal transformations require more work, but provide greater numerical stability. Thus, we recommend setting ORTHOG to .TRUE. if the problem is reasonably small or the active set is ill-conditioned. Otherwise, setting ORTHOG to .FALSE. will often lead to a reduction in solution time with negligible loss of reliability.
- 20: X(N) -- DOUBLE PRECISION array Input/Output
 On entry: an estimate of the solution. In the absence of better information all elements of X may be set to zero. On exit: from E04NAF, X contains the best estimate of the solution.
- 21: ISTATE(NCTOTL) -- INTEGER array Input/Output
 On entry: with COLD as .FALSE., ISTATE must indicate the status of every constraint with respect to the working set. The ordering of ISTATE is as follows; the first n elements of ISTATE refer to the upper and lower bounds on the

variables and elements $n+1$ through $n + NCLIN$ refer to the upper and lower bounds on Ax . The significance of each possible value of $ISTATE(j)$ is as follows:

$ISTATE(j)$ Meaning

- 2 The constraint violates its lower bound by more than $FEATOL(j)$. This value of $ISTATE$ cannot occur after a feasible point has been found.
- 1 The constraint violates its upper bound by more than $FEATOL(j)$. This value of $ISTATE$ cannot occur after a feasible point has been found.
- 0 The constraint is not in the working set. Usually, this means that the constraint lies strictly between its bounds.
- 1 This inequality constraint is included in the working set at its lower bound. The value of the constraint is within $FEATOL(j)$ of its lower bound.
- 2 This inequality constraint is included in the working set at its upper bound. The value of the constraint is within $FEATOL(j)$ of its upper bound.
- 3 The constraint is included in the working set as an equality. This value of $ISTATE$ can occur only when $BL(j) = BU(j)$. The corresponding constraint is within $FEATOL(j)$ of its required value.

If $COLD = .TRUE.$, $ISTATE$ need not be set by the user. However, when $COLD = .FALSE.$, every element of $ISTATE$ must be set to one of the values given above to define a suggested initial working set (which will be changed by $EO4NAF$ if necessary). The most likely values are:

$ISTATE(j)$ Meaning

- 0 The corresponding constraint should not be in the initial working set.
- 1 The constraint should be in the initial working set at its lower bound.
- 2 The constraint should be in the initial working set at its upper bound.
- 3 The constraint should be in the initial working

set as an equality. This value must not be specified unless $BL(j) = BU(j)$. The values 1, 2 or 3 all have the same effect when $BL(j) = BU(j)$.

Note that if E04NAF has been called previously with the same values of N and NCLIN, ISTATE already contains satisfactory values. On exit: when E04NAF exits with IFAIL set to 0, 1 or 3, the values in the array ISTATE indicate the status of the constraints in the active set at the solution. Otherwise, ISTATE indicates the composition of the working set at the final iterate.

22: ITER -- INTEGER Output
On exit: the number of iterations performed in either the LP phase or the QP phase, whichever was last entered.

Note that ITER is reset to zero after the LP phase.

23: OBJ -- DOUBLE PRECISION Output
On exit: the value of the quadratic objective function at x if x is feasible ($IFAIL \leq 5$), or the sum of infeasibilities at x otherwise ($6 \leq IFAIL \leq 8$).

24: CLAMDA(NCTOTL) -- DOUBLE PRECISION array Output
On exit: the values of the Lagrange multiplier for each constraint with respect to the current working set. The ordering of CLAMDA is as follows; the first n components contain the multipliers for the bound constraints on the variables, and the remaining components contain the multipliers for the general linear constraints. If $ISTATE(j) = 0$ (i.e., constraint j is not in the working set), $CLAMDA(j)$ is zero. If x is optimal and $ISTATE(j) = 1$, $CLAMDA(j)$ should be non-negative; if $ISTATE(j) = 2$, $CLAMDA(j)$ should be non-positive.

25: IWORK(LIWORK) -- INTEGER array Workspace

26: LIWORK -- INTEGER Input
On entry:
the dimension of the array IWORK as declared in the (sub)program from which E04NAF is called.
Constraint: $LIWORK \geq 2 \times N$.

27: WORK(LWORK) -- DOUBLE PRECISION array Workspace

28: LWORK -- INTEGER Input
On entry:

the dimension of the array WORK as declared in the (sub)program from which E04NAF is called.

Constrain if LP = .FALSE. or NCLIN >= N then

```
nts:                2
                    LWORK>=2*N +4*N*NCLIN+NROWA.
```

if LP = .TRUE. and NCLIN < N then

```
                2
                    LWORK>=2*(NCLIN+1) +4*N+2*NCLIN+NROWA.
```

If MSGVLV > 0, the amount of workspace provided and the amount of workspace required are output on the current advisory message unit (as defined by X04ABF). As an alternative to computing LWORK from the formula given above, the user may prefer to obtain an appropriate value from the output of a preliminary run with a positive value of MSGVLV and LWORK set to 1 (E04NAF will then terminate with IFAIL = 9).

- 29: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL /=0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit. To suppress the output of an error message when soft failure occurs, set IFAIL to 1.

IFAIL contains zero on exit if x is a strong local minimum. i.e., the projected gradient is negligible, the Lagrange multipliers are optimal, and the projected Hessian is positive-definite. In some cases, a zero value of IFAIL means that x is a global minimum (e.g. when the Hessian matrix is positive-definite).

5.1. Description of the Printed Output

When MSGVLV >= 5, a line of output is produced for every change in the working set (thus, several lines may be printed during a single iteration).

To aid interpretation of the printed results, we mention the convention for numbering the constraints: indices 1 through to n refer to the bounds on the variables, and when $NCLIN > 0$ indices $n+1$ through to $n + NCLIN$ refer to the general constraints. When the status of a constraint changes, the index of the constraint is printed, along with the designation L (lower bound), U (upper bound) or E (equality).

In the LP phase, the printout includes the following:

ITN	is the iteration count.
JDEL	is the index of the constraint deleted from the working set. If JDEL is zero, no constraint was deleted.
JADD	is the index of the constraint added to the working set. If JADD is zero, no constraint was added.
STEP	is the step taken along the computed search direction.
COND T	is a lower bound on the condition number of the matrix of predicted active constraints.
NUMINF	is the number of violated constraints (infeasibilities).
SUMINF	is a weighted sum of the magnitudes of the constraint violations.
LPOBJ	is the value of the linear objective function $c^T x$. It is printed only if LP = .TRUE..

During the QP phase, the printout includes the following:

ITN	is the iteration count (reset to zero after the LP phase).
JDEL	is the index of the constraint deleted from the working set. If JDEL is zero, no constraint was deleted.
JADD	is the index of the constraint added to the

	working set. If JADD is zero, no constraint was added.
STEP	is the step (α) taken along the direction of k search (if STEP is 1.0, the current point is a minimum in the subspace defined by the current working set).
NHESS	is the number of calls to subroutine QPHESS.
OBJECTIVE	is the value of the quadratic objective function.
NCOLZ	is the number of columns of Z (see Section 3). In general, it is the dimension of the subspace in which the quadratic is currently being minimized.
NORM GFREE	is the Euclidean norm of the gradient of the objective function with respect to the free variables, i.e. variables not currently held at a bound (NORM GFREE is not printed if ORTHOG = . FALSE.). In some cases, the objective function and gradient are updated rather than recomputed. If so, this entry will be -- to indicate that the gradient with respect to the free variables has not been computed.
NORM QTG	is a weighted norm of the gradient of the objective function with respect to the free variables (NORM QTG is not printed if ORTHOG = . TRUE.). In some cases, the objective function and gradient are updated rather than recomputed. If so, this entry will be -- to indicate that the gradient with respect to the free variables has not been computed.
NORM ZTG	is the Euclidean norm of the projected gradient (see Section 3).
COND T	is a lower bound on the condition number of the matrix of constraints in the working set.
COND ZHZ	is a lower bound on the condition number of the projected Hessian matrix.
HESS MOD	is the correction added to the diagonal of the

projected Hessian to ensure that a satisfactory Cholesky factorization exists (see Section 3). When the projected Hessian is sufficiently positive-definite, HESS MOD will be zero.

When MSGVLV = 1 or MSGVLV \geq 10, the summary printout at the end of execution of E04NAF includes a listing of the status of every constraint. Note that default names are assigned to all variables and constraints.

The following describes the printout for each variable.

VARBL	is the name (V) and index j, $j=1,2,\dots,n$, of the variable.
STATE	gives the state of the variable (FR if neither bound is in the working set, EQ if a fixed variable, LL if on its lower bound, UL if on its upper bound, TB if held on a temporary bound). If VALUE lies outside the upper or lower bounds by more than FEATOL(j), STATE will be ++ or -- respectively.
VALUE	is the value of the variable at the final iteration.
LOWER BOUND	is the lower bound specified for the variable.
UPPER BOUND	is the upper bound specified for the variable.
LAGR MULT	is the value of the Lagrange multiplier for the associated bound constraint. This will be zero if STATE is FR. If x is optimal and STATE is LL, the multiplier should be non-negative; if STATE is UL, the multiplier should be non-positive.
RESIDUAL	is the difference between the variable and the nearer of its bounds BL(j) and BU(j).

For each of the general constraints the printout is as above with refers to the jth element of Ax, except that VARBL is replaced by

LNCON	The name (L) and index j, $j=1,2,\dots,NCLIN$, of the constraint.
-------	--

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

IFAIL= 1

x is a weak local minimum (the projected gradient is negligible, the Lagrange multipliers are optimal, but the projected Hessian is only semi-definite). This means that the solution is not unique.

IFAIL= 2

The solution appears to be unbounded, i.e., the quadratic function is unbounded below in the feasible region. This value of IFAIL occurs when a step of infinity would have to be taken in order to continue the algorithm.

IFAIL= 3

x appears to be a local minimum, but optimality cannot be verified because some of the Lagrange multipliers are very small in magnitude.

E04NAF has probably found a solution. However, the presence of very small Lagrange multipliers means that the predicted active set may be incorrect, or that x may be only a constrained stationary point rather than a local minimum. The method in E04NAF is not guaranteed to find the correct active set when there are very small multipliers. E04NAF attempts to delete constraints with zero multipliers, but this does not necessarily resolve the issue. The determination of the correct active set is a combinatorial problem that may require an extremely large amount of time. The occurrence of small multipliers often (but not always) indicates that there are redundant constraints.

IFAIL= 4

The iterates of the QP phase could be cycling, since a total of 50 changes were made to the working set without altering x.

This value will occur if 50 iterations are performed in the QP phase without changing x. The user should check the printed output for a repeated pattern of constraint deletions and additions. If a sequence of constraint changes is being repeated, the iterates are probably cycling. (E04NAF does not contain a method that is guaranteed to avoid cycling, which would be combinatorial in nature.) Cycling may occur in two circumstances: at a constrained

stationary point where there are some small or zero Lagrange multipliers (see the discussion of IFAIL = 3); or at a point (usually a vertex) where the constraints that are satisfied exactly are nearly linearly dependent. In the latter case, the user has the option of identifying the offending dependent constraints and removing them from the problem, or restarting the run with larger values of FEATOL for nearly dependent constraints. If E04NAF terminates with IFAIL = 4, but no suspicious pattern of constraint changes can be observed, it may be worthwhile to restart with the final x (with or without the warm start option).

IFAIL= 5

The limit of ITMAX iterations was reached in the QP phase before normal termination occurred.

The value of ITMAX may be too small. If the method appears to be making progress (e.g. the objective function is being satisfactorily reduced), increase ITMAX and rerun E04NAF (possibly using the warm start facility to specify the initial working set). If ITMAX is already large, but some of the constraints could be nearly linearly dependent, check the output for a repeated pattern of constraints entering and leaving the working set. (Near-dependencies are often indicated by wide variations in size in the diagonal elements of the T matrix, which will be printed if MSGLEV \geq 30.) In this case, the algorithm could be cycling (see the comments for IFAIL = 4).

IFAIL= 6

The LP phase terminated without finding a feasible point, and hence it is not possible to satisfy all the constraints to within the tolerances specified by the FEATOL array. In this case, the final iterate will reveal values for which there will be a feasible point (e.g. a feasible point will exist if the feasibility tolerance for each violated constraint exceeds its RESIDUAL at the final point). The modified problem (with altered values in FEATOL) may then be solved using a warm start.

The user should check that there are no constraint redundancies. If the data for the jth constraint are accurate only to the absolute precision (δ), the user should ensure that the value of FEATOL(j) is greater than (δ). For example, if all elements of A are of order unity and are accurate only to three decimal places, every

-3

component of FEATOL should be at least 10^{-3} .

IFAIL= 7

The iterates may be cycling during the LP phase; see the comments above under IFAIL = 4.

IFAIL= 8

The limit of ITMAX iterations was reached during the LP phase. See comments above under IFAIL = 5.

IFAIL= 9

An input parameter is invalid.

Overflow

If the printed output before the overflow error contains a warning about serious ill-conditioning in the working set when adding the j th constraint, it may be possible to avoid the difficulty by increasing the magnitude of FEATOL(j) and rerunning the program. If the message recurs even after this change, the offending linearly dependent constraint (with index j) must be removed from the problem. If a warning message did not precede the fatal overflow, the user should contact NAG.

7. Accuracy

The routine implements a numerically stable active set strategy and returns solutions that are as accurate as the condition of the QP problem warrants on the machine.

8. Further Comments

The number of iterations depends upon factors such as the number of variables and the distances of the starting point from the solution. The number of operations performed per iteration is

2

roughly proportional to $(N_{FREE})^2$, where N_{FREE} ($N_{FREE} \leq n$) is the number of variables fixed on their upper or lower bounds.

Sensible scaling of the problem is likely to reduce the number of iterations required and make the problem less sensitive to perturbations in the data, thus improving the condition of the QP problem. See the Chapter Introduction and Gill et al [1] for further information and advice.

9. Example

To minimize the function $c^T x + \frac{1}{2} x^T H x$, where

$c = [-0.02, -0.2, -0.2, -0.2, -0.2, 0.04, 0.04]^T$

$H = \begin{bmatrix} 2 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 2 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 2 & 2 & 0 & 0 & 0 \\ 0 & 0 & 2 & 2 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 2 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -2 & -2 \\ 0 & 0 & 0 & 0 & 0 & -2 & -2 \end{bmatrix}$

subject to the bounds

E04 -- Minimizing or Maximizing a Function

E04UCF

E04UCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

Note for users via the AXIOM system: the interface to this routine has been enhanced for use with AXIOM and is slightly different to that offered in the standard version of the Foundation Library. In particular, the optional parameters of the NAG routine are now included in the parameter list. These are described in section 5.1.2, below.

1. Purpose

E04UCF is designed to minimize an arbitrary smooth function subject to constraints, which may include simple bounds on the variables, linear constraints and smooth nonlinear constraints. (E04UCF may be used for unconstrained, bound-constrained and linearly constrained optimization.) The user must provide subroutines that define the objective and constraint functions and as many of their first partial derivatives as possible. Unspecified derivatives are approximated by finite differences.

All matrices are treated as dense, and hence E04UCF is not intended for large sparse problems.

E04UCF uses a sequential quadratic programming (SQP) algorithm in which the search direction is the solution of a quadratic programming (QP) problem. The algorithm treats bounds, linear constraints and nonlinear constraints separately.

2. Specification

```

SUBROUTINE E04UCF (N, NCLIN, NCNLN, NROWA, NROWJ, NROWR,

3. Description

E04UCF is designed to solve the nonlinear programming problem -- the minimization of a smooth nonlinear function subject to a set of constraints on the variables. The problem is assumed to be stated in the following form:

$$\begin{array}{ll}
 \text{Minimize} & F(x) \\
 \text{subject to} & l \leq \{A x\} \leq u, \\
 & \{L\} \\
 x \text{ is in } R & \{c(x)\}
 \end{array} \quad (1)$$

where $F(x)$, the objective function, is a nonlinear function, A

is an n by n constant matrix, and $c(x)$ is an n element vector L
 L of nonlinear constraint functions. (The matrix A and the vector N
 L $c(x)$ may be empty.) The objective function and the constraint functions are assumed to be smooth, i.e., at least twice-continuously differentiable. (The method of E04UCF will usually solve (1) if there are only isolated discontinuities away from the solution.)

This routine is essentially identical to the subroutine SOL/NPSOL described in Gill et al [8].

Note that upper and lower bounds are specified for all the variables and for all the constraints.

An equality constraint can be specified by setting $l_i = u_i$. If certain bounds are not present, the associated elements of l or u can be set to special values that will be treated as -infty or +infty.

If there are no nonlinear constraints in (1) and F is linear or quadratic then one of E04MBF, E04NAF or E04NCF(*) will generally be more efficient. If the problem is large and sparse the MINOS package (see Murtagh and Saunders [13]) should be used, since E04UCF treats all matrices as dense.

The user must supply an initial estimate of the solution to (1), together with subroutines that define $F(x)$, $c(x)$ and as many first partial derivatives as possible; unspecified derivatives are approximated by finite differences.

The objective function is defined by subroutine OBJFUN, and the nonlinear constraints are defined by subroutine CONFUN. On every call, these subroutines must return appropriate values of the objective and nonlinear constraints. The user should also provide the available partial derivatives. Any unspecified derivatives are approximated by finite differences; see Section 5.1 for a discussion of the optional parameter Derivative Level. Just before either OBJFUN or CONFUN is called, each element of the current gradient array OBJGRD or CJAC is initialised to a special value. On exit, any element that retains the value is estimated by finite differences. Note that if there are nonlinear constraints, then the first call to CONFUN will precede the first

call to OBJFUN.

For maximum reliability, it is preferable for the user to provide all partial derivatives (see Chapter 8 of Gill et al [10], for a detailed discussion). If all gradients cannot be provided, it is similarly advisable to provide as many as possible. While developing the subroutines OBJFUN and CONFUN, the optional parameter Verify (see Section 5.1) should be used to check the calculation of any known gradients.

E04UCF implements a sequential quadratic programming (SQP) method. The document for E04NCF(*) should be consulted in conjunction with this document.

In the rest of this section we briefly summarize the main features of the method of E04UCF. Where possible, explicit reference is made to the names of variables that are parameters of subroutines E04UCF or appear in the printed output (see Section 5.2).

At a solution of (1), some of the constraints will be active, i.e., satisfied exactly. An active simple bound constraint implies that the corresponding variable is fixed at its bound, and hence the variables are partitioned into fixed and free variables. Let C denote the m by n matrix of gradients of the active general linear and nonlinear constraints. The number of fixed variables will be denoted by n_{FX} , with $n_{FR} = n - n_{FX}$ the number of free variables. The subscripts 'FX' and 'FR' on a vector or matrix will denote the vector or matrix composed of the components corresponding to fixed or free variables.

A point x is a first-order Kuhn-Tucker point for (1) (see, e.g., Powell [14]) if the following conditions hold:

(i) x is feasible;

(ii) there exist vectors (λ_i) and (λ_{FR}) (the Lagrange multiplier vectors for the bound and general constraints) such that

$$g^T = C^T (\lambda_{FR}) + (\lambda_i), \quad (2)$$

where g is the gradient of F evaluated at x , and $(\lambda_i) = 0$ if

the j th variable is free.

(iii) The Lagrange multiplier corresponding to an inequality constraint active at its lower bound must be non-negative, and non-positive for an inequality constraint active at its upper bound.

Let Z denote a matrix whose columns form a basis for the set of vectors orthogonal to the rows of C ; i.e., $CZ=0$. An

FR FR

equivalent statement of the condition (2) in terms of Z is

$$\begin{matrix} T \\ Z^T g \\ \text{FR} \end{matrix} = 0.$$

T

The vector $Z^T g$ is termed the projected gradient of F at x .

FR

Certain additional conditions must be satisfied in order for a first-order Kuhn-Tucker point to be a solution of (1) (see, e.g., Powell [14]).

The method of E04UCF is a sequential quadratic programming (SQP) method. For an overview of SQP methods, see, for example, Fletcher [5], Gill et al [10] and Powell [15].

The basic structure of E04UCF involves major and minor iterations. The major iterations generate a sequence of iterates

*

$\{x_k\}$ that converge to x^* , a first-order Kuhn-Tucker point of (1).

At a typical major iteration, the new iterate \bar{x} is defined by

$$\bar{x} = x + (\alpha)p \tag{3}$$

where x is the current iterate, the non-negative scalar (α) is the step length, and p is the search direction. (For simplicity, we shall always consider a typical iteration and avoid reference to the index of the iteration.) Also associated with each major iteration are estimates of the Lagrange multipliers and a prediction of the active set.

The search direction p in (3) is the solution of a quadratic programming subproblem of the form

$$\begin{array}{ll} \text{Minimize} & \frac{1}{2} g^T p + \frac{1}{2} p^T H p, \\ \text{subject to} & \begin{array}{l} l \leq \{A\} p \leq u, \\ \{L\} \\ \{A\} \\ \{N\} \end{array} \end{array} \quad (4)$$

where g is the gradient of F at x , the matrix H is a positive-definite quasi-Newton approximation to the Hessian of the Lagrangian function (see Section 8.3), and A is the Jacobian matrix of c evaluated at x . (Finite-difference estimates may be used for g and A ; see the optional parameter Derivative Level in Section 5.1.) Let l in (4) be partitioned into three sections: l_B , l_L and l_N , corresponding to the bound, linear and nonlinear

constraints. The vector \bar{l} in (4) is similarly partitioned, and is defined as

$$\bar{l}_B = l_B - x, \quad \bar{l}_L = l_L - A_L x, \quad \text{and} \quad \bar{l}_N = l_N - c,$$

where c is the vector of nonlinear constraints evaluated at x .

The vector \bar{u} is defined in an analogous fashion.

The estimated Lagrange multipliers at each major iteration are the Lagrange multipliers from the subproblem (4) (and similarly for the predicted active set). (The numbers of bounds, general linear and nonlinear constraints in the QP active set are the quantities Bnd, Lin and Nln in the printed output of E04UCF.) In E04UCF, (4) is solved using E04NCF(*). Since solving a quadratic program as an iterative procedure, the minor iterations of E04UCF are the iterations of E04NCF(*). (More details about solving the subproblem are given in Section 8.1.)

Certain matrices associated with the QP subproblem are relevant in the major iterations. Let the subscripts 'FX' and 'FR' refer to the predicted fixed and free variables, and let C denote the m by n matrix of gradients of the general linear and nonlinear constraints in the predicted active set. First, we have available the TQ factorization of C :

$$C = Q R$$

$$\begin{pmatrix} C & Q \\ FR & FR \end{pmatrix} = \begin{pmatrix} 0 & T \end{pmatrix}, \quad (5)$$

where T is a nonsingular m by m reverse-triangular matrix (i.e., $t_{ij} = 0$ if $i+j < m$), and the non-singular n by n matrix Q is the product of orthogonal transformations (see Gill et al [6]). Second, we have the upper-triangular Cholesky factor R of the transformed and re-ordered Hessian matrix

$$\begin{pmatrix} T & \\ R & R=H \end{pmatrix} = \begin{pmatrix} T \\ Q \end{pmatrix} \begin{pmatrix} T^T & \\ & HQ \end{pmatrix}, \quad (6)$$

where H is the Hessian H with rows and columns permuted so that the free variables are first, and Q is the n by n matrix

$$Q = \begin{pmatrix} (Q &) \\ (FR &) \\ (I &) \\ (FX &) \end{pmatrix}, \quad (7)$$

with I the identity matrix of order n . If the columns of Q are partitioned so that

$$\begin{pmatrix} Q \\ FR \end{pmatrix} = \begin{pmatrix} Z & Y \end{pmatrix},$$

the n ($n = n - m$) columns of Z form a basis for the null space of

C . The matrix Z is used to compute the projected gradient $Z^T g$ at the current iterate. (The values Nz , $\text{Norm } Gf$ and $\text{Norm } Gz$

printed by E04UCF give n and the norms of g and $Z^T g$.)

A theoretical characteristic of SQP methods is that the predicted active set from the QP subproblem (4) is identical to the correct

active set in a neighbourhood of x^* . In E04UCF, this feature is exploited by using the QP active set from the previous iteration as a prediction of the active set for the next QP subproblem,

which leads in practice to optimality of the subproblems in only one iteration as the solution is approached. Separate treatment of bound and linear constraints in E04UCF also saves computation in factorizing C and H .

FR Q

Once p has been computed, the major iteration proceeds by determining a step length (α) that produces a 'sufficient decrease' in an augmented Lagrangian merit function (see Section 8.2). Finally, the approximation to the transformed Hessian matrix H is updated using a modified BFGS quasi-Newton update

Q

(see Section 8.3) to incorporate new curvature information

obtained in the move from x to \bar{x} .

On entry to E04UCF, an iterative procedure from E04NCF(*) is executed, starting with the user-provided initial point, to find a point that is feasible with respect to the bounds and linear constraints (using the tolerance specified by Linear Feasibility Tolerance see Section 5.1). If no feasible point exists for the bound and linear constraints, (1) has no solution and E04UCF terminates. Otherwise, the problem functions will thereafter be evaluated only at points that are feasible with respect to the bounds and linear constraints. The only exception involves variables whose bounds differ by an amount comparable to the finite-difference interval (see the discussion of Difference Interval in Section 5.1). In contrast to the bounds and linear constraints, it must be emphasised that the nonlinear constraints will not generally be satisfied until an optimal point is reached.

Facilities are provided to check whether the user-provided gradients appear to be correct (see the optional parameter Verify in Section 5.1). In general, the check is provided at the first point that is feasible with respect to the linear constraints and bounds. However, the user may request that the check be performed at the initial point.

In summary, the method of E04UCF first determines a point that satisfies the bound and linear constraints. Thereafter, each iteration includes:

- (a) the solution of a quadratic programming subproblem;
- (b) a linesearch with an augmented Lagrangian merit function;

and

- (c) a quasi-Newton update of the approximate Hessian of the Lagrangian function.

These three procedures are described in more detail in Section 8.

5. Parameters

- 1: N -- INTEGER Input
 On entry: the number, n, of variables in the problem.
 Constraint: N > 0.
- 2: NCLIN -- INTEGER Input
 On entry: the number, n , of general linear constraints in

L

 the problem. Constraint: NCLIN >= 0.
- 3: NCNLN -- INTEGER Input
 On entry: the number, n , of nonlinear constraints in the

N

 problem. Constraint: NCNLN >= 0.
- 4: NROWA -- INTEGER Input
 On entry:
 the first dimension of the array A as declared in the
 (sub)program from which E04UCF is called.

Constraint: $NROWA \geq \max(1, NCLIN)$.

5: $NROWJ$ -- INTEGER Input

On entry:

the first dimension of the array CJAC as declared in the (sub)program from which E04UCF is called.

Constraint: $NROWJ \geq \max(1, NCNLN)$.

6: $NROWR$ -- INTEGER Input

On entry:

the first dimension of the array R as declared in the (sub)program from which E04UCF is called.

Constraint: $NROWR \geq N$.

7: $A(NROWA, *)$ -- DOUBLE PRECISION array Input

The second dimension of the array A must be $\geq N$ for $NCLIN > 0$. On entry: the i th row of the array A must contain the i th row of the matrix A of general linear constraints in (1).

L

That is, the i th row contains the coefficients of the i th general linear constraint, for $i = 1, 2, \dots, NCLIN$.

If $NCLIN = 0$ then the array A is not referenced.

8: $BL(N+NCLIN+NCNLN)$ -- DOUBLE PRECISION array Input

On entry: the lower bounds for all the constraints, in the following order. The first n elements of BL must contain the lower bounds on the variables. If $NCLIN > 0$, the next n

L

elements of BL must contain the lower bounds on the general linear constraints. If $NCNLN > 0$, the next n elements of BL

N

must contain the lower bounds for the nonlinear constraints. To specify a non-existent lower bound (i.e., $l = -\infty$), the

j

value used must satisfy $BL(j) \leq -BIGBND$, where BIGBND is the value of the optional parameter Infinite Bound Size whose

10

default value is 10 (see Section 5.1). To specify the j th constraint as an equality, the user must set $BL(j) = BU(j) = (beta)$, say, where $|(beta)| < BIGBND$. Constraint: $BL(j) \leq BU(j)$, for $j = 1, 2, \dots, N+NCLIN+NCNLN$.

9: $BU(N+NCLIN+NCNLN)$ -- DOUBLE PRECISION array Input

On entry: the upper bounds for all the constraints in the following order. The first n elements of BU must contain the

upper bounds on the variables. If $NCLIN > 0$, the next n elements of BU must contain the upper bounds on the general linear constraints. If $NCNLN > 0$, the next n elements of BU must contain the upper bounds for the nonlinear constraints. To specify a non-existent upper bound (i.e., $u = +\infty$), the value used must satisfy $BU(j) \geq BIGBND$, where $BIGBND$ is the value of the optional parameter Infinite Bound Size, whose default value is 10 (see Section 5.1). To specify the j th constraint as an equality, the user must set $BU(j) = BL(j) = (beta)$, say, where $|(beta)| < BIGBND$. Constraint: $BU(j) \geq BL(j)$, for $j=1,2,\dots,N+NCLIN+NCNLN$.

10: CONFUN -- SUBROUTINE, supplied by the user.

External Procedure
CONFUN must calculate the vector $c(x)$ of nonlinear constraint functions and (optionally) its Jacobian for a specified n element vector x . If there are no nonlinear constraints ($NCNLN=0$), CONFUN will never be called by E04UCF and CONFUN may be the dummy routine E04UDM. (E04UDM is included in the NAG Foundation Library and so need not be supplied by the user. Its name may be implementation-dependent: see the Users' Note for your implementation for details.) If there are nonlinear constraints, the first call to CONFUN will occur before the first call to OBJFUN.

Its specification is:

```

SUBROUTINE CONFUN (MODE, NCNLN, N, NROWJ, NEEDC,
1                  X, C, CJAC, NSTATE, IUSER,
2                  USER)
  INTEGER          MODE, NCNLN, N, NROWJ, NEEDC
1                  (NCNLN), NSTATE, IUSER(*)
  DOUBLE PRECISION X(N), C(NCNLN), CJAC(NROWJ,N),
1                  USER(*)

```

1: MODE -- INTEGER Input/Output

On entry: MODE indicates the values that must be assigned during each call of CONFUN. MODE will always have the value 2 if all elements of the Jacobian are available, i.e., if Derivative Level is either 2 or 3 (see Section 5.1). If some elements of CJAC are unspecified, E04UCF will call CONFUN with $MODE = 0, 1$,

or 2:

If MODE = 2, only the elements of C corresponding to positive values of NEEDC must be set (and similarly for the available components of the rows of CJAC).

If MODE = 1, the available components of the rows of CJAC corresponding to positive values in NEEDC must be set. Other rows of CJAC and the array C will be ignored.

If MODE = 0, the components of C corresponding to positive values in NEEDC must be set. Other components and the array CJAC are ignored. On exit: MODE may be set to a negative value if the user wishes to terminate the solution to the current problem. If MODE is negative on exit from CONFUN then E04UCF will terminate with IFAIL set to MODE.

- | | | |
|----|--|--------|
| 2: | NCNLN -- INTEGER | Input |
| | On entry: the number, n , of nonlinear constraints. | |
| | N | |
| 3: | N -- INTEGER | Input |
| | On entry: the number, n, of variables. | |
| 4: | NROWJ -- INTEGER | Input |
| | On entry: the first dimension of the array CJAC. | |
| 5: | NEEDC(NCNLN) -- INTEGER array | Input |
| | On entry: the indices of the elements of C or CJAC that must be evaluated by CONFUN. If NEEDC(i)>0 then the ith element of C and/or the ith row of CJAC (see parameter MODE above) must be evaluated at x. | |
| 6: | X(N) -- DOUBLE PRECISION array | Input |
| | On entry: the vector x of variables at which the constraint functions are to be evaluated. | |
| 7: | C(NCNLN) -- DOUBLE PRECISION array | Output |
| | On exit: if NEEDC(i)>0 and MODE = 0 or 2, C(i) must contain the value of the ith constraint at x. The remaining components of C, corresponding to the non-positive elements of NEEDC, are ignored. | |
| 8: | CJAC(NROWJ,N) -- DOUBLE PRECISION array | Output |

On exit: if $NEEDC(i) > 0$ and $MODE = 1$ or 2 , the i th row of $CJAC$ must contain the available components of the vector $(\nabla c)_i$ given by

$$(\nabla c)_i = \begin{pmatrix} \frac{\partial c}{\partial x_1} & \frac{\partial c}{\partial x_2} & \dots & \frac{\partial c}{\partial x_n} \end{pmatrix}^T$$

where $\frac{\partial c}{\partial x_j}$ is the partial derivative of the i th constraint with respect to the j th variable, evaluated at the point x . See also the parameter $NSTATE$ below. The remaining rows of $CJAC$, corresponding to non-positive elements of $NEEDC$, are ignored.

If all constraint gradients (Jacobian elements) are known (i.e., Derivative Level = 2 or 3; see Section 5.1) any constant elements may be assigned to $CJAC$ one time only at the start of the optimization. An element of $CJAC$ that is not subsequently assigned in $CONFUN$ will retain its initial value throughout. Constant elements may be loaded into $CJAC$ either before the call to $E04UCF$ or during the first call to $CONFUN$ (signalled by the value $NSTATE = 1$). The ability to preload constants is useful when many Jacobian elements are identically zero, in which case $CJAC$ may be initialised to zero and non-zero elements may be reset by $CONFUN$.

Note that constant non-zero elements do affect the values of the constraints. Thus, if $CJAC(i,j)$ is set to a constant value, it need not be reset in subsequent calls to $CONFUN$, but the value $CJAC(i,j) \cdot X(j)$ must nonetheless be added to $C(i)$.

It must be emphasized that, if Derivative Level < 2, unassigned elements of $CJAC$ are not treated as constant; they are estimated by finite differences, at non-trivial expense. If the user does not supply a value for Difference Interval (see Section 5.1), an interval for each component of x is computed automatically at the start of the optimization. The automatic procedure can usually identify constant

elements of CJAC, which are then computed once only by finite differences.

9: NSTATE -- INTEGER Input
 On entry: if NSTATE = 1 then E04UCF is calling CONFUN for the first time. This parameter setting allows the user to save computation time if certain data must be read or calculated only once.

10: IUSER(*) -- INTEGER array User Workspace

11: USER(*) -- DOUBLE PRECISION array User Workspace
 CONFUN is called from E04UCF with the parameters IUSER and USER as supplied to E04UCF. The user is free to use the arrays IUSER and USER to supply information to CONFUN as an alternative to using COMMON.

CONFUN must be declared as EXTERNAL in the (sub)program from which E04UCF is called. Parameters denoted as Input must not be changed by this procedure.

11: OBJFUN -- SUBROUTINE, supplied by the user.

External Procedure

OBJFUN must calculate the objective function $F(x)$ and (optionally) the gradient $g(x)$ for a specified n element vector x .

Its specification is:

```

SUBROUTINE OBJFUN (MODE, N, X, OBJF, OBJGRD,
1                 NSTATE, IUSER, USER)
  INTEGER          MODE, N, NSTATE, IUSER(*)
  DOUBLE PRECISION X(N), OBJF, OBJGRD(N), USER(*)

```

1: MODE -- INTEGER Input/Output
 On entry: MODE indicates the values that must be assigned during each call of OBJFUN.

MODE will always have the value 2 if all components of the objective gradient are specified by the user, i.e., if Derivative Level is either 1 or 3. If some gradient elements are unspecified, E04UCF will call OBJFUN with MODE = 0, 1 or 2.

If MODE = 2, compute OBJF and the available components of OBJGRD.

If MODE = 1, compute all available components of

OBJGRD; OBJF is not required.

If MODE = 0, only OBJF needs to be computed;
OBJGRD is ignored.

On exit: MODE may be set to a negative value if the user wishes to terminate the solution to the current problem. If MODE is negative on exit from OBJFUN, then E04UCF will terminate with IFAIL set to MODE.

- 2: N -- INTEGER Input
On entry: the number, n, of variables.

- 3: X(N) -- DOUBLE PRECISION array Input
On entry: the vector x of variables at which the objective function is to be evaluated.

- 4: OBJF -- DOUBLE PRECISION Output
On exit: if MODE = 0 or 2, OBJF must be set to the value of the objective function at x.

- 5: OBJGRD(N) -- DOUBLE PRECISION array Output
On exit: if MODE = 1 or 2, OBJGRD must return the available components of the gradient evaluated at x.

- 6: NSTATE -- INTEGER Input
On entry: if NSTATE = 1 then E04UCF is calling OBJFUN for the first time. This parameter setting allows the user to save computation time if certain data must be read or calculated only once.

- 7: IUSER(*) -- INTEGER array User Workspace

- 8: USER(*) -- DOUBLE PRECISION array User Workspace
OBJFUN is called from E04UCF with the parameters IUSER and USER as supplied to E04UCF. The user is free to use the arrays IUSER and USER to supply information to OBJFUN as an alternative to using COMMON.
OBJFUN must be declared as EXTERNAL in the (sub)program from which E04UCF is called. Parameters denoted as Input must not be changed by this procedure.

- 12: ITER -- INTEGER Output
On exit: the number of iterations performed.

- 13: ISTATE(N+NCLIN+NCNLN) -- INTEGER array Input/Output
On entry: ISTATE need not be initialised if E04UCF is called

with (the default) Cold Start option. The ordering of ISTATE is as follows. The first n elements of ISTATE refer to the upper and lower bounds on the variables, elements $n+1$ through $n+n$ refer to the upper and lower bounds on A , and elements $n+n+1$ through $n+n+n$ refer to the upper and lower bounds on $c(x)$. When a Warm Start option is chosen, the elements of ISTATE corresponding to the bounds and linear constraints define the initial working set for the procedure that finds a feasible point for the linear constraints and bounds. The active set at the conclusion of this procedure and the elements of ISTATE corresponding to nonlinear constraints then define the initial working set for the first QP subproblem. Possible values for ISTATE(j) are:

ISTATE(j) Meaning

- 0 The corresponding constraint is not in the initial QP working set.
- 1 This inequality constraint should be in the working set at its lower bound.
- 2 This inequality constraint should be in the working set at its upper bound.
- 3 This equality constraint should be in the initial working set. This value must not be specified unless $BL(j) = BU(j)$. The values 1,2 or 3 all have the same effect when $BL(j) = BU(j)$.

Note that if E04UCF has been called previously with the same values of N , $NCLIN$ and $NCNLN$, ISTATE already contains satisfactory values. If necessary, E04UCF will override the user's specification of ISTATE so that a poor choice will not cause the algorithm to fail. On exit: with $IFAIL = 0$ or 1, the values in the array ISTATE correspond to the active set of the final QP subproblem, and are a prediction of the status of the constraints at the solution of the problem. Otherwise, ISTATE indicates the composition of the QP working set at the final iterate. The significance of each possible value of ISTATE(j) is as follows:

- 2 This constraint violates its lower bound by more than the appropriate feasibility tolerance (see the optional parameters LinearFeasibility Tolerance and Nonlinear Feasibility Tolerance in

Section 5.1). This value can occur only when no feasible point can be found for a QP subproblem.

- 1 This constraint violates its upper bound by more than the appropriate feasibility tolerance (see the optional parameters Linearear Feasibility Tolerance and Nonlinear Feasibility Tolerance in Section 5.1). This value can occur only when no feasible point can be found for a QP subproblem.
- 0 The constraint is satisfied to within the feasibility tolerance, but is not in the working set.
- 1 This inequality constraint is included in the QP working set at its upper bound.
- 2 This inequality constraint is included in the QP working set at its upper bound.
- 3 This constraint is included in the QP working set as an equality. This value of ISTATE can occur only when $BL(j) = BU(j)$.

- 14: C(*) -- DOUBLE PRECISION array Output
 Note: the dimension of the array C must be at least $\max(1, NCNLN)$.
 On exit: if $NCNLN > 0$, C(i) contains the value of the i th nonlinear constraint function c at the final iterate, for $i=1, 2, \dots, NCNLN$. If $NCNLN = 0$, then the array C is not referenced.
- 15: CJAC(NROWJ,*) -- DOUBLE PRECISION array Input/Output
 Note: the second dimension of the array CJAC must be at least N for $NCNLN > 0$ and 1 otherwise On entry: in general, CJAC need not be initialised before the call to E04UCF. However, if Derivative Level = 3, the user may optionally set the constant elements of CJAC (see parameter NSTATE in the description of CONFUN). Such constant elements need not be re-assigned on subsequent calls to CONFUN. If $NCNLN = 0$, then the array CJAC is not referenced. On exit: if $NCNLN > 0$, CJAC contains the Jacobian matrix of the nonlinear constraint functions at the final iterate, i.e., $CJAC(i, j)$ contains the partial derivative of the i th constraint function with respect to the j th variable, for $i=1, 2, \dots$,

NCNLN; $j = 1, 2, \dots, N$. (See the discussion of parameter CJAC under CONFUN.)

- 16: CLAMDA(N+NCLIN+NCNLN) -- DOUBLE PRECISION array Input/Output
 On entry: CLAMDA need not be initialised if E04UCF is called with the (default) Cold Start option. With the Warm Start option, CLAMDA must contain a multiplier estimate for each nonlinear constraint with a sign that matches the status of the constraint specified by the ISTATE array (as above). The ordering of CLAMDA is as follows; the first n elements contain the multipliers for the bound constraints on the variables, elements $n+1$ through $n+n$ contain the multipliers L for the general linear constraints, and elements $n+n+1$ through $n+n+n$ contain the multipliers L for the nonlinear constraints. If the j th constraint is defined as 'inactive' by the initial value of the ISTATE array, CLAMDA(j) should be zero; if the j th constraint is an inequality active at its lower bound, CLAMDA(j) should be non-negative; if the j th constraint is an inequality active at its upper bound, CLAMDA(j) should be non-positive. On exit: the values of the QP multipliers from the last QP subproblem. CLAMDA(j) should be non-negative if ISTATE(j) = 1 and non-positive if ISTATE(j) = 2.
- 17: OBJF -- DOUBLE PRECISION Output
 On exit: the value of the objective function, $F(x)$, at the final iterate.
- 18: OBJGRD(N) -- DOUBLE PRECISION array Output
 On exit: the gradient (or its finite-difference approximation) of the objective function at the final iterate.
- 19: R(NROWR,N) -- DOUBLE PRECISION array Input/Output
 On entry: R need not be initialised if E04UCF is called with a Cold Start option (the default), and will be taken as the identity. With a Warm Start R must contain the upper-triangular Cholesky factor R of the initial approximation of the Hessian of the Lagrangian function, with the variables in the natural order. Elements not in the upper-triangular part of R are assumed to be zero and need not be assigned. On exit: if Hessian = No, (the default; see Section 5.1), R
- T^{\sim}

contains the upper-triangular Cholesky factor R of $Q^T H Q$, an estimate of the transformed and re-ordered Hessian of the Lagrangian at x (see (6) in Section 3). If Hessian = Yes, R contains the upper-triangular Cholesky factor R of H , the approximate (untransformed) Hessian of the Lagrangian, with the variables in the natural order.

20: $X(N)$ -- DOUBLE PRECISION array Input/Output
 On entry: an initial estimate of the solution. On exit: the final estimate of the solution.

21: $IWORK(LIWORK)$ -- INTEGER array Workspace

22: $LIWORK$ -- INTEGER Input
 On entry:
 the dimension of the array $IWORK$ as declared in the
 (sub)program from which E04UCF is called.
 Constraint: $LIWORK \geq 3 \cdot N + NCLIN + 2 \cdot NCNIN$.

23: $WORK(LWORK)$ -- DOUBLE PRECISION array Workspace

24: $LWORK$ -- INTEGER Input
 On entry:
 the dimension of the array $WORK$ as declared in the
 (sub)program from which E04UCF is called.
 Constraints:
 if $NCLIN = NCNIN = 0$ then
 $LWORK \geq 20 \cdot N$

 if $NCNIN = 0$ and $NCLIN > 0$ then
 2
 $LWORK \geq 2 \cdot N + 20 \cdot N + 11 \cdot NCLIN$

 if $NCNIN > 0$ and $NCLIN \geq 0$ then
 2
 $LWORK \geq 2 \cdot N + N \cdot NCLIN + 20 \cdot N \cdot NCNIN + 20 \cdot N + 11 \cdot NCLIN + 21 \cdot NCNIN$

If Major Print Level > 0 , the required amounts of workspace are output on the current advisory message channel (see X04ABF). As an alternative to computing $LIWORK$ and $LWORK$ from the formulas given above, the user may prefer to obtain appropriate values from the output of a preliminary run with a positive value of Major Print Level and $LIWORK$ and $LWORK$ set to 1. (E04UCF will then terminate with IFAIL = 9.)

25: $IUSER(*)$ -- INTEGER array User Workspace

Note: the dimension of the array IUSER must be at least 1. IUSER is not used by E04UCF, but is passed directly to routines CONFUN and OBJFUN and may be used to pass information to those routines.

26: USER(*) -- DOUBLE PRECISION array User Workspace
 Note: the dimension of the array USER must be at least 1. USER is not used by E04UCF, but is passed directly to routines CONFUN and OBJFUN and may be used to pass information to those routines.

27: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL \neq 0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

E04UCF returns with IFAIL = 0 if the iterates have converged to a point x that satisfies the first-order Kuhn-Tucker conditions to the accuracy requested by the optional parameter Optimality Tolerance (see Section 5.1), i.e., the projected gradient and active constraint residuals are negligible at x .

The user should check whether the following four conditions are satisfied:

- (i) the final value of Norm Gz is significantly less than that at the starting point;
- (ii) during the final major iterations, the values of Step and ItQP are both one;
- (iii) the last few values of both Norm Gz and Norm C become small at a fast linear rate;
- (iv) Cond Hz is small.

If all these conditions hold, x is almost certainly a local minimum of (1). (See Section 9 for a specific example.)

5.1. Optional Input Parameters

Several optional parameters in E04UCF define choices in the behaviour of the routine. In order to reduce the number of formal parameters of E04UCF these optional parameters have associated default values (see Section 5.1.3) that are appropriate for most problems. Therefore the user need only specify those optional parameters whose values are to be different from their default values.

The remainder of this section can be skipped by users who wish to use the default values for all optional parameters. A complete list of optional parameters and their default values is given in Section 5.1.3

5.1.1. Specification of the optional parameters

Optional parameters may be specified by calling one, or both, of E04UDF and E04UEF prior to a call to E04UCF.

E04UDF reads options from an external options file, with Begin and End as the first and last lines respectively and each intermediate line defining a single optional parameter. For example,

```
Begin
  Print Level = 1
End
```

The call

```
CALL E04UDF (IOPTNS, INFORM)
```

can then be used to read the file on unit IOPTNS. INFORM will be zero on successful exit. E04UDF should be consulted for a full description of this method of supplying optional parameters.

E04UEF can be called directly to supply options, one call being necessary for each optional parameter. For example,

```
CALL E04UEF ('Print level = 1')
```

E04UEF should be consulted for a full description of this method of supplying optional parameters.

All optional parameters not specified by the user are set to

their default values. Optional parameters specified by the user are unaltered by E04UCF (unless they define invalid values) and so remain in effect for subsequent calls to E04UCF, unless altered by the user.

5.1.2. Description of the optional parameters

The following list (in alphabetical order) gives the valid options. For each option, we give the keyword, any essential optional qualifiers, the default value, and the definition. The minimum valid abbreviation of each keyword is underlined. If no characters of an optional qualifier are underlined, the qualifier may be omitted. The letter a denotes a phrase (character string) that qualifies an option. The letters i and r denote INTEGER and DOUBLE PRECISION values required with certain options. The number (epsilon) is a generic notation for machine precision (see X02AJF(*)), and (epsilon) denotes the relative precision of the R objective function (the optional parameter Function Precision see below).

Central Difference Interval r Default values are computed

If the algorithm switches to central differences because the forward-difference approximation is not sufficiently accurate, the value of r is used as the difference interval for every component of x. The use of finite-differences is discussed further below under the optional parameter Difference Interval.

Cold Start Default = Cold Start

Warm Start

(AXIOM parameter STA, warm start when .TRUE.)

This option controls the specification of the initial working set in both the procedure for finding a feasible point for the linear constraints and bounds, and in the first QP subproblem thereafter. With a Cold Start, the first working set is chosen by E04UCF based on the values of the variables and constraints at the initial point. Broadly speaking, the initial working set will include equality constraints and bounds or inequality constraints that violate or 'nearly' satisfy their bounds (within Crash Tolerance; see below). With a Warm Start, the user must set the ISTATE array and define CLAMDA and R as discussed in Section 5. ISTATE values associated with bounds and linear constraints

determine the initial working set of the procedure to find a feasible point with respect to the bounds and linear constraints. ISTATE values associated with nonlinear constraints determine the initial working set of the first QP subproblem after such a feasible point has been found. E04UCF will override the user's specification of ISTATE if necessary, so that a poor choice of the working set will not cause a fatal error. A warm start will be advantageous if a good estimate of the initial working set is available - for example, when E04UCF is called repeatedly to solve related problems.

Crash Tolerance r Default = 0.01

(AXIOM parameter CRA)

This value is used in conjunction with the optional parameter Cold Start (the default value). When making a cold start, the QP algorithm in E04UCF must select an initial working set. When $r \geq 0$, the initial working set will include (if possible) bounds or general inequality constraints that lie within r of their bounds.

T

In particular, a constraint of the form $a_j x_j \geq 1$ will be included

T

in the initial working set if $|a_j x_j - 1| \leq r(1 + |1|)$. If $r < 0$ or $r > 1$,
j
the default value is used.

Defaults

This special keyword may be used to reset the default values following a call to E04UCF.

Derivative Level i Default = 3

(AXIOM parameter DER)

This parameter indicates which derivatives are provided by the user in subroutines OBJFUN and CONFUN. The possible choices for i are the following.

- | | |
|---|--|
| i | Meaning |
| 3 | All objective and constraint gradients are provided by the user. |

- 2 All of the Jacobian is provided, but some components of the objective gradient are not specified by the user.
- 1 All elements of the objective gradient are known, but some elements of the Jacobian matrix are not specified by the user.
- 0 Some elements of both the objective gradient and the Jacobian matrix are not specified by the user.

The value $i=3$ should be used whenever possible, since E04UCF is more reliable and will usually be more efficient when all derivatives are exact.

If $i=0$ or 2 , E04UCF will estimate the unspecified components of the objective gradient, using finite differences. The computation of finite-difference approximations usually increases the total run-time, since a call to OBJFUN is required for each unspecified element. Furthermore, less accuracy can be attained in the solution (see Chapter 8 of Gill et al [10], for a discussion of limiting accuracy).

If $i=0$ or 1 , E04UCF will approximate unspecified elements of the Jacobian. One call to CONFUN is needed for each variable for which partial derivatives are not available. For example, if the Jacobian has the form

```
( * * * * )
( * ? ? * )
( * * ? * )
( * * * * )
```

where '*' indicates an element provided by the user and '?' indicates an unspecified element, E04UCF will call CONFUN twice: once to estimate the missing element in column 2, and again to estimate the two missing elements in column 3. (Since columns 1 and 4 are known, they require no calls to CONFUN.)

At times, central differences are used rather than forward differences, in which case twice as many calls to OBJFUN and CONFUN are needed. (The switch to central differences is not under the user's control.)

Difference Interval r Default values are computed

(AXIOM parameter DIF)

This option defines an interval used to estimate gradients by finite differences in the following circumstances:

- (a) For verifying the objective and/or constraint gradients (see the description of Verify, below).
- (b) For estimating unspecified elements of the objective gradient of the Jacobian matrix.

In general, a derivative with respect to the j th variable is approximated using the interval $(\delta)_j$, where $(\delta)_j = r(1 + |x_j|)$

with x the first point feasible with respect to the bounds and linear constraints. If the functions are well scaled, the resulting derivative approximation should be accurate to $O(r)$.

See Gill et al [10] for a discussion of the accuracy in finite-difference approximations.

If a difference interval is not specified by the user, a finite-difference interval will be computed automatically for each variable by a procedure that requires up to six calls of CONFUN and OBJFUN for each component. This option is recommended if the function is badly scaled or the user wishes to have E04UCF determine constant elements in the objective and constraint gradients (see the descriptions of CONFUN and OBJFUN in Section 5).

Feasibility Tolerance r Default = $\sqrt{(\epsilon)}$

(AXIOM parameter FEA)

The scalar r defines the maximum acceptable absolute violations in linear and nonlinear constraints at a 'feasible' point; i.e., a constraint is considered satisfied if its violation does not exceed r . If $r < (\epsilon)$ or $r \geq 1$, the default value is used. Using this keyword sets both optional parameters Linear Feasibility Tolerance and Nonlinear Feasibility Tolerance to r , if $(\epsilon) \leq r < 1$. (Additional details are given below under the descriptions of these parameters.)

Function Precision r Default = (epsilon)

(AXIOM parameter FUN)

This parameter defines (epsilon), which is intended to be a
 R
 measure of the accuracy with which the problem functions f and c
 can be computed. If $r < (\text{epsilon})$ or $r \geq 1$, the default value is
 used. The value of (epsilon) should reflect the relative
 R
 precision of $1 + |F(x)|$; i.e., (epsilon) acts as a relative
 R
 precision when $|F|$ is large, and as an absolute precision when
 $|F|$ is small. For example, if $F(x)$ is typically of order 1000 and
 the first six significant digits are known to be correct, an
 appropriate value for (epsilon) would be $1.0E-6$. In contrast, if
 R
 $F(x)$ is typically of order 10^{-4} and the first six significant
 digits are known to be correct, an appropriate value for
 (epsilon) would be $1.0E-10$. The choice of (epsilon) can be
 R R
 quite complicated for badly scaled problems; see Chapter 8 of
 Gill et al [10] for a discussion of scaling techniques. The
 default value is appropriate for most simple functions that are
 computed with full accuracy. However, when the accuracy of the
 computed function values is known to be significantly worse than
 full precision, the value of (epsilon) should be large enough so
 R
 that E04UCF will not attempt to distinguish between function
 values that differ by less than the error inherent in the
 calculation.

Hessian No Default = No

Hessian Yes

(No AXIOM parameter - fixed as Yes)

This option controls the contents of the upper-triangular matrix
 R (see Section 5). E04UCF works exclusively with the transformed
 and re-ordered Hessian H (6), and hence extra computation is

Q
 required to form the Hessian itself. If Hessian = No, R contains
 the Cholesky factor of the transformed and re-ordered Hessian. If
 Hessian = Yes the Cholesky factor of the approximate Hessian

itself is formed and stored in R. The user should select Hessian = Yes if a warm start will be used for the next call to E04UCF.

10

Infinite Bound Size r Default = 10

(AXIOM parameter INFB)

If $r > 0$, r defines the 'infinite' bound BIGBND in the definition of the problem constraints. Any upper bound greater than or equal to BIGBND will be regarded as plus infinity (and similarly for a lower bound less than or equal to $-BIGBND$). If $r \leq 0$, the default value is used.

10

Infinite Step Size r Default = $\max(BIGBND, 10)$

(AXIOM parameter INFS)

If $r > 0$, r specifies the magnitude of the change in variables that is treated as a step to an unbounded solution. If the change in x during an iteration would exceed the value of Infinite Step Size, the objective function is considered to be unbounded below in the feasible region. If $r \leq 0$, the default value is used.

Iteration limit i Default = $\max(50, 3(n_L + n_N) + 10n_N)$

See Major Iteration Limit below.

Linear Feasibility Tolerance r Default = $\sqrt{(\epsilon)}$

1

(AXIOM parameter LINF)

Nonlinear Feasibility Tolerance r Default = $\sqrt{(\epsilon)}$ if

2

(AXIOM parameter NONF)

0.33

Derivative Level ≥ 2 and (ϵ) otherwise

The scalars r_1 and r_2 define the maximum acceptable absolute

1 2

violations in linear and nonlinear constraints at a 'feasible' point; i.e., a linear constraint is considered satisfied if its violation does not exceed r_1 , and similarly for a nonlinear constraint and r_2 . If $r_i < (\text{epsilon})$ or $r_i \geq 1$, the default value is used, for $i=1,2$.

On entry to E04UCF, an iterative procedure is executed in order to find a point that satisfies the linear constraint and bounds on the variables to within the tolerance r_1 . All subsequent iterates will satisfy the linear constraints to within the same tolerance (unless r_1 is comparable to the finite-difference interval).

For nonlinear constraints, the feasibility tolerance r_2 defines the largest constraint violation that is acceptable at an optimal point. Since nonlinear constraints are generally not satisfied until the final iterate, the value of Nonlinear Feasibility Tolerance acts as a partial termination criterion for the iterative sequence generated by E04UCF (see the discussion of Optimality Tolerance).

These tolerances should reflect the precision of the corresponding constraints. For example, if the variables and the coefficients in the linear constraints are of order unity, and the latter are correct to about 6 decimal digits, it would be appropriate to specify r_1 as 10^{-6} .

Linesearch Tolerance r Default = 0.9

(AXIOM parameter LINT)

The value r ($0 \leq r < 1$) controls the accuracy with which the step (α) taken during each iteration approximates a minimum of the merit function along the search direction (the smaller the value of r , the more accurate the linesearch). The default value $r=0.9$ requests an inaccurate search, and is appropriate for most problems, particularly those with any nonlinear constraints.

If there are no nonlinear constraints, a more accurate search may be appropriate when it is desirable to reduce the number of major iterations - for example, if the objective function is cheap to evaluate, or if a substantial number of gradients are unspecified.

List Default = List

Nolist

(AXIOM parameter LIST)

Normally each optional parameter specification is printed as it is supplied. Nolist may be used to suppress the printing and List may be used to restore printing.

Major Iteration Limit i Default = $\max(50, 3(n+n_L)+10n_N)$

Iteration Limit

Iters

Itns

(AXIOM parameter MAJI)

The value of i specifies the maximum number of major iterations allowed before termination. Setting i=0 and Major Print Level> 0 means that the workspace needed will be computed and printed, but no iterations will be performed.

Major Print level i Default = 10

Print Level

(AXIOM parameter MAJP)

The value of i controls the amount of printout produced by the major iterations of E04UCF. (See also Minor Print level below.) The levels of printing are indicated below.

i	Output
0	No output.

- 1 The final solution only.
- 5 One line for each major iteration (no printout of the final solution).
- ≥ 10 The final solution and one line of output for each iteration.
- ≥ 20 At each major iteration, the objective function, the Euclidean norm of the nonlinear constraint violations, the values of the nonlinear constraints (the vector c), the values of the linear constraints (the vector Ax),

L

and the current values of the variables (the vector x).
- ≥ 30 At each major iteration, the diagonal elements of the matrix T associated with the TQ factorization (5) of the QP working set, and the diagonal elements of R , the triangular factor of the transformed and re-ordered Hessian (6).

Minor Iteration Limit i Default = $\max(50, 3(n + n_L + n_N))$

(AXIOM parameter MINI)

The value of i specifies the maximum number of iterations for the optimality phase of each QP subproblem.

Minor Print Level i Default = 0

(AXIOM parameter MINP)

The value of i controls the amount of printout produced by the minor iterations of E04UCF, i.e., the iterations of the quadratic programming algorithm. (See also Major Print Level, above.) The following levels of printing are available.

- i Output
- 0 No output.
- 1 The final QP solution.
- 5 One line of output for each minor iteration (no printout of the final QP solution).

- >=10 The final QP solution and one brief line of output for each minor iteration.
- >=20 At each minor iteration, the current estimates of the QP multipliers, the current estimate of the QP search direction, the QP constraint values, and the status of each QP constraint.
- >=30 At each minor iteration, the diagonal elements of the matrix T associated with the TQ factorization (5) of the QP working set, and the diagonal elements of the Cholesky factor R of the transformed Hessian (6).

Nonlinear Feasibility Tolerance r Default = $\sqrt{\epsilon}$

See Linear Feasibility Tolerance, above.

Optimality Tolerance r Default = 0.8ϵ

(AXIOM parameter OPT)

The parameter r ($\epsilon < r < 1$) specifies the accuracy to which the user wishes the final iterate to approximate a solution of the problem. Broadly speaking, r indicates the number of correct figures desired in the objective function at the solution. For example, if r is 10 and E04UCF terminates successfully, the final value of F should have approximately six correct figures. If $r < \epsilon$ or $r \geq 1$ the default value is used.

E04UCF will terminate successfully if the iterative sequence of x-values is judged to have converged and the final point satisfies the first-order Kuhn-Tucker conditions (see Section 3). The sequence of iterates is considered to have converged at x if

$$(\alpha) \|p\| \leq \sqrt{r(1+\|x\|)}, \quad (8a)$$

where p is the search direction and (alpha) the step length from (3). An iterate is considered to satisfy the first-order conditions for a minimum if

$$\|Z_{FR}^T g_{FR}\| \leq \sqrt{r(1+\max(1, \|F(x)\|, \|g_{FR}\|))} \quad (8b)$$

and

$$|res_j| \leq ftol \text{ for all } j, \quad (8c)$$

where $Z_{FR}^T g_{FR}$ is the projected gradient (see Section 3), g_{FR} is the gradient of $F(x)$ with respect to the free variables, res_j is the violation of the j th active nonlinear constraint, and $ftol$ is the Nonlinear Feasibility Tolerance.

Step Limit r Default = 2.0

(AXIOM parameter STE)

If $r > 0$, r specifies the maximum change in variables at the first step of the linesearch. In some cases, such as $F(x) = a e^{bx}$ or $F(x) = ax^b$, even a moderate change in the components of x can lead to floating-point overflow. The parameter r is therefore used to encourage evaluation of the problem functions at meaningful points. Given any major iterate x , the first point \tilde{x} at which F and c are evaluated during the linesearch is restricted so that

$$\|x - \tilde{x}\|_2 \leq r(1 + \|x\|_2).$$

The linesearch may go on and evaluate F and c at points further from x if this will result in a lower value of the merit function. In this case, the character L is printed at the end of the optional line of printed output, (see Section 5.2). If L is printed for most of the iterations, r should be set to a larger value.

Wherever possible, upper and lower bounds on x should be used to prevent evaluation of nonlinear functions at wild values. The

default value Step Limit = 2.0 should not affect progress on well-behaved functions, but values 0.1 or 0.01 may be helpful when rapidly varying functions are present. If a small value of Step Limit is selected, a good starting point may be required. An important application is to the class of nonlinear least-squares problems. If $r \leq 0$, the default value is used.

Start Objective Check At Variable k Default = 1

(AXIOM parameter STAO)

Start Constraint Check At Variable k Default = 1

(AXIOM parameter STAC)

Stop Objective Check At Variable l Default = n

(AXIOM parameter STOO)

Stop Constraint Check At Variable l Default = n

(AXIOM parameter STOC)

These keywords take effect only if Verify Level > 0 (see below). They may be used to control the verification of gradient elements computed by subroutines OBJFUN and CONFUN. For example, if the first 30 components of the objective gradient appeared to be correct in an earlier run, so that only component 31 remains questionable, it is reasonable to specify Start Objective Check At Variable 31. If the first 30 variables appear linearly in the objective, so that the corresponding gradient elements are constant, the above choice would also be appropriate.

Verify Level i Default = 0

Verify No

Verify Level - 1

Verify Level 0

Verify Objective Gradients

Verify Level 1

Verify Constraint Gradients

Verify Level 2

Verify

Verify Yes

Verify Gradients

Verify Level 3

(AXIOM parameter VE)

These keywords refer to finite-difference checks on the gradient elements computed by the user-provided subroutines OBJFUN and CONFUN. (Unspecified gradient components are not checked.) It is possible to specify Verify Levels 0-3 in several ways, as indicated above. For example, the nonlinear objective gradient (if any) will be verified if either Verify Objective Gradients or Verify Level 1 is specified. Similarly, the objective and the constraint gradients will be verified if Verify Yes or Verify Level 3 or Verify is specified.

If $0 \leq i \leq 3$, gradients will be verified at the first point that satisfies the linear constraints and bounds. If $i=0$, only a 'cheap' test will be performed, requiring one call to OBJFUN and one call to CONFUN. If $1 \leq i \leq 3$, a more reliable (but more expensive) check will be made on individual gradient components, within the ranges specified by the Start and Stop keywords described above. A result of the form OK or BAD? is printed by E04UCF to indicate whether or not each component appears to be correct.

If $10 \leq i \leq 13$, the action is the same as for $i = 10$, except that it will take place at the user-specified initial value of x .

We suggest that Verify Level 3 be specified whenever a new function routine is being developed.

5.1.3. Optional parameter checklist and default values

For easy reference, the following list shows all the valid keywords and their default values. The symbol (epsilon) represents the machine precision (see X02AJF(*)).

Optional Parameters	Default Values
---------------------	----------------

Central difference interval	Computed automatically
Cold/Warm start	Cold start
Crash tolerance	0.01
Defaults	
Derivative level	3
Difference interval	Computed automatically
Feasibility tolerance	$\frac{\text{-----}}{\sqrt{(\text{epsilon})}}$
Function precision	$\frac{0.9}{(\text{epsilon})}$
Hessian	No
Infinite bound size	$\frac{10}{10}$
Infinite step size	$\frac{10}{10}$
Linear feasibility tolerance	$\frac{\text{-----}}{\sqrt{(\text{epsilon})}}$
Linesearch tolerance	0.9
List/Nolist	List
Major iteration limit	$\max(50, 3(\frac{n+n}{L}) + 10\frac{n}{N})$
Major print level	10
Minor iteration limit	$\max(50, 3(\frac{n+n}{L} + \frac{n}{N}))$

Minor print level	0
Nonlinear feasibility tolerance	$\frac{\sqrt{(\text{epsilon})}}{0.33} \text{ if Derivative Level } \geq 2$ otherwise (epsilon)
Optimality tolerance	$\frac{0.8}{R} (\text{epsilon})$
Step limit	2.0
Start objective check	1
Start constraint check	1
Stop objective check	n
Stop constraint check	n
Verify level	0

5.2. Description of Printed Output

The level of printed output from E04UCF is controlled by the user (see the description of Major Print Level and Minor Print Level in Section 5.1). If Minor Print Level > 0, output is obtained from the subroutines that solve the QP subproblem. For a detailed description of this information the reader should refer to E04NCF(*).

When Major Print Level ≥ 5 , the following line of output is produced at every major iteration of E04UCF. In all cases, the values of the quantities printed are those in effect on completion of the given iteration.

Itn is the iteration count.

ItQP is the sum of the iterations required by the feasibility and optimality phases of the QP subproblem. Generally, ItQP will be 1 in the later iterations, since theoretical analysis predicts that the correct active set will be identified near the solution (see Section 3).

Note that ItQP may be greater than the Minor Iteration Limit if some iterations are required for the feasibility phase.

Step	is the step (alpha) taken along the computed search direction. On reasonably well-behaved problems, the unit step will be taken as the solution is approached.
Nfun	is the cumulative number of evaluations of the objective function needed for the linesearch. Evaluations needed for the estimation of the gradients by finite differences are not included. Nfun is printed as a guide to the amount of work required for the linesearch.
Merit	is the value of the augmented Lagrangian merit function (12) at the current iterate. This function will decrease at each iteration unless it was necessary to increase the penalty parameters (see Section 8.2). As the solution is approached, Merit will converge to the value of the objective function at the solution.

If the QP subproblem does not have a feasible point (signified by I at the end of the current output line), the merit function is a large multiple of the constraint violations, weighted by the penalty parameters. During a sequence of major iterations with infeasible subproblems, the sequence of Merit values will decrease monotonically until either a feasible subproblem is obtained or E04UCF terminates with IFAIL = 3 (no feasible point could be found for the nonlinear constraints).

If no nonlinear constraints are present (i.e., NCNLN = 0), this entry contains Objective, the value of the objective function $F(x)$. The objective function will decrease monotonically to its optimal value when there are no nonlinear constraints.

Bnd	is the number of simple bound constraints in the predicted active set.
-----	--

Lin	is the number of general linear constraints in the predicted active set.
Nln	is the number of nonlinear constraints in the predicted active set (not printed if NCNLN is zero).
Nz	is the number of columns of Z (see Section 8.1). The value of Nz is the number of variables minus the number of constraints in the predicted active set; i.e., $Nz = n - (Bnd + Lin + Nln)$.
Norm Gf	is the Euclidean norm of g_{FR} , the gradient of the objective function with respect to the free variables, i.e., variables not currently held at a bound.
Norm Gz	is $\ Z^T g_{FR}\ $, the Euclidean norm of the projected gradient (see Section 8.1). Norm Gz will be approximately zero in the neighbourhood of a solution.
Cond H	is a lower bound on the condition number of the Hessian approximation H.
Cond Hz	is a lower bound on the condition number of the projected Hessian approximation H_z ($H_z = Z^T H Z = R^T R$; see (6) and (12) in Sections 3 and 8.1). The larger this number, the more difficult the problem.
Cond T	is a lower bound on the condition number of the matrix of predicted active constraints.
Norm C	is the Euclidean norm of the residuals of constraints that are violated or in the predicted active set (not printed if NCNLN is zero). Norm C will be approximately zero in the neighbourhood of a solution.

Penalty	is the Euclidean norm of the vector of penalty parameters used in the augmented Lagrangian merit function (not printed if NCNLN is zero).
Conv	<p>is a three-letter indication of the status of the three convergence tests (8a)-(8c) defined in the description of the optional parameter Optimality Tolerance in Section 5.1 Each letter is T if the test is satisfied, and F otherwise. The three tests indicate whether:</p> <ul style="list-style-type: none"> (a) the sequence of iterates has converged; (b) the projected gradient (Norm Gz) is sufficiently small; and (c) the norm of the residuals of constraints in the predicted active set (Norm C) is small enough. <p>If any of these indicators is F when E04UCF terminates with IFAIL = 0, the user should check the solution carefully.</p>
M	is printed if the Quasi-Newton update was modified to ensure that the Hessian approximation is positive-definite (see Section 8.3).
I	is printed if the QP subproblem has no feasible point.
C	is printed if central differences were used to compute the unspecified objective and constraint gradients. If the value of Step is zero, the switch to central differences was made because no lower point could be found in the linesearch. (In this case, the QP subproblem is resolved with the central-difference gradient and Jacobian.) If the value of Step is non-zero, central differences were computed because Norm Gz and Norm C imply that x is close to a Kuhn-Tucker point.
L	is printed if the linesearch has produced a relative change in x greater than the value defined by the optional parameter Step Limit. If this output occurs frequently during later iterations of the run, Step Limit should be set to a larger value.

R is printed if the approximate Hessian has been refactorized. If the diagonal condition estimator of R indicates that the approximate Hessian is badly conditioned, the approximate Hessian is refactorized using column interchanges. If necessary, R is modified so that its diagonal condition estimator is bounded.

When Major Print Level = 1 or Major Print Level ≥ 10 , the summary printout at the end of execution of E04UCF includes a listing of the status of every variable and constraint. Note that default names are assigned to all variables and constraints.

The following describes the printout for each variable.

Varbl	gives the name (V) and index $j=1,2,\dots,n$ of the variable.
State	gives the state of the variable in the predicted active set (FR if neither bound is in the active set, EQ if a fixed variable, LL if on its lower bound, UL if on its upper bound). If the variable is predicted to lie outside its upper or lower bound by more than the feasibility tolerance, State will be ++ or -- respectively. (The latter situation can occur only when there is no feasible point for the bounds and linear constraints.)
Value	is the value of the variable at the final iteration.
Lower bound	is the lower bound specified for the variable. (None indicates that $BL(j) \leq -BIGBND$.)
Upper bound	is the upper bound specified for the variable. (None indicates that $BL(j) \geq BIGBND$.)
Lagr Mult	is the value of the Lagrange-multiplier for the associated bound constraint. This will be zero if State is FR. If x is optimal, the multiplier should be non-negative if State is LL, and non-positive if State is UL.
Residual	is the difference between the variable Value and the nearer of its bounds $BL(j)$ and $BU(j)$.

The printout for general constraints is the same as for variables, except for the following:

L Con is the name (L) and index i , for $i = 1, 2, \dots, \text{NCLIN}$ of a linear constraint.

N Con is the name (N) and index i , for $i = 1, 2, \dots, \text{NCNLN}$ of a nonlinear constraint.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

The input data for E04UCF should always be checked (even if E04UCF terminates with IFAIL=0).

Note that when Print Level > 0, a short description of IFAIL is printed.

Errors and diagnostics indicated by IFAIL, together with some recommendations for recovery are indicated below.

IFAIL= 1

The final iterate x satisfies the first-order Kuhn-Tucker conditions to the accuracy requested, but the sequence of iterates has not yet converged. E04UCF was terminated because no further improvement could be made in the merit function.

This value of IFAIL may occur in several circumstances. The most common situation is that the user asks for a solution with accuracy that is not attainable with the given precision of the problem (as specified by Function Precision see Section 5). This condition will also occur if, by chance, an iterate is an 'exact' Kuhn-Tucker point, but the change in the variables was significant at the previous iteration. (This situation often happens when minimizing very simple functions, such as quadratics.)

If the four conditions listed in Section 5 for IFAIL = 0 are satisfied, x is likely to be a solution of (1) even if IFAIL = 1.

IFAIL= 2

E04UCF has terminated without finding a feasible point for the linear constraints and bounds, which means that no feasible point exists for the given value of Linear Feasibility Tolerance (see Section 5.1). The user should check that there are no constraint redundancies. If the data for the constraints are accurate only to an absolute precision (σ), the user should ensure that the value of the optional parameter Linear Feasibility Tolerance is greater than (σ). For example, if all elements of A are of order unity and are accurate to only three decimal

-3

places, Linear Feasibility Tolerance should be at least 10 .

IFAIL= 3

No feasible point could be found for the nonlinear constraints. The problem may have no feasible solution. This means that there has been a sequence of QP subproblems for which no feasible point could be found (indicated by I at the end of each terse line of output). This behaviour will occur if there is no feasible point for the nonlinear constraints. (However, there is no general test that can determine whether a feasible point exists for a set of nonlinear constraints.) If the infeasible subproblems occur from the very first major iteration, it is highly likely that no feasible point exists. If infeasibilities occur when earlier subproblems have been feasible, small constraint inconsistencies may be present. The user should check the validity of constraints with negative values of ISTATE. If the user is convinced that a feasible point does exist, E04UCF should be restarted at a different starting point.

IFAIL= 4

The limiting number of iterations (determined by the optional parameter Major Iteration Limit see Section 5.1) has been reached.

If the algorithm appears to be making progress, Major Iteration Limit may be too small. If so, increase its value and rerun E04UCF (possibly using the Warm Start option). If the algorithm seems to be 'bogged down', the user should check for incorrect gradients or ill-conditioning as described below under IFAIL = 6.

Note that ill-conditioning in the working set is sometimes

resolved automatically by the algorithm, in which case performing additional iterations may be helpful. However, ill-conditioning in the Hessian approximation tends to persist once it has begun, so that allowing additional iterations without altering R is usually inadvisable. If the quasi-Newton update of the Hessian approximation was modified during the latter iterations (i.e., an M occurs at the end of each terse line), it may be worthwhile to try a warm start at the final point as suggested above.

IFAIL= 6

x does not satisfy the first-order Kuhn-Tucker conditions, and no improved point for the merit function could be found during the final line search.

A sufficient decrease in the merit function could not be attained during the final line search. This sometimes occurs because an overly stringent accuracy has been requested, i.e., Optimality Tolerance is too small. In this case the user should apply the four tests described under IFAIL = 0 above to determine whether or not the final solution is acceptable (see Gill et al [10], for a discussion of the attainable accuracy).

If many iterations have occurred in which essentially no progress has been made and E04UCF has failed completely to move from the initial point then subroutines OBJFUN or CONFUN may be incorrect. The user should refer to comments below under IFAIL = 7 and check the gradients using the Verify parameter. Unfortunately, there may be small errors in the objective and constraint gradients that cannot be detected by the verification process. Finite-difference approximations to first derivatives are catastrophically affected by even small inaccuracies. An indication of this situation is a dramatic alteration in the iterates if the finite-difference interval is altered. One might also suspect this type of error if a switch is made to central differences even when Norm Gz and Norm C are large.

Another possibility is that the search direction has become inaccurate because of ill-conditioning in the Hessian approximation or the matrix of constraints in the working set; either form of ill-conditioning tends to be reflected in large values of ItQP (the number of iterations required to solve each QP subproblem).

If the condition estimate of the projected Hessian (Cond Hz) is extremely large, it may be worthwhile to rerun E04UCF from the final point with the Warm Start option. In this situation, ISTATE should be left unaltered and R should be reset to the identity matrix.

If the matrix of constraints in the working set is ill-conditioned (i.e., Cond T is extremely large), it may be helpful to run E04UCF with a relaxed value of the Feasibility Tolerance (Constraint dependencies are often indicated by wide variations in size in the diagonal elements of the matrix T, whose diagonals will be printed for Major Print Level ≥ 30).

IFAIL= 7

The user-provided derivatives of the objective function and/or nonlinear constraints appear to be incorrect.

Large errors were found in the derivatives of the objective function and/or nonlinear constraints. This value of IFAIL will occur if the verification process indicated that at least one gradient or Jacobian component had no correct figures. The user should refer to the printed output to determine which elements are suspected to be in error.

As a first-step, the user should check that the code for the objective and constraint values is correct - for example, by computing the function at a point where the correct value is known. However, care should be taken that the chosen point fully tests the evaluation of the function. It is remarkable how often the values $x=0$ or $x=1$ are used to test function evaluation procedures, and how often the special properties of these numbers make the test meaningless.

Special care should be used in this test if computation of the objective function involves subsidiary data communicated in COMMON storage. Although the first evaluation of the function may be correct, subsequent calculations may be in error because some of the subsidiary data has accidentally been overwritten.

Errors in programming the function may be quite subtle in that the function value is 'almost' correct. For example, the function may not be accurate to full precision because of the inaccurate calculation of a subsidiary quantity, or the limited accuracy of data upon which the function

depends. A common error on machines where numerical calculations are usually performed in double precision is to include even one single-precision constant in the calculation of the function; since some compilers do not convert such constants to double precision, half the correct figures may be lost by such a seemingly trivial error.

IFAIL= 9

An input parameter is invalid. The user should refer to the printed output to determine which parameter must be redefined.

IFAILOverflow

If the printed output before the overflow error contains a warning about serious ill-conditioning in the working set when adding the j th constraint, it may be possible to avoid the difficulty by increasing the magnitude of the optional parameter Linear Feasibility Tolerance or Nonlinear Feasibility Tolerance, and rerunning the program. If the message recurs even after this change, the offending linearly dependent constraint (with index ' j ') must be removed from the problem. If overflow occurs in one of the user-supplied routines (e.g. if the nonlinear functions involve exponentials or singularities), it may help to specify tighter bounds for some of the variables (i.e., reduce the gap between appropriate l_j and u_j).

$j \qquad j$

7. Accuracy

If IFAIL = 0 on exit then the vector returned in the array X is an estimate of the solution to an accuracy of approximately Feasibility Tolerance (see Section 5.1), whose default value is

0.8

(epsilon) , where (epsilon) is the machine precision (see X02AJF(*)).

8. Further Comments

In this section we give some further details of the method used by E04UCF.

8.1. Solution of the Quadratic Programming Subproblem

The search direction p is obtained by solving (4) using the method of E04NCF(*) (Gill et al [8]), which was specifically

designed to be used within an SQP algorithm for nonlinear programming.

The method of E04UCF is a two-phase (primal) quadratic programming method. The two phases of the method are: finding an initial feasible point by minimizing the sum of infeasibilities (the feasibility phase), and minimizing the quadratic objective function within the feasible region (the optimality phase). The computations in both phases are performed by the same subroutines. The two-phase nature of the algorithm is reflected by changing the function being minimized from the sum of infeasibilities to the quadratic objective function.

In general, a quadratic program must be solved by iteration. Let p denote the current estimate of the solution of (4); the new

iterate \bar{p} is defined by

$$\bar{p} = p + (\sigma)d, \quad (9)$$

where, as in (3), (σ) is a non-negative step length and d is a search direction.

At the beginning of each iteration of E04UCF, a working set is defined of constraints (general and bound) that are satisfied exactly. The vector d is then constructed so that the values of constraints in the working set remain unaltered for any move along d . For a bound constraint in the working set, this property is achieved by setting the corresponding component of d to zero, i.e., by fixing the variable at its bound. As before, the subscripts 'FX' and 'FR' denote selection of the components associated with the fixed and free variables.

Let C denote the sub-matrix of rows of

$$\begin{pmatrix} A \\ L \\ A \\ N \end{pmatrix}$$

corresponding to general constraints in the working set. The general constraints in the working set will remain unaltered if

$$C \begin{pmatrix} d \\ FR \end{pmatrix} = 0, \quad (10)$$

which is equivalent to defining d_{FR} as

$$d_{FR} = Z d_z \quad (11)$$

for some vector d_z , where Z is the matrix associated with the TQ factorization (5) of C_{FR} .

The definition of d_{FR} in (11) depends on whether the current p is feasible. If not, d_z is zero except for a component (γ) in the j th position, where j and (γ) are chosen so that the sum of infeasibilities is decreasing along d . (For further details, see Gill et al [8].) In the feasible case, d_z satisfies the equations

$$R_{zz}^T d_z = -Z_{FR}^T q_{FR}, \quad (12)$$

where R_z is the Cholesky factor of $Z^T H_z Z$ and q_{FR} is the gradient

of the quadratic objective function ($q = g + H p$). (The vector $Z_{FR}^T q_{FR}$ is the projected gradient of the QP.) With (12), $P + d$ is the minimizer of the quadratic objective function subject to treating the constraints in the working set as equalities.

If the QP projected gradient is zero, the current point is a constrained stationary point in the subspace defined by the working set. During the feasibility phase, the projected gradient will usually be zero only at a vertex (although it may vanish at non-vertices in the presence of constraint dependencies). During the optimality phase, a zero projected gradient implies that p minimizes the quadratic objective function when the constraints in the working set are treated as equalities. In either case, Lagrange multipliers are computed. Given a positive constant (δ) of the order of the machine precision, the Lagrange

multiplier $(\mu)_j$ corresponding to an inequality constraint in the working set at its upper bound is said to be optimal if $(\mu)_j \leq (\delta)$ when the j th constraint is at its upper bound, or if $(\mu)_j \geq -(\delta)$ when the associated constraint is at its lower bound. If any multiplier is non-optimal, the current objective function (either the true objective or the sum of infeasibilities) can be reduced by deleting the corresponding constraint from the working set.

If optimal multipliers occur during the feasibility phase and the sum of infeasibilities is non-zero, no feasible point exists. The QP algorithm will then continue iterating to determine the minimum sum of infeasibilities. At this point, the Lagrange multiplier $(\mu)_j$ will satisfy $-(1+(\delta)) \leq (\mu)_j \leq (\delta)$ for an inequality constraint at its upper bound, and $-(\delta) \leq (\mu)_j \leq 1+(\delta)$ for an inequality at its lower bound. The Lagrange multiplier for an equality constraint will satisfy $|(\mu)_j| \leq 1+(\delta)$.

The choice of step length (σ) in the QP iteration (9) is based on remaining feasible with respect to the satisfied constraints. During the optimality phase, if $p+d$ is feasible, (σ) will be taken as unity. (In this case, the projected gradient at p will be zero.) Otherwise, (σ) is set to (σ) , the step to the 'nearest' constraint, which is added to the working set at the next iteration.

Each change in the working set leads to a simple change to C :
if the status of a general constraint changes, a row of C is altered; if a bound constraint enters or leaves the working set, a column of C changes. Explicit representations are recurred of the matrices T , Q and R , and of the vectors $Q^T q$ and $Q^T g$.

8.2. The Merit Function

After computing the search direction as described in Section 3, each major iteration proceeds by determining a step length (α) in (3) that produces a 'sufficient decrease' in the augmented Lagrangian merit function

$$L(x, (\lambda), s) = F(x) - \sum_i (\lambda_i (c_i(x) - s_i)) + \frac{1}{2} \sum_i (\rho_i (c_i(x) - s_i)^2), \quad (13)$$

where x , (λ) and s vary during the linsearch. The summation terms in (13) involve only the nonlinear constraints. The vector (λ) is an estimate of the Lagrange multipliers for the nonlinear constraints of (1). The non-negative slack variables $\{s_i\}$ allow nonlinear inequality constraints to be treated without

introducing discontinuities. The solution of the QP subproblem (4) provides a vector triple that serves as a direction of search for the three sets of variables. The non-negative vector (ρ) of penalty parameters is initialised to zero at the beginning of the first major iteration. Thereafter, selected components are increased whenever necessary to ensure descent for the merit function. Thus, the sequence of norms of (ρ) (the printed quantity Penalty, see Section 5.2) is generally non-decreasing, although each (ρ_i) may be reduced a limited number of times.

The merit function (13) and its global convergence properties are described in Gill et al [9].

8.3. The Quasi-Newton Update

The matrix H in (4) is a positive-definite quasi-Newton approximation to the Hessian of the Lagrangian function. (For a review of quasi-Newton methods, see Dennis and Schnabel [3].) At the end of each major iteration, a new Hessian approximation \bar{H} is defined as a rank-two modification of H . In E04UCF, the BFGS

quasi-Newton update is used:

$$\bar{H} = H - \frac{1}{s^T H s} H s s^T H + \frac{1}{y^T y} y y^T, \quad (14)$$

where $s = \bar{x} - x$ (the change in x).

In E04UCF, H is required to be positive-definite. If H is

positive-definite, \bar{H} defined by (14) will be positive-definite if

and only if $y^T s$ is positive (see, e.g. Dennis and More [1]).

Ideally, y in (14) would be taken as y_L , the change in gradient

of the Lagrangian function

$$y_L = g - A_N^T(\mu) - g + A_N^T(\mu), \quad (15)$$

where $(\mu)_N$ denotes the QP multipliers associated with the

nonlinear constraints of the original problem. If $y_L^T s$ is not

sufficiently positive, an attempt is made to perform the update with a vector y of the form

$$y = y_L + \sum_{i=1}^m (\omega_i) (a_i(\bar{x})c_i(\bar{x}) - a_i(x)c_i(x)),$$

where $(\omega_i) \geq 0$. If no such vector can be found, the update is

performed with a scaled y_L ; in this case, M is printed to indicate

that the update is modified.

Rather than modifying H itself, the Cholesky factor of the transformed Hessian H (6) is updated, where Q is the matrix from

(5) associated with the active set of the QP subproblem. The update (13) is equivalent to the following update to H :

$$H = H - \frac{1}{Q^T Q} H^T s s^T H + \frac{1}{Q^T Q} y y^T, \quad (16)$$

where $y = Q^T y$, and $s = Q^T s$. This update may be expressed as a rank-one update to R (see Dennis and Schnabel [2]).

9. Example

This section describes one version of the so-called 'hexagon' problem (a different formulation is given as Problem 108 in Hock and Schittkowski [11]). The problem is to determine the hexagon of maximum area such that no two of its vertices are more than one unit apart (the solution is not a regular hexagon).

All constraint types are included (bounds, linear, nonlinear), and the Hessian of the Lagrangian function is not positive-definite at the solution. The problem has nine variables, non-infinite bounds on seven of the variables, four general linear constraints, and fourteen nonlinear constraints.

The objective function is

$$F(x) = -x_2 x_6 + x_1 x_7 - x_3 x_5 - x_4 x_8 + x_1 x_9 + x_2 x_3.$$

The bounds on the variables are

$$x_1 \geq 0, \quad -1 \leq x_3 \leq 1, \quad x_5 \geq 0, \quad x_6 \geq 0, \quad x_7 \geq 0, \quad x_8 \leq 0, \quad \text{and} \quad x_9 \leq 0.$$

Thus,

$$l = (0, -\infty, -1, -\infty, 0, 0, 0, -\infty, -\infty)^T$$

B

$$u = (\text{infty}, \text{infty}, 1, \text{infty}, \text{infty}, \text{infty}, \text{infty}, 0, 0)^T$$

B

The general linear constraints are

$$x_2 - x_1 \geq 0, x_3 - x_2 \geq 0, x_3 - x_4 \geq 0, \text{ and } x_4 - x_5 \geq 0.$$

Hence,

$$\begin{aligned} (0) \quad & (-1 \ 1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0) \quad (\text{infty}) \\ (0) \quad & (0 \ -1 \ 1 \ 0 \ 0 \ 0 \ 0 \ 0 \ 0) \quad (\text{infty}) \\ l = (0), \quad A = & \begin{pmatrix} 0 & 0 & 1 & -1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & -1 & 0 & 0 & 0 & 0 \end{pmatrix} \text{ and } u = (\text{infty}). \\ L(0) \quad L = & \begin{pmatrix} 0 & 0 & 0 & 1 & -1 & 0 & 0 & 0 & 0 \end{pmatrix} \quad L(\text{infty}) \end{aligned}$$

The nonlinear constraints are all of the form $c_i(x) \leq 1$, for $i=1, 2, \dots, 14$; hence, all components of l are $-\text{infty}$, and all components of u are 1. The fourteen functions $\{c_i(x)\}$ are

$$c_1(x) = x_1^2 + x_2^2,$$

$$c_2(x) = (x_2 - x_1)^2 + (x_7 - x_6)^2,$$

$$c_3(x) = (x_3 - x_1)^2 + x_6^2,$$

$$c_4(x) = (x_1 - x_4)^2 + (x_6 - x_8)^2,$$

$$c_5(x) = (x_1 - x_5)^2 + (x_6 - x_9)^2,$$

$$c_6(x) = x_6^2 + x_7^2,$$

$$c_7(x) = (x_3 - x_2)^2 + x_7^2,$$

$$c_8(x) = (x_4 - x_2)^2 + (x_8 - x_7)^2,$$

$$c_9(x) = (x_2 - x_5)^2 + (x_7 - x_9)^2,$$

$$c_{10}(x) = (x_4 - x_3)^2 + x_8^2,$$

$$c_{11}(x) = (x_5 - x_3)^2 + x_9^2,$$

$$c_{12}(x) = x_4^2 + x_8^2,$$

$$c_{13}(x) = (x_4 - x_5)^2 + (x_9 - x_8)^2,$$

$$c_{14}(x) = x_5^2 + x_9^2.$$

An optimal solution (to five figures) is

$$x^* = (0.060947, 0.59765, 1.0, 0.59765, 0.060947, 0.34377, 0.5, \\ -0.5, 0.34377)^T,$$

and $F(x^*) = -1.34996$. (The optimal objective function is unique, but is achieved for other values of x .) Five nonlinear

constraints and one simple bound are active at x^* . The sample

solution output is given later in this section, following the sample main program and problem definition.

Two calls are made to E04UCF in order to demonstrate some of its features. For the first call, the starting point is:

```

                                T
x =(0.1,0.125,0.666666,0.142857,0.111111,0.2,0.25,-0.2,-0.25) .
0
```

All objective and constraint derivatives are specified in the user-provided subroutines OBJFN1 and CONFN1, i.e., the default option Derivative Level =3 is used.

On completion of the first call to E04UCF, the optimal variables are perturbed to produce the initial point for a second run in which the problem functions are defined by the subroutines OBJFN2 and CONFN2. To illustrate one of the finite-difference options in E04UCF, these routines are programmed so that the first six components of the objective gradient and the constant elements of the Jacobian matrix are not specified; hence, the option Derivative Level =0 is chosen. During computation of the finite-difference intervals, the constant Jacobian elements are identified and set, and E04UCF automatically increases the derivative level to 2.

The second call to E04UCF illustrates the use of the Warm Start Level option to utilize the final active set, nonlinear multipliers and approximate Hessian from the first run. Note that Hessian = Yes was specified for the first run so that the array R would contain the Cholesky factor of the approximate Hessian of the Lagrangian.

The two calls to E04UCF illustrate the alternative methods of assigning default parameters. (There is no special significance in the order of these assignments; an options file may just as easily be used to modify parameters set by E04UEF.)

The results are typical of those obtained from E04UCF when solving well behaved (non-trivial) nonlinear problems. The approximate Hessian and working set remain relatively well-conditioned. Similarly the penalty parameters remain small and approximately constant. The numerical results illustrate much of the theoretically predicted behaviour of a quasi-Newton SQP method. As x approaches the solution, only one minor iteration is performed per major iteration, and the Norm Gz and Norm C columns

exhibit the fast linear convergence rate mentioned in Sections 5 and 6. Note that the constraint violations converge earlier than the projected gradient. The final values of the project gradient norm and constraint norm reflect the limiting accuracy of the two quantities. It is possible to achieve almost full precision in the constraint norm but only half precision in the projected gradient norm. Note that the final accuracy in the nonlinear constraints is considerably better than the feasibility tolerance, because the constraint violations are being refined during the last few iterations while the algorithm is working to reduce the projected gradient norm. In this problem, the constraint values and Lagrange multipliers at the solution are 'well balanced', i.e., all the multipliers are approximately the same order of magnitude. The behaviour is typical of a well-scaled problem.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

E04 -- Minimizing or Maximizing a Function E04UDF
 E04UDF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

To supply optional parameters to E04UCF from an external file.

2. Specification

```
SUBROUTINE E04UDF (IOPTNS, INFORM)
  INTEGER          IOPTNS, INFORM
```

3. Description

E04UDF may be used to supply values for optional parameters to E04UCF. E04UDF reads an external file and each line of the file defines a single optional parameter. It is only necessary to supply values for those parameters whose values are to be different from their default values.

Each optional parameter is defined by a single character string of up to 72 characters, consisting of one or more items. The items associated with a given option must be separated by spaces, or equal signs (=). Alphabetic characters may be upper or lower case. The string

```
Print level = 1
```

is an example of a string used to set an optional parameter. For each option the string contains one or more of the following items:

- (a) A mandatory keyword.
- (b) A phrase that qualifies the keyword.
- (c) A number that specifies an INTEGER or real value. Such numbers may be up to 16 contiguous characters in Fortran 77's I, F, E or D formats, terminated by a space if this is not the last item on the line.

Blank strings and comments are ignored. A comment begins with an asterisk (*) and all subsequent characters in the string are regarded as part of the comment.

The file containing the options must start with begin and must finish with end. An example of a valid options file is:

```
Begin * Example options file
Print level =10
End
```

Normally each line of the file is printed as it is read, on the current advisory message unit (see X04ABF), but printing may be suppressed using the keyword nolist. To suppress printing of begin, nolist must be the first option supplied as in the file:

```
Begin
Nolist
Print level = 10
End
```

Printing will automatically be turned on again after a call to E04UCF and may be turned on again at any time by the user by using the keyword list.

Optional parameter settings are preserved following a call to E04UCF, and so the keyword defaults is provided to allow the user to reset all the optional parameters to their default values prior to a subsequent call to E04UCF.

A complete list of optional parameters, their abbreviations, synonyms and default values is given in Section 5.1 of the document for E04UCF.

4. References

None.

5. Parameters

- 1: IOPTNS -- INTEGER Input
On entry: IOPTNS must be the unit number of the options file. Constraint: $0 \leq \text{IOPTNS} \leq 99$.
- 2: INFORM -- INTEGER Output
On exit: INFORM will be zero, if an options file with the current structure has been read. Otherwise INFORM will be positive. Positive values of INFORM indicate that an options file may not have been successfully read as follows:
INFORM = 1
IOPTNS is not in the range [0,99].

INFORM = 2
begin was found, but end-of-file was found before end was found.

INFORM = 3
end-of-file was found before begin was found.

6. Error Indicators and Warnings

If a line is not recognised as a valid option, then a warning message is output on the current advisory message unit (X04ABF).

7. Accuracy

Not applicable.

8. Further Comments

E04UEF may also be used to supply optional parameters to E04UCF.

9. Example

See the example for E04UCF.

%%%

E04 -- Minimizing or Maximizing a Function E04UEF
 E04UEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

To supply individual optional parameters to E04UCF.

2. Specification

```
SUBROUTINE E04UEF (STRING)
CHARACTER*(*)    STRING
```

3. Description

E04UEF may be used to supply values for optional parameters to E04UCF. It is only necessary to call E04UEF for those parameters whose values are to be different from their default values. One call to E04UEF sets one parameter value.

Each optional parameter is defined by a single character string of up to 72 characters, consisting of one or more items. The items associated with a given option must be separated by spaces, or equal signs (=). Alphabetic characters may be upper or lower case. The string

```
Print level = 1
```

is an example of a string used to set an optional parameter. For each option the string contains one or more of the following items:

- (a) A mandatory keyword.

- (b) A phrase that qualifies the keyword.
- (c) A number that specifies an INTEGER or real value. Such numbers may be up to 16 contiguous characters in Fortran 77's I, F, E or D formats, terminated by a space if this is not the last item on the line.

Blank strings and comments are ignored. A comment begins with an asterisk (*) and all subsequent characters in the string are regarded as part of the comment.

Normally, each user-specified option is printed as it is defined, on the current advisory message unit (see X04ABF), but this printing may be suppressed using the keyword `nolist`. Thus the statement

```
CALL E04UEF ('Nolist')
```

suppresses printing of this and subsequent options. Printing will automatically be turned on again after a call to `E04UCF`, and may be turned on again at any time by the user, by using the keyword `list`.

Optional parameter settings are preserved following a call to `E04UCF`, and so the keyword `defaults` is provided to allow the user to reset all the optional parameters to their default values by the statement,

```
CALL E04UEF ('Defaults')
```

prior to a subsequent call to `E04UCF`.

A complete list of optional parameters, their abbreviations, synonyms and default values is given in Section 5.1 of the document for `E04UCF`.

4. References

None.

5. Parameters

- 1: `STRING` -- `CHARACTER*(*)` Input
 On entry: `STRING` must be a single valid option string. See Section 3 above and Section 5.1 of the routine document for `E04UCF`. On entry: `STRING` must be a single valid option

string. See Section 3 above and Section 5.1 of the routine document for E04UCF.

6. Error Indicators and Warnings

If the parameter STRING is not recognised as a valid option string, then a warning message is output on the current advisory message unit (X04ABF).

7. Accuracy

Not applicable.

8. Further Comments

E04UDF may also be used to supply optional parameters to E04UCF.

9. Example

See the example for E04UCF.

E04 -- Minimizing or Maximizing a Function E04YCF
 E04YCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

E04YCF returns estimates of elements of the variance-covariance matrix of the estimated regression coefficients for a nonlinear least squares problem. The estimates are derived from the Jacobian of the function $f(x)$ at the solution.

This routine may be used following any one of the nonlinear least-squares routines E04FCF(*), E04FDF, E04GBF(*), E04GCF, E04GDF(*), E04GEF(*), E04HEF(*), E04HFF(*) .

2. Specification

```
SUBROUTINE E04YCF (JOB, M, N, FSUMSQ, S, V, LV, CJ, WORK,
1                IFAIL)
```

INTEGER JOB, M, N, LV, IFAIL
 DOUBLE PRECISION FSUMSQ, S(N), V(LV,N), CJ(N), WORK(N)

3. Description

E04YCF is intended for use when the nonlinear least-squares

$$T$$

 function, $F(x)=f^T(x)f(x)$, represents the goodness of fit of a
 nonlinear model to observed data. The routine assumes that the
 Hessian of $F(x)$, at the solution, can be adequately approximated

$$T$$

 by $2J^T J$, where J is the Jacobian of $f(x)$ at the solution. The
 estimated variance-covariance matrix C is then given by

$$C = (\sigma^2)^{-1} (J^T J)^{-1} \quad J^T J \text{ non-singular,}$$

where σ^2 is the estimated variance of the residual at the
 solution, x , given by

$$(\sigma^2) = \frac{\sum F(x)}{m-n},$$

m being the number of observations and n the number of variables.

The diagonal elements of C are estimates of the variances of the
 estimated regression coefficients. See the Chapter Introduction
 E04 and Bard [1] and Wolberg [2] for further information on the
 use of C .

T
 When $J^T J$ is singular then C is taken to be

$$C = (\sigma^2)^{-1} (J^T J)^+,$$

$T \quad *$
 where $(J^T J)^+$ is the pseudo-inverse of $J^T J$, but in this case the
 parameter IFAIL is returned as non-zero as a warning to the user
 that J has linear dependencies in its columns. The assumed rank

of J can be obtained from IFAIL.

The routine can be used to find either the diagonal elements of C, or the elements of the jth column of C, or the whole of C.

E04YCF must be preceded by one of the nonlinear least-squares routines mentioned in Section 1, and requires the parameters FSUMSQ, S and V to be supplied by those routines. FSUMSQ is the

residual sum of squares $F(x)$, and S and V contain the singular values and right singular vectors respectively in the singular value decomposition of J. S and V are returned directly by the comprehensive routines E04FCF(*), E04GBF(*), E04GDF(*) and E04HEF(*), but are returned as part of the workspace parameter W from the easy-to-use routines E04FDF, E04GCF, E04GEF(*) and E04HFF(*). In the case of E04FDF, S starts at W(NS), where

$$NS = 6*N + 2*M + M*N + 1 + \max(1, N*(N-1)/2)$$

and in the cases of the remaining easy-to-use routines, S starts at W(NS), where

$$NS = 7*N + 2*M + M*N + N*(N+1)/2 + 1 + \max(1, N*(N-1)/2)$$

The parameter V starts immediately following the elements of S, so that V starts at W(NV), where

$$NV = NS + N.$$

For all the easy-to-use routines the parameter LV must be supplied as N. Thus a call to E04YCF following E04FDF can be illustrated as

```
CALL E04FDF (M, N, X, FSUMSQ, IW, LIW, W, LW, IFAIL)
NS = 6*N + 2*M + M*N + 1 + MAX((1, (N*(N-1))/2)
NV = NS + N
CALL E04YCF (JOB, M, N, FSUMSQ, W(NS), W(NV),
*           N, CJ, WORK, IFAIL)
```

2

where the parameters M, N, FSUMSQ and the $(n+n)$ elements W(NS), W(NS+1), ..., W(NV+N*N-1) must not be altered between the calls to E04FDF and E04YCF. The above illustration also holds for a call to E04YCF following a call to one of E04GCF, E04GEF(*),

E04HFF(*) except that NS must be computed as

$$NS = 7*N + 2*M + M*N + (N*(N+1))/2 + 1 + \text{MAX}((1, N*(N-1))/2)$$

5. Parameters

- 1: JOB -- INTEGER Input
 On entry: which elements of C are returned as follows:
 JOB = -1
 The n by n symmetric matrix C is returned.

 JOB = 0
 The diagonal elements of C are returned.

 JOB > 0
 The elements of column JOB of C are returned.
 Constraint: -1 <= JOB <= N.
- 2: M -- INTEGER Input
 On entry: the number m of observations (residuals $f(x)_i$).
 Constraint: M >= N.
- 3: N -- INTEGER Input
 On entry: the number n of variables $(x)_j$. Constraint: 1 <= N <= M.
- 4: FSUMSQ -- DOUBLE PRECISION Input

 On entry: the sum of squares of the residuals, F(x), at the solution x, as returned by the nonlinear least-squares routine. Constraint: FSUMSQ >= 0.0.
- 5: S(N) -- DOUBLE PRECISION array Input
 On entry: the n singular values of the Jacobian as returned

by the nonlinear least-squares routine. See Section 3 for information on supplying S following one of the easy-to-use routines.

- 6: V(LV,N) -- DOUBLE PRECISION array Input/Output
 On entry: the n by n right-hand orthogonal matrix (the right singular vectors) of J as returned by the nonlinear least-squares routine. See Section 3 for information on supplying V following one of the easy-to-use routines. On exit: when JOB \geq 0 then V is unchanged.

When JOB = -1 then the leading n by n part of V is overwritten by the n by n matrix C. When E04YCF is called with JOB = -1 following an easy-to-use routine this means

2

that C is returned, column by column, in the n elements of

2

W given by W(NV),W(NV+1),...,W(NV+N -1). (See Section 3 for the definition of NV).

- 7: LV -- INTEGER Input
 On entry:
 the first dimension of the array V as declared in the (sub)program from which E04YCF is called.
 When V is passed in the workspace parameter W following one of the easy-to-use least-square routines, LV must be the value N.

- 8: CJ(N) -- DOUBLE PRECISION array Output
 On exit: with JOB = 0, CJ returns the n diagonal elements of C.

With JOB = j>0, CJ returns the n elements of the jth column of C.

When JOB = -1, CJ is not referenced.

- 9: WORK(N) -- DOUBLE PRECISION array Workspace
 When JOB = -1 or 0 then WORK is used as internal workspace.

When JOB > 0, WORK is not referenced.

- 10: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL \neq 0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit. To suppress the output of an error message when soft failure occurs, set IFAIL to 1.

6. Error Indicators and Warnings

Errors or warnings specified by the routine:

IFAIL= 1

On entry JOB < -1,

or JOB > N,

or N < 1,

or M < N,

or FSUMSQ < 0.0.

IFAIL= 2

The singular values are all zero, so that at the solution the Jacobian matrix J has rank 0.

IFAIL> 2

At the solution the Jacobian matrix contains linear, or near linear, dependencies amongst its columns. In this case the required elements of C have still been computed based upon J having an assumed rank given by (IFAIL-2). The rank is computed by regarding singular values SV(j) that are not larger than 10*(epsilon)*SV(1) as zero, where (epsilon) is the machine precision (see X02AJF(*)). Users who expect near linear dependencies at the solution and are happy with this tolerance in determining rank should call E04YCF with IFAIL = 1 in order to prevent termination by P01ABF(*). It is then essential to test the value of IFAIL on exit from E04YCF.

IFAILOverflow

If overflow occurs then either an element of C is very large, or the singular values or singular vectors have been

incorrectly supplied.

7. Accuracy

The computed elements of C will be the exact covariances corresponding to a closely neighbouring Jacobian matrix J.

8. Further Comments

When JOB = -1 the time taken by the routine is approximately
 n^3
 proportional to n . When JOB ≥ 0 the time taken by the routine
 n^2
 is approximately proportional to n .

9. Example

To estimate the variance-covariance matrix C for the least-squares estimates of x_1 , x_2 and x_3 in the model

$$y = x_1 + \frac{t}{x_2^2 + x_3^2}$$

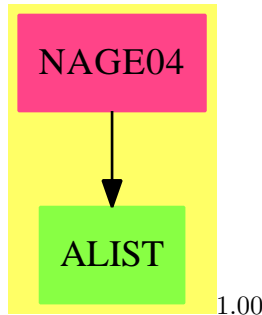

using the 15 sets of data given in the following table:

y	t	t	t
	1	2	3
0.14	1.0	15.0	1.0
0.18	2.0	14.0	2.0
0.22	3.0	13.0	3.0
0.25	4.0	12.0	4.0
0.29	5.0	11.0	5.0
0.32	6.0	10.0	6.0
0.35	7.0	9.0	7.0
0.39	8.0	8.0	8.0
0.37	9.0	7.0	7.0
0.58	10.0	6.0	6.0
0.73	11.0	5.0	5.0
0.96	12.0	4.0	4.0
1.34	13.0	3.0	3.0
2.10	14.0	2.0	2.0
4.39	15.0	1.0	1.0

The program uses (0.5,1.0,1.5) as the initial guess at the position of the minimum and computes the least-squares solution using E04FDF. See the routine document E04FDF for further information.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

)abbrev package NAGE04 NagOptimisationPackage
++ Author: Godfrey Nolan and Mike Dewar
++ Date Created: Jan 1994
++ Date Last Updated: Thu May 12 17:45:09 1994
++ Description:
++ This package uses the NAG Library to perform optimization.
++ An optimization problem involves minimizing a function (called
++ the objective function) of several variables, possibly subject to
++ restrictions on the values of the variables defined by a set of
++ constraint functions. The routines in the NAG Foundation Library
++ are concerned with function minimization only, since the problem
++ of maximizing a given function can be transformed into a
++ minimization problem simply by multiplying the function by -1.
++ See \downlink{Manual Page}{manpageXXe04}.

D02 -- Ordinary Differential Equations

Introduction -- D02

Chapter D02

Ordinary Differential Equations

1. Scope of the Chapter

This chapter is concerned with the numerical solution of ordinary differential equations. There are two main types of problem, those in which all boundary conditions are specified at one point (initial-value problems), and those in which the boundary conditions are distributed between two or more points (boundary-value problems and eigenvalue problems). Routines are available for initial-value problems, two-point boundary-value problems and Sturm-Liouville eigenvalue problems.

2. Background to the Problems

For most of the routines in this chapter a system of ordinary differential equations must be written in the form

$$y'_1 = f_1(x, y_1, y_2, \dots, y_n),$$

$$y'_2 = f_2(x, y_1, y_2, \dots, y_n),$$

.. ..

$$y'_n = f_n(x, y_1, y_2, \dots, y_n),$$

that is the system must be given in first-order form. The n dependent variables (also, the solution) y_1, y_2, \dots, y_n are

functions of the independent variable x , and the differential equations give expressions for the first derivatives $y'_i = dy_i/dx$ in terms of x and y_1, y_2, \dots, y_n . For a system of n first-order

$1 \ 2 \ \dots \ n$
 equations, n associated boundary conditions are usually required to define the solution.

A more general system may contain derivatives of higher order, but such systems can almost always be reduced to the first-order form by introducing new variables. For example, suppose we have the third-order equation

$$z''' + zz'' + k(1-z')^2 = 0.$$

We write $y_1 = z$, $y_2 = z'$, $y_3 = z''$, and the third order equation may then be written as the system of first-order equations

$$\begin{aligned} y_1' &= y_2 \\ y_2' &= y_3 \\ y_3' &= -y_1 y_3 - k(1-y_2)^2. \end{aligned}$$

For this system $n = 3$ and we require 3 boundary conditions in order to define the solution. These conditions must specify values of the dependent variables at certain points. For example, we have an initial-value problem if the conditions are:

$$y_1 = 0 \quad \text{at } x=0$$

$$y_2 = 0 \quad \text{at } x=0$$

$$y_3 = 0.1 \quad \text{at } x=0.$$

These conditions would enable us to integrate the equations numerically from the point $x=0$ to some specified end-point. We have a boundary-value problem if the conditions are:

$$y_1 = 0 \quad \text{at } x=0$$

$$y_2 = 0 \quad \text{at } x=0$$

$$y_2 = 1 \quad \text{at } x=10.$$

These conditions would be sufficient to define a solution in the range $0 \leq x \leq 10$, but the problem could not be solved by direct integration (see Section 2.2). More general boundary conditions are permitted in the boundary-value case.

2.1. Initial-value Problems

To solve first-order systems, initial values of the dependent variables y_i , for $i=1,2,\dots,n$ must be supplied at a given point,

a. Also a point, b , at which the values of the dependent variables are required, must be specified. The numerical solution is then obtained by a step-by-step calculation which approximates values of the variables y_i , for $i=1,2,\dots,n$ at finite intervals

over the required range $[a,b]$. The routines in this chapter adjust the step length automatically to meet specified accuracy tolerances. Although the accuracy tests used are reliable over each step individually, in general an accuracy requirement cannot be guaranteed over a long range. For many problems there may be no serious accumulation of error, but for unstable systems small perturbations of the solution will often lead to rapid divergence of the calculated values from the true values. A simple check for stability is to carry out trial calculations with different tolerances; if the results differ appreciably the system is probably unstable. Over a short range, the difficulty may possibly be overcome by taking sufficiently small tolerances, but over a long range it may be better to try to reformulate the problem.

A special class of initial-value problems are those for which the solutions contain rapidly decaying transient terms. Such problems are called stiff; an alternative way of describing them is to say that certain eigenvalues of the Jacobian matrix $(\text{ddf} / \text{ddy})_{ij}$ have

large negative real parts when compared to others. These problems require special methods for efficient numerical solution; the methods designed for non-stiff problems when applied to stiff problems tend to be very slow, because they need small step

lengths to avoid numerical instability. A full discussion is given in Hall and Watt [6] and a discussion of the methods for stiff problems is given in Berzins, Brankin and Gladwell [1].

2.2. Boundary-value Problems

A full discussion of the design of the methods and codes for boundary-value problems is given in Gladwell [4]. In general, a system of nonlinear differential equations with boundary conditions given at two or more points cannot be guaranteed to have a solution. The solution has to be determined iteratively (if it exists). Finite-difference equations are set up on a mesh of points and estimated values for the solution at the grid points are chosen. Using these estimated values as starting values a Newton iteration is used to solve the finite-difference equations. The accuracy of the solution is then improved by deferred corrections or the addition of points to the mesh or a combination of both. Good initial estimates of the solution may be required in some cases but results may be difficult to compute when the solution varies very rapidly over short ranges. A discussion is given in Chapters 9 and 11 of Gladwell and Sayers [5] and Chapter 4 of Childs et al [2].

2.3. Eigenvalue Problems

Sturm-Liouville problems of the form

$$(p(x)y')' + q(x, \lambda)y = 0$$

with appropriate boundary conditions given at two points, can be solved by a Scaled Pruefer method. In this method the differential equation is transformed to another which can be solved for a specified eigenvalue by a shooting method. A discussion is given in Chapter 11 of Gladwell and Sayers [5] and a complete description is given in Pryce [7].

3. Recommendations on Choice and Use of Routines

There are no routines which deal directly with COMPLEX equations. These may however be transformed to larger systems of real equations of the required form. Split each equation into its real and imaginary parts and solve for the real and imaginary parts of each component of the solution. Whilst this process doubles the size of the system and may not always be appropriate it does make available for use the full range of routines provided presently.

3.1. Initial-value Problems

For simple first-order problems with low accuracy requirements, that is problems on a short range of integration, with derivative functions f_i which are inexpensive to calculate and where only a

few correct figures are required, the best routines to use are likely to be the Runge-Kutta-Merson (RK) routines, D02BBF and D02BHF. For larger problems, over long ranges or with high accuracy requirements the variable-order, variable-step Adams routine D02CJF should usually be preferred. For stiff equations, that is those with rapidly decaying transient solutions, the Backward Differentiation Formula (BDF) variable-order, variable-step routine D02EJF should be used.

There are four routines for initial-value problems, two of which use the Runge-Kutta-Merson method:

D02BBF integrates a system of first order ordinary

differential equations over a range with intermediate output and a choice of error control

D02BHF integrates a system of first order ordinary differential equations with a choice of error control until a position is determined where a function of the solution is zero.

one uses an Adams method:

D02CJF combines the functionality of D02BBF and D02BHF

and one uses a BDF method:

D02EJF combines the functionality of D02BBF and D02BHF.

3.2. Boundary-value Problems

D02GAF may be used for simple boundary-value problems with assigned boundary values. The user may find that convergence is difficult to achieve using D02GAF since only specifying the unknown boundary values and the position of the finite-difference mesh is permitted. In such cases the user may use D02RAF which permits specification of an initial estimate for the solution at all mesh points and allows the calculation to be influenced in other ways too. D02RAF is designed to solve a general nonlinear two-point boundary value problem with nonlinear boundary conditions.

A routine, D02GBF, is also supplied specifically for the general linear two-point boundary-value problem written in a standard

The user is advised to use interpolation routines from the E01 Chapter to obtain solution values at points not on the final mesh.

3.3. Eigenvalue Problems

There is one general purpose routine for eigenvalue problems, D02KEF. It may be used to solve regular or singular second-order Sturm-Liouville problems on a finite or infinite range. Discontinuous coefficient functions can be treated and eigenfunctions can be computed.

Chapter D02

Ordinary Differential Equations

- D02BBF ODEs, IVP, Runge-Kutta-Merson method, over a range, intermediate output
- D02BHF ODEs, IVP, Runge-Kutta-Merson method, until function of solution is zero
- D02CJF ODEs, IVP, Adams method, until function of solution is zero, intermediate output
- D02EJF ODEs, stiff IVP, BDF method, until function of solution is zero, intermediate output
- D02GAF ODEs, boundary value problem, finite difference technique with deferred correction, simple nonlinear problem
- D02GBF ODEs, boundary value problem, finite difference technique with deferred correction, general linear problem
- D02KEF 2nd order Sturm-Liouville problem, regular/singular system, finite/infinite range, eigenvalue and eigenfunction, user-specified break-points
- D02RAF ODEs, general nonlinear boundary value problem, finite difference technique with deferred correction, continuation facility

D02 -- Ordinary Differential Equations

D02BBF

D02BBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

Note for users via the AXIOM system: the interface to this routine has been enhanced for use with AXIOM and is slightly different to that offered in the standard version of the Foundation Library.

1. Purpose

D02BBF integrates a system of first-order ordinary differential equations over an interval with suitable initial conditions, using a Runge-Kutta-Merson method, and returns the solution at points specified by the user.

2. Specification

```

SUBROUTINE D02BBF (X, XEND, M, N, Y, TOL, IRELAB, RESULT,
1                FCN, OUTPUT, W, IFAIL)
  INTEGER          M, N, IRELAB, IFAIL
  DOUBLE PRECISION X, XEND, Y(N), TOL, W(N,7), RESULT(M,N)
  EXTERNAL         FCN, OUTPUT

```

3. Description

The routine integrates a system of ordinary differential equations

$$y'_i = f_i(x, y_1, y_2, \dots, y_n) \quad i=1, 2, \dots, n$$

from $x = X$ to $x = XEND$ using a Merson form of the Runge-Kutta method. The system is defined by a subroutine FCN supplied by the user, which evaluates f_i in terms of x and y_1, y_2, \dots, y_n , and the values of y_1, y_2, \dots, y_n must be given at $x = X$.

The solution is returned via the user-supplied routine OUTPUT at a set of points specified by the user. This solution is obtained by quintic Hermite interpolation on solution values produced by the Runge-Kutta method.

The accuracy of the integration and, indirectly, the interpolation is controlled by the parameters TOL and IRELAB.

For a description of Runge-Kutta methods and their practical implementation see Hall and Watt [1].

4. References

- [1] Hall G and Watt J M (eds) (1976) Modern Numerical Methods for Ordinary Differential Equations. Clarendon Press.

5. Parameters

- 1: X -- DOUBLE PRECISION Input/Output
 On entry: X must be set to the initial value of the independent variable x. On exit: XEND, unless an error has occurred, when it contains the value of x at the error.
- 2: XEND -- DOUBLE PRECISION Input
 On entry: the final value of the independent variable. If XEND < X on entry, integration will proceed in a negative direction.
- 3: M -- INTEGER Input
 On entry: the first dimension of the array RESULT. This will usually be equal to the number of points at which the solution is required.
 Constraint: M > 0.
- 4: N -- INTEGER Input
 On entry: the number of differential equations.
 Constraint: N > 0.
- 5: Y(N) -- DOUBLE PRECISION array Input/Output
 On entry: the initial values of the solution y_1, y_2, \dots, y_n .
 On exit: the computed values of the solution at the final value of X.
- 6: TOL -- DOUBLE PRECISION Input/Output
 On entry: TOL must be set to a positive tolerance for controlling the error in the integration.

D02BBF has been designed so that, for most problems, a reduction in TOL leads to an approximately proportional reduction in the error in the solution at XEND. The relation between changes in TOL and the error at intermediate output points is less clear, but for TOL small enough the error at intermediate output points should also be approximately proportional to TOL. However, the actual relation between TOL and the accuracy achieved cannot be guaranteed. The user is strongly recommended to call D02BBF with more than one value for TOL and to compare the results obtained to estimate their accuracy. In the absence of any prior knowledge, the user might compare the results obtained by calling D02BBF with $TOL=10.0^{-p}$ and $TOL=10.0^{-p-1}$ if p correct

decimal digits in the solution are required. Constraint: $TOL > 0.0$. On exit: normally unchanged. However if the range X to $XEND$ is so short that a small change in TOL is unlikely to make any change in the computed solution then, on return, TOL has its sign changed. This should be treated as a warning that the computed solution is likely to be more accurate than would be produced by using the same value of TOL on a longer range of integration.

7: IRELAB -- INTEGER Input

On entry: IRELAB determines the type of error control. At each step in the numerical solution an estimate of the local error, EST , is made. For the current step to be accepted the following condition must be satisfied:

IRELAB = 0

$$EST = 10.0 \leq TOL * \max\{1.0, |y_1|, |y_2|, \dots, |y_n|\};$$

IRELAB = 1

$EST \leq TOL$;

IRELAB = 2

$$EST \leq TOL * \max\{(\text{epsilon}), |y_1|, |y_2|, \dots, |y_n|\}, \text{ where}$$

(epsilon) is machine precision.

If the appropriate condition is not satisfied, the step size is reduced and the solution is recomputed on the current step.

If the user wishes to measure the error in the computed solution in terms of the number of correct decimal places, then IRELAB should be given the value 1 on entry, whereas if the error requirement is in terms of the number of correct significant digits, then IRELAB should be given the value 2. Where there is no preference in the choice of error test IRELAB = 0 will result in a mixed error test. Constraint: $0 \leq IRELAB \leq 2$.

8: RESULT(M,N) -- DOUBLE PRECISION array Output

On exit: the computed values of the solution at the points given by OUTPUT.

9: FCN -- SUBROUTINE, supplied by the user.

External Procedure

FCN must evaluate the functions f_i (i.e., the derivatives

i

y'_i) for given values of its arguments x, y_1, \dots, y_n .

Its specification is:

```
SUBROUTINE FCN (X, Y, F)
DOUBLE PRECISION X, Y(n), F(n)
```

where n is the actual value of N in the call of D02BBF.

- | | | |
|----|--|--------|
| 1: | X -- DOUBLE PRECISION
On entry: the value of the argument x . | Input |
| 2: | Y(*) -- DOUBLE PRECISION array
On entry: the value of the argument y_i , for
$i=1,2,\dots,n$. | Input |
| 3: | F(*) -- DOUBLE PRECISION array
On exit: the value of f_i , for $i=1,2,\dots,n$. | Output |

FCN must be declared as EXTERNAL in the (sub)program from which D02BBF is called. Parameters denoted as Input must not be changed by this procedure.

- 10: OUTPUT -- SUBROUTINE, supplied by the user.

External Procedure

OUTPUT allows the user to have access to intermediate values of the computed solution at successive points specified by the user. These solution values may be returned to the user via the array RESULT if desired (this is a non-standard feature added for use with the AXIOM system). OUTPUT is initially called by D02BBF with XSOL = X (the initial value of x). The user must reset XSOL to the next point where OUTPUT is to be called, and so on at each call to OUTPUT. If, after a call to OUTPUT, the reset point XSOL is beyond XEND, D02BBF will integrate to XEND with no further calls to OUTPUT; if a call to OUTPUT is required at the point XSOL = XEND, then XSOL must be given precisely the value XEND.

Its specification is:

```
SUBROUTINE OUTPUT(XSOL,Y,COUNT,M,N,RESULT)
DOUBLE PRECISION Y(N),RESULT(M,N),XSOL
INTEGER M,N,COUNT
```

- 1: XSOL -- DOUBLE PRECISION Input/Output
 On entry: the current value of the independent
 variable x. On exit: the next value of x at which
 OUTPUT is to be called.

- 2: Y(N) -- DOUBLE PRECISION array Input
 On entry: the computed solution at the point XSOL.

- 3: COUNT -- INTEGER Input/Output
 On entry: Zero if OUTPUT has not been called before, or
 the previous value of COUNT.
 On exit: A new value of COUNT: this can be used to keep
 track of the number of times OUTPUT has been called.

- 4: M -- INTEGER Input
 On entry: The first dimension of RESULT.

- 5: N -- INTEGER Input
 On entry: The dimension of Y.

- 6: RESULT(M,N) -- DOUBLE PRECISION array Input/Output
 On entry: the previous contents of RESULT.
 On exit: RESULT may be used to return the values of the
 intermediate solutions to the user.

OUTPUT must be declared as EXTERNAL in the (sub)program
 from which D02BBF is called. Parameters denoted as
 Input must not be changed by this procedure.

- 11: W(N,7) -- DOUBLE PRECISION array Workspace

- 12: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not
 familiar with this parameter (described in the Essential
 Introduction) the recommended value is 0.

 On exit: IFAIL = 0 unless the routine detects an error (see
 Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
 On entry TOL <= 0,

or $N \leq 0$,

or $IRELAB \neq 0, 1 \text{ or } 2$.

IFAIL= 2

With the given value of TOL, no further progress can be made across the integration range from the current point $x = X$, or the dependence of the error on TOL would be lost if further progress across the integration range were attempted (see Section 8 for a discussion of this error exit). The components $Y(1), Y(2), \dots, Y(n)$ contain the computed values of the solution at the current point $x = X$.

IFAIL= 3

TOL is too small for the routine to take an initial step (see Section 8). X and $Y(1), Y(2), \dots, Y(n)$ retain their initial values.

IFAIL= 4

$X = XEND$ and $XSOL \neq X$ after the initial call to OUTPUT.

IFAIL= 5

A value of $XSOL$ returned by OUTPUT lies behind the previous value of $XSOL$ in the direction of integration.

IFAIL= 6

A serious error has occurred in an internal call to $D02PAF(*)$. Check all subroutine calls and array dimensions. Seek expert help.

IFAIL= 7

A serious error has occurred in an internal call to $D02XAF(*)$. Check all subroutine calls and array dimensions. Seek expert help.

7. Accuracy

The accuracy depends on TOL, on the mathematical properties of the differential system, on the length of the range of integration and on the method. It can be controlled by varying TOL but the approximate proportionality of the error to TOL holds only for a restricted range of values of TOL. For TOL too large, the underlying theory may break down and the result of varying TOL may be unpredictable. For TOL too small, rounding errors may affect the solution significantly and an error exit with IFAIL = 2 or IFAIL = 3 is possible.

At the intermediate output points the same remarks apply. For large values of TOL it is possible that the errors at some intermediate output points may be much larger than at XEND. In any case, it must not be expected that the error will have the same size at all output points. At any point, it is a combination of the errors arising from the integration of the differential equation and the interpolation. The effect of combining these errors will vary, though in most cases the integration error will dominate.

The user who requires a more reliable estimate of the accuracy achieved than can be obtained by varying TOL, is recommended to call D02BDF(*) where both the solution and a global error estimate are computed.

8. Further Comments

The time taken by the routine depends on the complexity and mathematical properties of the system of differential equations defined by FCN, on the range, the tolerance and the number of calls to OUTPUT. There is also an overhead of the form $a+b*n$ where a and b are machine-dependent computing times.

If the routine fails with IFAIL = 3, then it can be called again with a larger value of TOL (if this has not already been tried). If the accuracy requested is really needed and cannot be obtained with this routine, the system may be very stiff (see below) or so badly scaled that it cannot be solved to the required accuracy.

If the routine fails with IFAIL = 2, it is probable that it has been called with a value of TOL which is so small that the solution cannot be obtained on the range X to XEND. This can happen for well-behaved systems and very small values of TOL. The user should, however, consider whether there is a more fundamental difficulty. For example:

- (a) in the region of a singularity (infinite value) of the solution, the routine will usually stop with IFAIL = 2, unless overflow occurs first. If overflow occurs using D02BBF, D02PAF(*) can be used instead to trap the increasing solution before overflow occurs. In any case, numerical integration cannot be continued through a singularity, and analytic treatment should be considered;
- (b) for 'stiff' equations, where the solution contains rapidly

decaying components, the routine will use very small steps in x (internally to D02BBF) to preserve stability. This will usually exhibit itself by making the computing time excessively long, or occasionally by an exit with IFAIL = 2. Merson's method is not efficient in such cases, and the user should try using D02EBF(*) (Backward Differentiation Formula). To determine whether a problem is stiff, D02BDF(*) may be used.

For well-behaved systems with no difficulties such as stiffness or singularities, the Merson method should work well for low accuracy calculations (three or four figures). For higher accuracy calculations or where FCN is costly to evaluate, Merson's method may not be appropriate and a computationally less expensive method may be D02CBF(*) which uses an Adams method.

Users with problems for which D02BBF is not sufficiently general should consider using D02PAF(*) with D02XAF(*). D02PAF(*) is a more general Merson routine with many facilities including more general error control options and several criteria for interrupting the calculations. D02XAF(*) interpolates on values produced by D02PAF(*).

9. Example

To integrate the following equations (for a projectile)

$$\begin{aligned}
 y' &= \tan(\phi) \\
 v' &= \frac{-0.032 \tan(\phi)}{v} - \frac{0.02v}{\cos(\phi)} \\
 (\phi)' &= \frac{-0.032}{v^2}
 \end{aligned}$$

over an interval $X = 0.0$ to $XEND = 8.0$, starting with values $y=0.0$, $v=0.5$ and $(\phi)=(\pi)/5$ and printing the solution at steps of 1.0. We write $y=Y(1)$, $v=Y(2)$ and $(\phi)=Y(3)$, and we set $TOL=1.0E-4$ and $TOL=1.0E-5$ in turn so that we may compare the solutions. The value of (π) is obtained by using X01AAF(*) .

Note the careful construction of routine OUT to ensure that the

value of XEND is printed.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

D02BHF(3NAG) Foundation Library (12/10/92) D02BHF(3NAG)

D02 -- Ordinary Differential Equations D02BHF
D02BHF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D02BHF integrates a system of first-order ordinary differential equations over an interval with suitable initial conditions, using a Runge-Kutta-Merson method, until a user-specified function of the solution is zero.

2. Specification

```

SUBROUTINE D02BHF (X, XEND, N, Y, TOL, IRELAB, HMAX, FCN,
1                G, W, IFAIL)
  INTEGER          N, IRELAB, IFAIL
  DOUBLE PRECISION X, XEND, Y(N), TOL, HMAX, G, W(N,7)
  EXTERNAL         FCN, G

```

3. Description

The routine advances the solution of a system of ordinary differential equations

$$y'_i = f_i(x, y_1, y_2, \dots, y_n), \quad i=1, 2, \dots, n,$$

from $x = X$ towards $x = XEND$ using a Merson form of the Runge-Kutta method. The system is defined by a subroutine FCN supplied by the user, which evaluates f_i in terms of x and y_1, y_2, \dots, y_n (see Section 5), and the values of y_1, y_2, \dots, y_n must be given at

1 2 n

x = X.

As the integration proceeds, a check is made on the function $g(x,y)$ specified by the user, to determine an interval where it changes sign. The position of this sign change is then determined accurately by interpolating for the solution and its derivative. It is assumed that $g(x,y)$ is a continuous function of the variables, so that a solution of $g(x,y) = 0$ can be determined by searching for a change in sign in $g(x,y)$.

The accuracy of the integration and, indirectly, of the determination of the position where $g(x,y) = 0$, is controlled by the parameter TOL.

For a description of Runge-Kutta methods and their practical implementation see Hall and Watt [1].

4. References

- [1] Hall G and Watt J M (eds) (1976) Modern Numerical Methods for Ordinary Differential Equations. Clarendon Press.

5. Parameters

- 1: X -- DOUBLE PRECISION Input/Output
 On entry: X must be set to the initial value of the independent variable x. On exit: the point where $g(x,y) = 0$. 0 unless an error has occurred, when it contains the value of x at the error. In particular, if $g(x,y) \neq 0.0$ anywhere on the range X to XEND, it will contain XEND on exit.
- 2: XEND -- DOUBLE PRECISION Input
 On entry: the final value of the independent variable x.

 If $XEND < X$ on entry, integration proceeds in a negative direction.
- 3: N -- INTEGER Input
 On entry: the number of differential equations, n.
 Constraint: $N > 0$.
- 4: Y(N) -- DOUBLE PRECISION array Input/Output
 On entry: the initial values of the solution y_1, y_2, \dots, y_n .

1 2 n

 On exit: the computed values of the solution at the final

point $x = X$.

- 5: TOL -- DOUBLE PRECISION Input/Output
 On entry: TOL must be set to a positive tolerance for controlling the error in the integration and in the determination of the position where $g(x,y) = 0.0$.

DO2BHF has been designed so that, for most problems, a reduction in TOL leads to an approximately proportional reduction in the error in the solution obtained in the integration. The relation between changes in TOL and the error in the determination of the position where $g(x,y) = 0.0$ is less clear, but for TOL small enough the error should be approximately proportional to TOL. However, the actual relation between TOL and the accuracy cannot be guaranteed. The user is strongly recommended to call DO2BHF with more than one value for TOL and to compare the results obtained to estimate their accuracy. In the absence of any prior knowledge the user might compare results obtained by calling

-p -p-1

DO2BHF with TOL=10.0 and TOL=10.0 if p correct decimal digits in the solution are required. Constraint: TOL > 0.0.

On exit: normally unchanged. However if the range from $x = X$ to the position where $g(x,y) = 0.0$ (or to the final value of x if an error occurs) is so short that a small change in TOL is unlikely to make any change in the computed solution, then TOL is returned with its sign changed. To check results returned with TOL < 0.0, DO2BHF should be called again with a positive value of TOL whose magnitude is considerably smaller than that of the previous call.

- 6: IRELAB -- INTEGER Input
 On entry: IRELAB determines the type of error control. At each step in the numerical solution an estimate of the local error, EST, is made. For the current step to be accepted the following condition must be satisfied:

IRELAB = 0

$$EST \leq TOL * \max\{1.0, |y_1|, |y_2|, \dots, |y_n|\};$$

IRELAB = 1

$$EST \leq TOL;$$

IRELAB = 2

$$EST \leq TOL * \max\{\epsilon, |y_1|, |y_2|, \dots, |y_n|\},$$

1 2 n

where (epsilon) is machine precision.

If the appropriate condition is not satisfied, the step size is reduced and the solution recomputed on the current step.

If the user wishes to measure the error in the computed solution in terms of the number of correct decimal places, then IRELAB should be given the value 1 on entry, whereas if the error requirement is in terms of the number of correct significant digits, then IRELAB should be given the value 2. Where there is no preference in the choice of error test, IRELAB = 0 will result in a mixed error test. It should be borne in mind that the computed solution will be used in evaluating $g(x,y)$. Constraint: $0 \leq \text{IRELAB} \leq 2$.

7: HMAX -- DOUBLE PRECISION Input
On entry: if HMAX = 0.0, no special action is taken.

If HMAX \neq 0.0, a check is made for a change in sign of $g(x,y)$ at steps not greater than |HMAX|. This facility should be used if there is any chance of 'missing' the change in sign by checking too infrequently. For example, if two changes of sign of $g(x,y)$ are expected within a distance h, say, of each other, then a suitable value for HMAX might be HMAX = h/2. If only one change of sign in $g(x,y)$ is expected on the range X to XEND, then the choice HMAX = 0.0 is most appropriate.

8: FCN -- SUBROUTINE, supplied by the user. External Procedure
FCN must evaluate the functions f_i (i.e., the derivatives y'_i) for given values of its arguments x, y_1, \dots, y_n .

Its specification is:

```
SUBROUTINE FCN (X, Y, F)
DOUBLE PRECISION X, Y(n), F(n)
```

1: X -- DOUBLE PRECISION Input
On entry: the value of the argument x.

2: Y(*) -- DOUBLE PRECISION array Input
On entry: the value of the argument y, for

i

i=1,2,...,n.

3: F(*) -- DOUBLE PRECISION array Output
 On exit: the value of f , for i=1,2,...,n.

i

FCN must be declared as EXTERNAL in the (sub)program from which D02BHF is called. Parameters denoted as Input must not be changed by this procedure.

9: G -- DOUBLE PRECISION FUNCTION, supplied by the user. External Procedure
 G must evaluate the function g(x,y) at a specified point.

Its specification is:

DOUBLE PRECISION FUNCTION G (X, Y)
 DOUBLE PRECISION X, Y(n)
 where n is the actual value of N in the call of D02BHF.

1: X -- DOUBLE PRECISION Input
 On entry: the value of the independent variable x.

2: Y(*) -- DOUBLE PRECISION array Input
 On entry: the value of y , for i=1,2,...,n.

i

G must be declared as EXTERNAL in the (sub)program from which D02BHF is called. Parameters denoted as Input must not be changed by this procedure.

10: W(N,7) -- DOUBLE PRECISION array Workspace

11: IFAIL -- INTEGER Input/Output
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1
 On entry TOL <= 0.0,

or $N \leq 0$,

or $IRELAB \neq 0, 1 \text{ or } 2$.

IFAIL= 2

With the given value of TOL, no further progress can be made across the integration range from the current point $x = X$, or dependence of the error on TOL would be lost if further progress across the integration range were attempted (see Section 8 for a discussion of this error exit). The components $Y(1), Y(2), \dots, Y(n)$ contain the computed values of the solution at the current point $x = X$. No point at which $g(x, y)$ changes sign has been located up to the point $x = X$.

IFAIL= 3

TOL is too small for the routine to take an initial step (see Section 8). X and $Y(1), Y(2), \dots, Y(n)$ retain their initial values.

IFAIL= 4

At no point in the range X to $XEND$ did the function $g(x, y)$ change sign. It is assumed that $g(x, y) = 0.0$ has no solution.

IFAIL= 5

A serious error has occurred in an internal call to C05AZF(*). Check all subroutine calls and array dimensions. Seek expert help.

IFAIL= 6

A serious error has occurred in an internal call to D02PAF(*). Check all subroutine calls and array dimensions. Seek expert help.

IFAIL= 7

A serious error has occurred in an internal call to D02XAF(*). Check all subroutine calls and array dimensions. Seek expert help.

7. Accuracy

The accuracy depends on TOL, on the mathematical properties of the differential system, on the position where $g(x, y) = 0.0$ and on the method. It can be controlled by varying TOL but the approximate proportionality of the error to TOL holds only for a

restricted range of values of TOL. For TOL too large, the underlying theory may break down and the result of varying TOL may be unpredictable. For TOL too small, rounding error may affect the solution significantly and an error exit with IFAIL = 2 or IFAIL = 3 is possible.

The accuracy may also be restricted by the properties of $g(x,y)$. The user should try to code G without introducing any unnecessary cancellation errors.

8. Further Comments

The time taken by the routine depends on the complexity and mathematical properties of the system of differential equations defined by FCN, the complexity of G, on the range, the position of the solution and the tolerance. There is also an overhead of the form $a+b*n$ where a and b are machine-dependent computing times.

For some problems it is possible that D02BHF will return IFAIL = 4 because of inaccuracy of the computed values Y, leading to inaccuracy in the computed values of $g(x,y)$ used in the search for the solution of $g(x,y) = 0.0$. This difficulty can be overcome by reducing TOL sufficiently, and if necessary, by choosing HMAX sufficiently small. If possible, the user should choose XEND well beyond the expected point where $g(x,y) = 0.0$; for example make $|XEND-X|$ about 50 larger than the expected range. As a simple check, if, with XEND fixed, a change in TOL does not lead to a significant change in Y at XEND, then inaccuracy is not a likely source of error.

If the routine fails with IFAIL = 3, then it could be called again with a larger value of TOL if this has not already been tried. If the accuracy requested is really needed and cannot be obtained with this routine, the system may be very stiff (see below) or so badly scaled that it cannot be solved to the required accuracy.

If the routine fails with IFAIL = 2, it is likely that it has been called with a value of TOL which is so small that a solution cannot be obtained on the range X to XEND. This can happen for well-behaved systems and very small values of TOL. The user should, however, consider whether there is a more fundamental difficulty. For example:

- (a) in the region of a singularity (infinite value) of the

solution, the routine will usually stop with IFAIL = 2, unless overflow occurs first. If overflow occurs using D02BHF, D02PAF(*) can be used instead to trap the increasing solution, before overflow occurs. In any case, numerical integration cannot be continued through a singularity, and analytical treatment should be considered;

- (b) for 'stiff' equations, where the solution contains rapidly decaying components, the routine will compute in very small steps in x (internally to D02BHF) to preserve stability. This will usually exhibit itself by making the computing time excessively long, or occasionally by an exit with IFAIL = 2. Merson's method is not efficient in such cases, and the user should try D02EHF(*) which uses a Backward Differentiation Formula method. To determine whether a problem is stiff, D02BDF(*) may be used.

For well-behaved systems with no difficulties such as stiffness or singularities, the Merson method should work well for low accuracy calculations (three or four figures). For high accuracy calculations or where FCN is costly to evaluate, Merson's method may not be appropriate and a computationally less expensive method may be D02CHF(*) which uses an Adams method.

For problems for which D02BHF is not sufficiently general, the user should consider D02PAF(*). D02PAF(*) is a more general Merson routine with many facilities including more general error control options and several criteria for interrupting the calculations. D02PAF(*) can be combined with the rootfinder C05AZF(*) and the interpolation routine D02XAF(*) to solve equations involving y_1, y_2, \dots, y_n and their derivatives.

1 2 n

D02BHF can also be used to solve an equation involving x, y_1, y_2, \dots, y_n and the derivatives of y_1, y_2, \dots, y_n . For example in Section 9, D02BHF is used to find a value of $X > 0.0$ where $Y(1) = 0.0$. It could instead be used to find a turning-point of y_1 by

1

replacing the function $g(x, y)$ in the program by:

```
DOUBLE PRECISION FUNCTION G(X,Y)
DOUBLE PRECISION X,Y(3),F(3)
CALL FCN(X,Y,F)
G = F(1)
RETURN
```

END

This routine is only intended to locate the first zero of $g(x,y)$. If later zeros are required, users are strongly advised to construct their own more general root finding routines as discussed above.

9. Example

To find the value $X > 0.0$ at which $y=0.0$, where y , v , (ϕ) are defined by

$$\begin{aligned} y' &= \tan(\phi) \\ v' &= \frac{-0.032 \tan(\phi)}{v} - \frac{0.02v}{\cos(\phi)} \\ (\phi)' &= -\frac{0.032}{2v} \end{aligned}$$

and where at $X = 0.0$ we are given $y=0.5$, $v=0.5$ and $(\phi)=(\pi)/5$. We write $y=Y(1)$, $v=Y(2)$ and $(\phi)=Y(3)$ and we set $TOL=1.0E-4$ and $TOL=1.0E-5$ in turn so that we can compare the solutions. We expect the solution $X \approx 7.3$ and so we set $XEND = 10.0$ to avoid determining the solution of $y=0.0$ too near the end of the range of integration. The value of (π) is obtained by using $X01AAF(*)$.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

D02CJF(3NAG)

D02CJF

D02CJF(3NAG)

D02 -- Ordinary Differential Equations

D02CJF

D02CJF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

Note for users via the AXIOM system: the interface to this routine has been enhanced for use with AXIOM and is slightly different to that offered in the standard version of the Foundation Library.

1. Purpose

D02CJF integrates a system of first-order ordinary differential equations over a range with suitable initial conditions, using a variable-order, variable-step Adams method until a user-specified function, if supplied, of the solution is zero, and returns the solution at points specified by the user, if desired.

2. Specification

```

SUBROUTINE D02CJF (X, XEND, M, N, Y, FCN, TOL, RELABS,
1                RESULT, OUTPUT, G, W, IFAIL)
  INTEGER          M, N, IFAIL
  DOUBLE PRECISION X, XEND, Y(N), TOL, G, W(28+21*N), RESULT(M,N)
  CHARACTER*1      RELABS
  EXTERNAL         FCN, OUTPUT, G

```

3. Description

The routine advances the solution of a system of ordinary differential equations

$$y'_i = f_i(x, y_1, y_2, \dots, y_n), \quad i=1, 2, \dots, n,$$

from $x = X$ to $x = XEND$ using a variable-order, variable-step Adams method. The system is defined by a subroutine FCN supplied by the user, which evaluates f_i in terms of x and y_1, y_2, \dots, y_n .

The initial values of y_1, y_2, \dots, y_n must be given at $x = X$.

The solution is returned via the user-supplied routine OUTPUT at points specified by the user, if desired: this solution is

obtained by C^1 interpolation on solution values produced by the method. As the integration proceeds a check can be made on the user-specified function $g(x, y)$ to determine an interval where it changes sign. The position of this sign change is then determined

accurately by C^1 interpolation to the solution. It is assumed

that $g(x,y)$ is a continuous function of the variables, so that a solution of $g(x,y)=0.0$ can be determined by searching for a change in sign in $g(x,y)$. The accuracy of the integration, the interpolation and, indirectly, of the determination of the position where $g(x,y)=0.0$, is controlled by the parameters TOL and RELABS.

For a description of Adams methods and their practical implementation see Hall and Watt [1].

4. References

- [1] Hall G and Watt J M (eds) (1976) Modern Numerical Methods for Ordinary Differential Equations. Clarendon Press.

5. Parameters

- 1: X -- DOUBLE PRECISION Input/Output
 On entry: the initial value of the independent variable x .
 Constraint: $X \neq XEND$. On exit: if g is supplied by the user, it contains the point where $g(x,y)=0.0$, unless $g(x,y) \neq 0.0$ anywhere on the range X to $XEND$, in which case, X will contain $XEND$. If g is not supplied by the user it contains $XEND$, unless an error has occurred, when it contains the value of x at the error.
- 2: XEND -- DOUBLE PRECISION Input
 On entry: the final value of the independent variable. If $XEND < X$, integration proceeds in the negative direction.
 Constraint: $XEND \neq X$.
- 3: M -- INTEGER Input
 On entry: the first dimension of the array RESULT. This will usually be equal to the number of points at which the solution is required.
 Constraint: $M > 0$.
- 4: N -- INTEGER Input
 On entry: the number of differential equations.
 Constraint: $N \geq 1$.
- 5: Y(N) -- DOUBLE PRECISION array Input/Output
 On entry: the initial values of the solution y_1, y_2, \dots, y_n
 at $x = X$. On exit: the computed values of the solution at the final point $x = X$.

6: FCN -- SUBROUTINE, supplied by the user.

External Procedure

FCN must evaluate the functions f_i (i.e., the derivatives y'_i) for given values of their arguments x, y_1, y_2, \dots, y_n .

Its specification is:

```
SUBROUTINE FCN (X, Y, F)
```

```
DOUBLE PRECISION X, Y(n), F(n)
```

where n is the actual value of N in the call of D02CJF.

1: X -- DOUBLE PRECISION Input
On entry: the value of the independent variable x.

2: Y(*) -- DOUBLE PRECISION array Input
On entry: the value of the variable y_i , for $i=1,2,\dots,n$.

3: F(*) -- DOUBLE PRECISION array Output
On exit: the value of f_i , for $i=1,2,\dots,n$.

FCN must be declared as EXTERNAL in the (sub)program from which D02CJF is called. Parameters denoted as Input must not be changed by this procedure.

7: TOL -- DOUBLE PRECISION Input
On entry: a positive tolerance for controlling the error in the integration. Hence TOL affects the determination of the position where $g(x,y)=0.0$, if g is supplied.

D02CJF has been designed so that, for most problems, a reduction in TOL leads to an approximately proportional reduction in the error in the solution. However, the actual relation between TOL and the accuracy achieved cannot be guaranteed. The user is strongly recommended to call D02CJF with more than one value for TOL and to compare the results obtained to estimate their accuracy. In the absence of any prior knowledge, the user might compare the results obtained

by calling D02CJF with $TOL=10.0^{-p}$ and $TOL=10.0^{-p-1}$ where p correct decimal digits are required in the solution.

Constraint: $TOL > 0.0$.

8: RELABS -- CHARACTER*1

Input

On entry: the type of error control. At each step in the numerical solution an estimate of the local error, EST, is made. For the current step to be accepted the following condition must be satisfied:

$$EST = \sqrt{\sum_{i=1}^n \left(\frac{e_i}{r_i} \right)^2} \leq 1.0$$

where $(\tau)_r$ and $(\tau)_a$ are defined by

$$RELABS \begin{matrix} r & a \\ (\tau)_r & (\tau)_a \end{matrix}$$

'M' TOL TOL

'A' 0.0 TOL

'R' TOL (epsilon)

'D' TOL TOL

where (epsilon) is a small machine-dependent number and e_i

is an estimate of the local error at y_i , computed

internally. If the appropriate condition is not satisfied, the step size is reduced and the solution is recomputed on the current step. If the user wishes to measure the error in the computed solution in terms of the number of correct decimal places, then RELABS should be set to 'A' on entry, whereas if the error requirement is in terms of the number of correct significant digits, then RELABS should be set to 'R'. If the user prefers a mixed error test, then RELABS should be set to 'M', otherwise if the user has no preference, RELABS should be set to the default 'D'. Note that in this case 'D' is taken to be 'M'. Constraint: RELABS = 'M', 'A', 'R', 'D'.

9: RESULT(M,N) -- DOUBLE PRECISION array

Output

On exit: the computed values of the solution at the points given by OUTPUT.

10: OUTPUT -- SUBROUTINE, supplied by the user.

External Procedure

OUTPUT allows the user to have access to intermediate values of the computed solution at successive points specified by the user. These solution values may be returned to the user via the array RESULT if desired (this is a non-standard feature added for use with the AXIOM system). OUTPUT is initially called by D02CJF with XSOL = X (the initial value of x). The user must reset XSOL to the next point where OUTPUT is to be called, and so on at each call to OUTPUT. If, after a call to OUTPUT, the reset point XSOL is beyond XEND, D02CJF will integrate to XEND with no further calls to OUTPUT; if a call to OUTPUT is required at the point XSOL = XEND, then XSOL must be given precisely the value XEND.

Its specification is:

```
SUBROUTINE OUTPUT(XSOL,Y,COUNT,M,N,RESULT)
DOUBLE PRECISION Y(N),RESULT(M,N),XSOL
INTEGER M,N,COUNT
```

- 1: XSOL -- DOUBLE PRECISION Input/Output
On entry: the current value of the independent variable x. On exit: the next value of x at which OUTPUT is to be called.
- 2: Y(N) -- DOUBLE PRECISION array Input
On entry: the computed solution at the point XSOL.
- 3: COUNT -- INTEGER Input/Output
On entry: Zero if OUTPUT has not been called before, or the previous value of COUNT.
On exit: A new value of COUNT: this can be used to keep track of the number of times OUTPUT has been called.
- 4: M -- INTEGER Input
On entry: The first dimension of RESULT.
- 5: N -- INTEGER Input
On entry: The dimension of Y.
- 6: RESULT(M,N) -- DOUBLE PRECISION array Input/Output
On entry: the previous contents of RESULT.
On exit: RESULT may be used to return the values of the intermediate solutions to the user.

OUTPUT must be declared as EXTERNAL in the (sub)program

from which D02CJF is called. Parameters denoted as Input must not be changed by this procedure.

- 11: G -- DOUBLE PRECISION FUNCTION, supplied by the user.

External Procedure

G must evaluate the function $g(x,y)$ for specified values x,y . It specifies the function g for which the first position x where $g(x,y)=0$ is to be found.

If the user does not require the root finding option, the actual argument G must be the dummy routine D02CJW. (D02CJW is included in the NAG Foundation Library and so need not be supplied by the user).

Its specification is:

DOUBLE PRECISION FUNCTION G (X, Y)

DOUBLE PRECISION X, Y(n)

where n is the actual value of N in the call of D02CJF.

- 1: X -- DOUBLE PRECISION Input

On entry: the value of the independent variable x.

- 2: Y(*) -- DOUBLE PRECISION array Input

On entry: the value of the variable y , for
i

i=1,2,...,n.

G must be declared as EXTERNAL in the (sub)program from which D02CJF is called. Parameters denoted as Input must not be changed by this procedure.

- 12: W(28+21*N) -- DOUBLE PRECISION array Workspace

- 13: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are

output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry TOL \leq 0.0,

or N \leq 0,

or RELABS \neq 'M', 'A', 'R' or 'D'.

or X = XEND.

IFAIL= 2

With the given value of TOL, no further progress can be made across the integration range from the current point $x = X$. (See Section 8 for a discussion of this error exit.) The components $Y(1), Y(2), \dots, Y(N)$ contain the computed values of the solution at the current point $x = X$. If the user has supplied g , then no point at which $g(x,y)$ changes sign has been located up to the point $x = X$.

IFAIL= 3

TOL is too small for D02CJF to take an initial step. X and $Y(1), Y(2), \dots, Y(N)$ retain their initial values.

IFAIL= 4

XSOL has not been reset or XSOL lies behind X in the direction of integration, after the initial call to OUTPUT, if the OUTPUT option was selected.

IFAIL= 5

A value of XSOL returned by OUTPUT has not been reset or lies behind the last value of XSOL in the direction of integration, if the OUTPUT option was selected.

IFAIL= 6

At no point in the range X to $XEND$ did the function $g(x,y)$ change sign, if g was supplied. It is assumed that $g(x,y)=0$ has no solution.

IFAIL= 7

A serious error has occurred in an internal call. Check all subroutine calls and array sizes. Seek expert help.

7. Accuracy

The accuracy of the computation of the solution vector Y may be

controlled by varying the local error tolerance TOL. In general, a decrease in local error tolerance should lead to an increase in accuracy. Users are advised to choose RELABS = 'M' unless they have a good reason for a different choice.

If the problem is a root-finding one, then the accuracy of the root determined will depend on the properties of $g(x,y)$. The user should try to code G without introducing any unnecessary cancellation errors.

8. Further Comments

If more than one root is required then D02QFF(*) should be used.

If the routine fails with IFAIL = 3, then it can be called again with a larger value of TOL if this has not already been tried. If the accuracy requested is really needed and cannot be obtained with this routine, the system may be very stiff (see below) or so badly scaled that it cannot be solved to the required accuracy.

If the routine fails with IFAIL = 2, it is probable that it has been called with a value of TOL which is so small that a solution cannot be obtained on the range X to XEND. This can happen for well-behaved systems and very small values of TOL. The user should, however, consider whether there is a more fundamental difficulty. For example:

- (a) in the region of a singularity (infinite value) of the solution, the routine will usually stop with IFAIL = 2, unless overflow occurs first. Numerical integration cannot be continued through a singularity, and analytic treatment should be considered;
- (b) for 'stiff' equations where the solution contains rapidly decaying components, the routine will use very small steps in x (internally to D02CJF) to preserve stability. This will exhibit itself by making the computing time excessively long, or occasionally by an exit with IFAIL = 2. Adams methods are not efficient in such cases, and the user should try D02EJF.

9. Example

We illustrate the solution of four different problems. In each case the differential system (for a projectile) is

$$y' = \tan(\phi)$$

$$v' = \frac{-0.032 \tan(\phi)}{v} - \frac{0.02v}{\cos(\phi)}$$

$$(\phi)' = \frac{-0.032}{2v}$$

over an interval $X = 0.0$ to $XEND = 10.0$ starting with values $y=0.5$, $v=0.5$ and $(\phi)=(\pi)/5$. We solve each of the following problems with local error tolerances $1.0E-4$ and $1.0E-5$.

- (i) To integrate to $x=10.0$ producing output at intervals of 2.0 until a point is encountered where $y=0.0$.
- (ii) As (i) but with no intermediate output.
- (iii) As (i) but with no termination on a root-finding condition.
- (iv) As (i) but with no intermediate output and no root-finding termination condition.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

D02EJF(3NAG) D02EJF D02EJF(3NAG)

D02 -- Ordinary Differential Equations D02EJF

 D02EJF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

Note for users via the AXIOM system: the interface to this routine has been enhanced for use with AXIOM and is slightly different to that offered in the standard version of the Foundation Library.

1. Purpose

D02EJF integrates a stiff system of first-order ordinary differential equations over an interval with suitable initial conditions, using a variable-order, variable-step method implementing the Backward Differentiation Formulae (BDF), until a user-specified function, if supplied, of the solution is zero, and returns the solution at points specified by the user, if desired.

2. Specification

```

SUBROUTINE D02EJF (X, XEND, M, N, Y, FCN, PEDERV, TOL,
1                RELABS, OUTPUT, G, W, IW, RESULT, IFAIL)
INTEGER          M, N, IW, IFAIL
DOUBLE PRECISION X, XEND, Y(N), TOL, G, W(IW), RESULT(M,N)
CHARACTER*1      RELABS
EXTERNAL         FCN, PEDERV, OUTPUT, G

```

3. Description

The routine advances the solution of a system of ordinary differential equations

$$y'_i = f_i(x, y_1, y_2, \dots, y_n), \quad i=1, 2, \dots, n,$$

from $x = X$ to $x = XEND$ using a variable-order, variable-step method implementing the BDF. The system is defined by a subroutine FCN supplied by the user, which evaluates f_i in terms

of x and y_1, y_2, \dots, y_n (see Section 5). The initial values of y_1, y_2, \dots, y_n must be given at $x = X$.

The solution is returned via the user-supplied routine OUTPUT at points specified by the user, if desired: this solution is

obtained by C^1 interpolation on solution values produced by the method. As the integration proceeds a check can be made on the user-specified function $g(x, y)$ to determine an interval where it changes sign. The position of this sign change is then determined

accurately by C^1 interpolation to the solution. It is assumed that $g(x, y)$ is a continuous function of the variables, so that a solution of $g(x, y) = 0.0$ can be determined by searching for a

change in sign in $g(x,y)$. The accuracy of the integration, the interpolation and, indirectly, of the determination of the position where $g(x,y) = 0.0$, is controlled by the parameters TOL and RELABS. The Jacobian of the system $y'=f(x,y)$ may be supplied in routine PEDERV, if it is available.

For a description of BDF and their practical implementation see Hall and Watt [1].

4. References

- [1] Hall G and Watt J M (eds) (1976) Modern Numerical Methods for Ordinary Differential Equations. Clarendon Press.

5. Parameters

- 1: X -- DOUBLE PRECISION Input/Output
 On entry: the initial value of the independent variable x.
 Constraint: $X \neq XEND$ On exit: if G is supplied by the user, X contains the point where $g(x,y) = 0.0$, unless $g(x,y) \neq 0.0$ anywhere on the range X to XEND, in which case, X will contain XEND. If G is not supplied X contains XEND, unless an error has occurred, when it contains the value of x at the error.
- 2: XEND -- DOUBLE PRECISION Input
 On entry: the final value of the independent variable. If $XEND < X$, integration proceeds in the negative direction.
 Constraint: $XEND \neq X$.
- 3: M -- INTEGER Input
 On entry: the first dimension of the array RESULT. This will usually be equal to the number of points at which the solution is required.
 Constraint: $M > 0$.
- 4: N -- INTEGER Input
 On entry: the number of differential equations, n.
 Constraint: $N \geq 1$.
- 5: Y(N) -- DOUBLE PRECISION array Input/Output
 On entry: the initial values of the solution y_1, y_2, \dots, y_n
 at $x = X$. On exit: the computed values of the solution at the final point $x = X$.

- 6: FCN -- SUBROUTINE, supplied by the user.

External Procedure

FCN must evaluate the functions f_i (i.e., the derivatives y'_i) for given values of their arguments x, y_1, y_2, \dots, y_n .

Its specification is:

```
SUBROUTINE FCN (X, Y, F)
```

```
DOUBLE PRECISION X, Y(n), F(n)
```

where n is the actual value of N in the call of D02EJF.

1: X -- DOUBLE PRECISION Input
On entry: the value of the independent variable x.

2: Y(*) -- DOUBLE PRECISION array Input
On entry: the value of the variable y_i , for $i=1,2,\dots,n$.

3: F(*) -- DOUBLE PRECISION array Output
On exit: the value of f_i , for $i=1,2,\dots,n$.

FCN must be declared as EXTERNAL in the (sub)program from which D02EJF is called. Parameters denoted as Input must not be changed by this procedure.

- 7: PEDERV -- SUBROUTINE, supplied by the user.

External Procedure

PEDERV must evaluate the Jacobian of the system (that is, the partial derivatives $\frac{ddf_i}{ddy_j}$) for given values of the variables x, y_1, y_2, \dots, y_n .

Its specification is:

```
SUBROUTINE PEDERV (X, Y, PW)
```

```
DOUBLE PRECISION X, Y(n), PW(n,n)
```

where n is the actual value of N in the call of D02EJF.

1: X -- DOUBLE PRECISION Input

On entry: the value of the independent variable x .

2: $Y(*)$ -- DOUBLE PRECISION array Input

On entry: the value of the variable y , for
 i
 $i=1,2,\dots,n$.

3: $PW(n,*)$ -- DOUBLE PRECISION array Output
 ddf

i
 On exit: the value of $----$, for $i,j=1,2,\dots,n$.
 ddy
 j

If the user does not wish to supply the Jacobian, the actual argument PEDERV must be the dummy routine D02EJY. (D02EJY is included in the NAG Foundation Library and so need not be supplied by the user. The name may be implementation dependent: see the User's Note for your implementation for details).

PEDERV must be declared as EXTERNAL in the (sub)program from which D02EJF is called. Parameters denoted as Input must not be changed by this procedure.

8: TOL -- DOUBLE PRECISION Input/Output

On entry: TOL must be set to a positive tolerance for controlling the error in the integration. Hence TOL affects the determination of the position where $g(x,y) = 0.0$, if G is supplied.

D02EJF has been designed so that, for most problems, a reduction in TOL leads to an approximately proportional reduction in the error in the solution. However, the actual relation between TOL and the accuracy achieved cannot be guaranteed. The user is strongly recommended to call D02EJF with more than one value for TOL and to compare the results obtained to estimate their accuracy. In the absence of any prior knowledge, the user might compare the results obtained

by calling D02EJF with $TOL=10^{-p}$ and $TOL=10^{-p-1}$ if p correct decimal digits are required in the solution. Constraint: $TOL > 0.0$. On exit: normally unchanged. However if the range X to $XEND$ is so short that a small change in TOL is unlikely to make any change in the computed solution, then, on return, TOL has its sign changed.

9: RELABS -- CHARACTER*1 Input

On entry: the type of error control. At each step in the numerical solution an estimate of the local error, EST, is made. For the current step to be accepted the following condition must be satisfied:

$$EST = \sqrt{\sum_{i=1}^n \frac{1}{n} \left(e_i / ((\tau_r) * |y_i| + (\tau_a)) \right)^2} \leq 1.0$$

where (τ_r) and (τ_a) are defined by

RELABS	(τ_r)	(τ_a)
	r	a
'M'	TOL	TOL
'A'	0.0	TOL
'R'	TOL	(epsilon)
'D'	TOL	(epsilon)

where (epsilon) is a small machine-dependent number and e_i

is an estimate of the local error at y_i , computed

internally. If the appropriate condition is not satisfied, the step size is reduced and the solution is recomputed on the current step. If the user wishes to measure the error in the computed solution in terms of the number of correct decimal places, then RELABS should be set to 'A' on entry, whereas if the error requirement is in terms of the number of correct significant digits, then RELABS should be set to 'R'. If the user prefers a mixed error test, then RELABS should be set to 'M', otherwise if the user has no preference, RELABS should be set to the default 'D'. Note that in this case 'D' is taken to be 'R'. Constraint: RELABS = 'A', 'M', 'R' or 'D'.

10: OUTPUT -- SUBROUTINE, supplied by the user.

External Procedure

OUTPUT allows the user to have access to intermediate values of the computed solution at successive points specified by the user. These solution values may be returned to the user via the array RESULT if desired (this is a non-standard feature added for use with the AXIOM system). OUTPUT is initially

15.19. PACKAGE NAGD02 NAGORDINARYDIFFERENTIALEQUATIONSPACKAGE2313

called by D02EJF with XSOL = X (the initial value of x). The user must reset XSOL to the next point where OUTPUT is to be called, and so on at each call to OUTPUT. If, after a call to OUTPUT, the reset point XSOL is beyond XEND, D02EJF will integrate to XEND with no further calls to OUTPUT; if a call to OUTPUT is required at the point XSOL = XEND, then XSOL must be given precisely the value XEND.

Its specification is:

```
SUBROUTINE OUTPUT(XSOL,Y,COUNT,M,N,RESULT)
DOUBLE PRECISION Y(N),RESULT(M,N),XSOL
INTEGER M,N,COUNT
```

- 1: XSOL -- DOUBLE PRECISION Input/Output
On entry: the current value of the independent variable x. On exit: the next value of x at which OUTPUT is to be called.
- 2: Y(N) -- DOUBLE PRECISION array Input
On entry: the computed solution at the point XSOL.
- 3: COUNT -- INTEGER Input/Output
On entry: Zero if OUTPUT has not been called before, or the previous value of COUNT.
On exit: A new value of COUNT: this can be used to keep track of the number of times OUTPUT has been called.
- 4: M -- INTEGER Input
On entry: The first dimension of RESULT.
- 5: N -- INTEGER Input
On entry: The dimension of Y.
- 6: RESULT(M,N) -- DOUBLE PRECISION array Input/Output
On entry: the previous contents of RESULT.
On exit: RESULT may be used to return the values of the intermediate solutions to the user.

OUTPUT must be declared as EXTERNAL in the (sub)program from which D02EJF is called. Parameters denoted as Input must not be changed by this procedure.

- 11: G -- DOUBLE PRECISION FUNCTION, supplied by the user. External Procedure
G must evaluate the function $g(x,y)$ for specified values x,y

Its specification is:

where n is the actual value of N in the call of D02EJF.

- If the user does not require the root finding option, the actual argument G must be the dummy routine D02EJW. (D02EJW is included in the NAG Foundation Library and so need not be supplied by the user). G must be declared as EXTERNAL in the (sub)program from which D02EJF is called. Parameters denoted as Input must not be changed by this procedure.

- ## 6. Error Indicators and Warnings

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry TOL <= 0.0,

or X = XEND,

or N <= 0,

or RELABS /= 'M', 'A', 'R', 'D'.

or IW<(12+N)*N+50.

IFAIL= 2

With the given value of TOL, no further progress can be made across the integration range from the current point $x = X$. (See Section 5 for a discussion of this error test.) The components $Y(1), Y(2), \dots, Y(n)$ contain the computed values of the solution at the current point $x = X$. If the user has supplied G, then no point at which $g(x,y)$ changes sign has been located up to the point $x = X$.

IFAIL= 3

TOL is too small for D02EJF to take an initial step. X and $Y(1), Y(2), \dots, Y(n)$ retain their initial values.

IFAIL= 4

XSOL lies behind X in the direction of integration, after the initial call to OUTPUT, if the OUTPUT option was selected.

IFAIL= 5

A value of XSOL returned by OUTPUT lies behind the last value of XSOL in the direction of integration, if the OUTPUT option was selected.

IFAIL= 6

At no point in the range X to XEND did the function $g(x,y)$ change sign, if G was supplied. It is assumed that $g(x,y) = 0$ has no solution.

IFAIL= 7

A serious error has occurred in an internal call to

C05AZF(*). Check all subroutine calls and array dimensions.
Seek expert help.

IFAIL= 8

A serious error has occurred in an internal call to
D02XKF(*). Check all subroutine calls and array dimensions.
Seek expert help.

IFAIL= 9

A serious error has occurred in an internal call to
D02NMF(*). Check all subroutine calls and array dimensions.
Seek expert help.

7. Accuracy

The accuracy of the computation of the solution vector Y may be controlled by varying the local error tolerance TOL . In general, a decrease in local error tolerance should lead to an increase in accuracy. Users are advised to choose $RELABS = 'R'$ unless they have a good reason for a different choice. It is particularly appropriate if the solution decays.

If the problem is a root-finding one, then the accuracy of the root determined will depend strongly on $\frac{ddg}{ddx}$ and $\frac{ddg}{ddy}$, for $i=1,2,\dots,n$. Large values for these quantities may imply large errors in the root.

8. Further Comments

If more than one root is required, then to determine the second and later roots D02EJF may be called again starting a short distance past the previously determined roots. Alternatively the user may construct his own root finding code using D02QDF(*) (or the routines of the subchapter D02M-D02N), D02XKF(*) and C05AZF(*) .

If it is easy to code, the user should supply the routine PEDERV. However, it is important to be aware that if PEDERV is coded incorrectly, a very inefficient integration may result and possibly even a failure to complete the integration (IFAIL = 2).

9. Example

We illustrate the solution of five different problems. In each case the differential system is the well-known stiff Robertson problem.

$$\begin{aligned} a' &= -0.04a - 10^4 bc \\ b' &= 0.04a - 10^4 bc - 3 \times 10^7 b^2 \\ c' &= 3 \times 10^7 b^2 \end{aligned}$$

with initial conditions $a=1.0$, $b=c=0.0$ at $x=0.0$. We solve each of the following problems with local error tolerances $1.0E-3$ and $1.0E-4$.

- (i) To integrate to $x=10.0$ producing output at intervals of 2.0 until a point is encountered where $a=0.9$. The Jacobian is calculated numerically.
- (ii) As (i) but with the Jacobian calculated analytically.
- (iii) As (i) but with no intermediate output.
- (iv) As (i) but with no termination on a root-finding condition.
- (v) Integrating the equations as in (i) but with no intermediate output and no root-finding termination condition.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%

D02GAF(3NAG) Foundation Library (12/10/92) D02GAF(3NAG)

D02 -- Ordinary Differential Equations D02GAF
D02GAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D02GAF solves the two-point boundary-value problem with assigned boundary values for a system of ordinary differential equations, using a deferred correction technique and a Newton iteration.

2. Specification

```

SUBROUTINE D02GAF (U, V, N, A, B, TOL, FCN, MNP, X, Y, NP,
1                W, LW, IW, LIW, IFAIL)
  INTEGER          N, MNP, NP, LW, IW(LIW), LIW, IFAIL
  DOUBLE PRECISION U(N,2), V(N,2), A, B, TOL, X(MNP), Y
1                (N,MNP), W(LW)
  EXTERNAL         FCN

```

3. Description

D02GAF solves a two-point boundary-value problem for a system of n differential equations in the interval $[a,b]$. The system is written in the form

$$y'_i = f(x, y_1, y_2, \dots, y_n), \quad i=1,2,\dots,n \quad (1)$$

and the derivatives are evaluated by a subroutine FCN supplied by the user. Initially, n boundary values of the variables y_i must

be specified (assigned), some at a and some at b . The user also supplies estimates of the remaining n boundary values and all the boundary values are used in constructing an initial approximation to the solution. This approximate solution is corrected by a finite-difference technique with deferred correction allied with a Newton iteration to solve the finite-difference equations. The technique used is described fully in Pereyra [1]. The Newton

iteration requires a Jacobian matrix $\frac{dy_i}{dy_j}$ and this is calculated by numerical differentiation using an algorithm described in Curtis et al [2].

The user supplies an absolute error tolerance and may also supply an initial mesh for the construction of the finite-difference equations (alternatively a default mesh is used). The algorithm constructs a solution on a mesh defined by adding points to the initial mesh. This solution is chosen so that the error is

everywhere less than the user's tolerance and so that the error is approximately equidistributed on the final mesh. The solution is returned on this final mesh.

If the solution is required at a few specific points then these should be included in the initial mesh. If on the other hand the solution is required at several specific points then the user should use the interpolation routines provided in Chapter E01 if these points do not themselves form a convenient mesh.

4. References

- [1] Pereyra V (1979) PASVA3: An Adaptive Finite-Difference Fortran Program for First Order Nonlinear, Ordinary Boundary Problems. Codes for Boundary Value Problems in Ordinary Differential Equations. Lecture Notes in Computer Science. (ed B Childs, M Scott, J W Daniel, E Denman and P Nelson) 76 Springer-Verlag.
- [2] Curtis A R, Powell M J D and Reid J K (1974) On the Estimation of Sparse Jacobian Matrices. J. Inst. Maths Applics. 13 117--119.

5. Parameters

- 1: U(N,2) -- DOUBLE PRECISION array Input
 On entry: U(i,1) must be set to the known (assigned) or estimated values of y at a and U(i,2) must be set to the known or estimated values of y at b, for $i=1,2,\dots,n$.
- 2: V(N,2) -- DOUBLE PRECISION array Input
 On entry: V(i,j) must be set to 0.0 if U(i,j) is a known (assigned) value and to 1.0 if U(i,j) is an estimated value, $i=1,2,\dots,n$; $j=1,2$. Constraint: precisely N of the V(i,j) must be set to 0.0, i.e., precisely N of the U(i,j) must be known values, and these must not be all at a or all at b.
- 3: N -- INTEGER Input
 On entry: the number of equations. Constraint: $N \geq 2$.
- 4: A -- DOUBLE PRECISION Input
 On entry: the left-hand boundary point, a.
- 5: B -- DOUBLE PRECISION Input

On entry: the right-hand boundary point, b . Constraint: $B > A$.

- 6: TOL -- DOUBLE PRECISION Input
 On entry: a positive absolute error tolerance. If

$$a = x_1 < x_2 < \dots < x_{NP} = b$$

 is the final mesh, $z_j(x_i)$ is the j th component of the
 approximate solution at x_i , and $y_j(x_i)$ is the j th component
 of the true solution of equation (1) (see Section 3) and the
 boundary conditions, then, except in extreme cases, it is
 expected that

$$|z_j(x_i) - y_j(x_i)| \leq \text{TOL}, \quad i=1,2,\dots,NP; j=1,2,\dots,n \quad (2)$$

 Constraint: $\text{TOL} > 0.0$.

- 7: FCN -- SUBROUTINE, supplied by the user. External Procedure
 FCN must evaluate the functions f_i (i.e., the derivatives
 y'_i) at the general point x .

Its specification is:

```
SUBROUTINE FCN (X, Y, F)
  DOUBLE PRECISION X, Y(n), F(n)
where n is the actual value of N in the call of D02GAF.
```

- 1: X -- DOUBLE PRECISION Input
 On entry: the value of the argument x .
- 2: Y(*) -- DOUBLE PRECISION array Input
 On entry: the value of the argument y_i , for
 $i=1,2,\dots,n$.
- 3: F(*) -- DOUBLE PRECISION array Output
 On exit: the values of f_i , for $i=1,2,\dots,n$.

FCN must be declared as EXTERNAL in the (sub)program
 from which D02GAF is called. Parameters denoted as
 Input must not be changed by this procedure.

- 8: MNP -- INTEGER Input
 On entry: the maximum permitted number of mesh points.
 Constraint: MNP \geq 32.
- 9: X(MNP) -- DOUBLE PRECISION array Input/Output
 On entry: if NP \geq 4 (see NP below), the first NP elements must define an initial mesh. Otherwise the elements of X need not be set. Constraint:

$$A = X(1) < X(2) < \dots < X(NP) = B \text{ for } NP \geq 4 \quad (3)$$
 On exit: X(1), X(2), ..., X(NP) define the final mesh (with the returned value of NP) satisfying the relation (3).
- 10: Y(N,MNP) -- DOUBLE PRECISION array Output
 On exit: the approximate solution $z(x)$ satisfying (2), on the final mesh, that is

$$Y(j,i) = z(x_j), \quad i=1,2,\dots,NP; j=1,2,\dots,n,$$
 where NP is the number of points in the final mesh.
 The remaining columns of Y are not used.
- 11: NP -- INTEGER Input/Output
 On entry: determines whether a default or user-supplied mesh is used. If NP = 0, a default value of 4 for NP and a corresponding equispaced mesh X(1), X(2), ..., X(NP) are used. If NP \geq 4, then the user must define an initial mesh using the array X as described. Constraint: NP = 0 or $4 \leq NP \leq$ MNP. On exit: the number of points in the final (returned) mesh.
- 12: W(LW) -- DOUBLE PRECISION array Workspace
- 13: LW -- INTEGER Input
 On entry: the length of the array W as declared in the calling (sub)program. Constraint: LW \geq MNP*(3N² + 6N + 2) + 4N + 4N²
- 14: IW(LIW) -- INTEGER array Workspace
- 15: LIW -- INTEGER Input
 On entry: the length of the array IW as declared in the calling (sub)program. Constraint: LIW \geq MNP*(2N + 1) + N + 4N + 2.
- 16: IFAIL -- INTEGER Input/Output

For this routine, the normal use of IFAIL is extended to control the printing of error and warning messages as well as specifying hard or soft failure (see the Essential Introduction).

Before entry, IFAIL must be set to a value with the decimal expansion cba , where each of the decimal digits c , b and a must have a value of 0 or 1.

$a=0$ specifies hard failure, otherwise soft failure;

$b=0$ suppresses error messages, otherwise error messages will be printed (see Section 6);

$c=0$ suppresses warning messages, otherwise warning messages will be printed (see Section 6).

The recommended value for inexperienced users is 110 (i.e., hard failure with all messages printed).

Unless the routine detects an error (see Section 6), IFAIL contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

If on entry $IFAIL = 0$ or -1 , explanatory error messages are output on the current error message unit (as defined by X04AAF).

$IFAIL= 1$

One or more of the parameters N , TOL , NP , MNP , LW or LIW has been incorrectly set, or $B \leq A$, or the condition (3) on X is not satisfied, or the number of known boundary values (specified by V) is not N .

$IFAIL= 2$

The Newton iteration has failed to converge. This could be due to there being too few points in the initial mesh or to the initial approximate solution being too inaccurate. If this latter reason is suspected the user should use subroutine D02RAF instead. If the warning 'Jacobian matrix is singular' is printed this could be due to specifying zero estimated boundary values and these should be varied. This warning could also be printed in the unlikely event of the Jacobian matrix being calculated inaccurately. If the user cannot make changes to prevent the warning then subroutine D02RAF should be used.

IFAIL= 3

The Newton iteration has reached round-off level. It could be, however, that the answer returned is satisfactory. This error might occur if too much accuracy is requested.

IFAIL= 4

A finer mesh is required for the accuracy requested; that is MNP is not large enough.

IFAIL= 5

A serious error has occurred in a call to D02GAF. Check all array subscripts and subroutine parameter lists in calls to D02GAF. Seek expert help.

7. Accuracy

The solution returned by the routine will be accurate to the user's tolerance as defined by the relation (2) except in extreme circumstances. If too many points are specified in the initial mesh, the solution may be more accurate than requested and the error may not be approximately equidistributed.

8. Further Comments

The time taken by the routine depends on the difficulty of the problem, the number of mesh points used (and the number of different meshes used), the number of Newton iterations and the number of deferred corrections.

The user is strongly recommended to set IFAIL to obtain self-explanatory error messages, and also monitoring information about the course of the computation. The user may select the channel numbers on which this output is to appear by calls of X04AAF (for error messages) or X04ABF (for monitoring information) - see Section 9 for an example. Otherwise the default channel numbers will be used, as specified in the implementation document.

A common cause of convergence problems in the Newton iteration is the user specifying too few points in the initial mesh. Although the routine adds points to the mesh to improve accuracy it is unable to do so until the solution on the initial mesh has been calculated in the Newton iteration.

If the user specifies zero known and estimated boundary values, the routine constructs a zero initial approximation and in many

cases the Jacobian is singular when evaluated for this approximation, leading to the breakdown of the Newton iteration.

The user may be unable to provide a sufficiently good choice of initial mesh and estimated boundary values, and hence the Newton iteration may never converge. In this case the continuation facility provided in D02RAF is recommended.

In the case where the user wishes to solve a sequence of similar problems, the final mesh from solving one case is strongly recommended as the initial mesh for the next.

9. Example

We solve the differential equation

$$y'' = -y^2 - (\text{beta})(1 - y')$$

with boundary conditions

$$y(0) = y'(0) = 0,$$

$$y'(10) = 1$$

for $(\text{beta})=0.0$ and $(\text{beta})=0.2$ to an accuracy specified by $\text{TOL}=1.0 \text{ E}-3$. We solve first the simpler problem with $(\text{beta})=0.0$ using an equispaced mesh of 26 points and then we solve the problem with $(\text{beta})=0.2$ using the final mesh from the first problem.

Note the call to X04ABF prior to the call to D02GAF.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

D02GBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is

not included in the Foundation Library.

1. Purpose

D02GBF solves a general linear two-point boundary value problem for a system of ordinary differential equations using a deferred correction technique.

2. Specification

```

      SUBROUTINE D02GBF (A, B, N, TOL, FCNF, FCNG, C, D, GAM,
1      MNP, X, Y, NP, W, LW, IW, LIW, IFAIL)
      INTEGER          N, MNP, NP, LW, IW(LIW), LIW, IFAIL
      DOUBLE PRECISION A, B, TOL, C(N,N), D(N,N), GAM(N), X(MNP),
1      Y(N,MNP), W(LW)
      EXTERNAL          FCNF, FCNG

```

3. Description

D02GBF solves the linear two-point boundary value problem for a system of n ordinary differential equations in the interval

$[a,b]$. The system is written in the form

$$y' = F(x)y + g(x) \quad (1)$$

and the boundary conditions are written in the form

$$Cy(a) + Dy(b) = (\text{gamma}) \quad (2)$$

Here $F(x)$, C and D are n by n matrices, and $g(x)$ and (gamma) are n -component vectors. The approximate solution to (1) and (2) is found using a finite-difference method with deferred correction. The algorithm is a specialisation of that used in subroutine D02RAF which solves a nonlinear version of (1) and (2). The nonlinear version of the algorithm is described fully in Pereyra [1].

The user supplies an absolute error tolerance and may also supply an initial mesh for the construction of the finite-difference equations (alternatively a default mesh is used). The algorithm constructs a solution on a mesh defined by adding points to the initial mesh. This solution is chosen so that the error is everywhere less than the user's tolerance and so that the error is approximately equidistributed on the final mesh. The solution is returned on this final mesh.

If the solution is required at a few specific points then these should be included in the initial mesh. If, on the other hand, the solution is required at several specific points, then the user should use the interpolation routines provided in Chapter E01 if these points do not themselves form a convenient mesh.

- [1] Pereyra V (1979) PASVA3: An Adaptive Finite-Difference Fortran Program for First Order Nonlinear, Ordinary Boundary Problems. Codes for Boundary Value Problems in Ordinary Differential Equations. Lecture Notes in Computer Science. (ed B Childs, M Scott, J W Daniel, E Denman and P Nelson) 76 Springer-Verlag.

5. Parameters

1: A -- DOUBLE PRECISION Input
On entry: the left-hand boundary point, a.

2: B -- DOUBLE PRECISION Input
On entry: the right-hand boundary point, b. Constraint: B > A.

3: N -- INTEGER Input
On entry: the number of equations; that is n is the order of system (1). Constraint: N >= 2.

4: TOL -- DOUBLE PRECISION Input
On entry: a positive absolute error tolerance. If

$$a = x_1 < x_2 < \dots < x_{NP} = b$$
is the final mesh, $z(x)$ is the approximate solution from D02GBF and $y(x)$ is the true solution of equations (1) and (2) then, except in extreme cases, it is expected that

$$\|z - y\| \leq \text{TOL} \quad (3)$$

where

$$\|u\| = \max_{1 \leq i \leq N} \max_{1 \leq j \leq NP} |u(x_j)|.$$

Constraint: TOL > 0.0.

5: FCNF -- SUBROUTINE, supplied by the user. External Procedure
FCNF must evaluate the matrix $F(x)$ in (1) at a general point x .

Its specification is:

```
SUBROUTINE FCN (X, F)
  DOUBLE PRECISION X, F(n,n)
```

where n is the actual value of N in the call of D02GBF.

- 1: X -- DOUBLE PRECISION Input
On entry: the value of the independent variable x.
- 2: F(n,n) -- DOUBLE PRECISION array Output
On exit: the (i,j)th element of the matrix F(x), for
i,j=1,2,...,n. (See Section 9 for an example.)
FCN must be declared as EXTERNAL in the (sub)program
from which D02GBF is called. Parameters denoted as
Input must not be changed by this procedure.
- 6: FCNG -- SUBROUTINE, supplied by the user. External Procedure
FCNG must evaluate the vector g(x) in (1) at a general point
x.

Its specification is:

```
SUBROUTINE FCNG (X, G)
  DOUBLE PRECISION X, G(n)
```

where n is the actual value of N in the call of D02GBF.

- 1: X -- DOUBLE PRECISION Input
On entry: the value of the independent variable x.
- 2: G(*) -- DOUBLE PRECISION array Output
On exit: the ith element of the vector g(x), for
i=1,2,...,n. (See Section 9 for an example.)
FCNG must be declared as EXTERNAL in the (sub)program
from which D02GBF is called. Parameters denoted as
Input must not be changed by this procedure.
- 7: C(N,N) -- DOUBLE PRECISION array Input/Output
- 8: D(N,N) -- DOUBLE PRECISION array Input/Output
- 9: GAM(N) -- DOUBLE PRECISION array Input/Output
On entry: the arrays C and D must be set to the matrices C
and D in (2). GAM must be set to the vector (gamma) in (2).
On exit: the rows of C and D and the components of GAM are

re-ordered so that the boundary conditions are in the order:

- (i) conditions on $y(a)$ only;
- (ii) condition involving $y(a)$ and $y(b)$; and
- (iii) conditions on $y(b)$ only.

The routine will be slightly more efficient if the arrays C, D and GAM are ordered in this way before entry, and in this event they will be unchanged on exit.

Note that the problems (1) and (2) must be of boundary value type, that is neither C nor D may be identically zero. Note also that the rank of the matrix [C,D] must be n for the problem to be properly posed. Any violation of these conditions will lead to an error exit.

- 10: MNP -- INTEGER Input
 On entry: the maximum permitted number of mesh points.
 Constraint: MNP \geq 32.
- 11: X(MNP) -- DOUBLE PRECISION array Input/Output
 On entry: if NP \geq 4 (see NP below), the first NP elements must define an initial mesh. Otherwise the elements of x need not be set. Constraint:

$$A = X(1) < X(2) < \dots < X(NP) = B, \text{ for } NP \geq 4. \quad (4)$$
 On exit: $X(1), X(2), \dots, X(NP)$ define the final mesh (with the returned value of NP) satisfying the relation (4).
- 12: Y(N,MNP) -- DOUBLE PRECISION array Output
 On exit: the approximate solution $z(x)$ satisfying (3), on the final mesh, that is

$$Y(j,i) = z_j(x_i), \quad i=1,2,\dots,NP; j=1,2,\dots,n$$
 where NP is the number of points in the final mesh.
 The remaining columns of Y are not used.
- 13: NP -- INTEGER Input/Output
 On entry: determines whether a default mesh or user-supplied mesh is used. If NP = 0, a default value of 4 for NP and a corresponding equispaced mesh $X(1), X(2), \dots, X(NP)$ are used. If NP \geq 4, then the user must define an initial mesh X as in (4) above. On exit: the number of points in the final (returned) mesh.

14: W(LW) -- DOUBLE PRECISION array Workspace

15: LW -- INTEGER Input

On entry: the length of the array W, Constraint:

$$LW \geq MNP \cdot (3N^2 + 5N + 2) + 3N^2 + 5N.$$

16: IW(LIW) -- INTEGER array Workspace

17: LIW -- INTEGER Input

On entry: the length of the array IW. Constraint:

$$LIW \geq MNP \cdot (2N + 1) + N.$$

18: IFAIL -- INTEGER Input/Output

For this routine, the normal use of IFAIL is extended to control the printing of error and warning messages as well as specifying hard or soft failure (see the Essential Introduction).

Before entry, IFAIL must be set to a value with the decimal expansion cba, where each of the decimal digits c, b and a must have a value of 0 or 1.

a=0 specifies hard failure, otherwise soft failure;

b=0 suppresses error messages, otherwise error messages will be printed (see Section 6);

c=0 suppresses warning messages, otherwise warning messages will be printed (see Section 6).

The recommended value for inexperienced users is 110 (i.e., hard failure with all messages printed).

Unless the routine detects an error (see Section 6), IFAIL contains 0 on exit.

6. Error Indicators and Warnings

Errors detected by the routine:

For each error, an explanatory error message is output on the current error message unit (as defined by X04AAF), unless suppressed by the value of IFAIL on entry.

IFAIL= 1

One or more of the parameters N, TOL, NP, MNP, LW or LIW is incorrectly set, B ≤ A or the condition (4) on X is not

satisfied.

IFAIL= 2

There are three possible reasons for this error exit to be taken:

- (i) one of the matrices C or D is identically zero (that is the problem is of initial value and not boundary value type). In this case, IW(1) = 0 on exit;
- (ii) a row of C and the corresponding row of D are identically zero (that is the boundary conditions are rank deficient). In this case, on exit IW(1) contains the index of the first such row encountered; and
- (iii) more than n of the columns of the n by 2n matrix [C,D)] are identically zero (that is the boundary conditions are rank deficient). In this case, on exit IW(1) contains minus the number of non-identically zero columns.

IFAIL= 3

The routine has failed to find a solution to the specified accuracy. There are a variety of possible reasons including:

- (i) the boundary conditions are rank deficient, which may be indicated by the message that the Jacobian is singular. However this is an unlikely explanation for the error exit as all rank deficient boundary conditions should lead instead to error exits with either IFAIL = 2 or IFAIL = 5; see also (iv) below;
- (ii) not enough mesh points are permitted in order to attain the required accuracy. This is indicated by NP = MNP on return from a call to D02GBF. This difficulty may be aggravated by a poor initial choice of mesh points;
- (iii) the accuracy requested cannot be attained on the computer being used; and
- (iv) an unlikely combination of values of F(x) has led to a singular Jacobian. The error should not persist if more mesh points are allowed.

IFAIL= 4

A serious error has occurred in a call to D02GBF. Check all array subscripts and subroutine parameter lists in calls to

D02GBF. Seek expert help.

IFAIL= 5

There are two possible reasons for this error exit which occurs when checking the rank of the boundary conditions by reduction to a row echelon form:

(i) at least one row of the n by $2n$ matrix $[C,D]$ is a linear combination of the other rows and hence the boundary conditions are rank deficient. The index of the first such row encountered is given by $IW(1)$ on exit; and

(ii) as (i) but the rank deficiency implied by this error exit has only been determined up to a numerical tolerance. Minus the index of the first such row encountered is given by $IW(1)$ on exit.

In case (ii) above there is some doubt as to the rank deficiency of the boundary conditions. However even if the boundary conditions are not rank deficient they are not posed in a suitable form for use with this routine.

For example, if

$$C = \begin{pmatrix} 1 & 0 \\ 1 & \epsilon \end{pmatrix}, D = \begin{pmatrix} 1 & 0 \\ 1 & 0 \end{pmatrix}, \text{ (gamma)} = \begin{pmatrix} \text{gamma} \\ 1 \\ 2 \end{pmatrix}$$

and ϵ is small enough, this error exit is likely to be taken. A better form for the boundary conditions in this case would be

$$C = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, D = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, \text{ (gamma)} = \begin{pmatrix} \text{gamma} \\ 1 \\ \epsilon \text{ (gamma)} - \text{gamma} \end{pmatrix}$$

7. Accuracy

The solution returned by the routine will be accurate to the user's tolerance as defined by the relation (3) except in extreme circumstances. If too many points are specified in the initial mesh, the solution may be more accurate than requested and the error may not be approximately equidistributed.

8. Further Comments

The time taken by the routine depends on the difficulty of the

problem, the number of mesh points (and meshes) used and the number of deferred corrections.

The user is strongly recommended to set IFAIL to obtain self-explanatory error messages, and also monitoring information about the course of the computation. The user may select the channel numbers on which this output is to appear by calls of X04AAF (for error messages) or X04ABF (for monitoring information) - see Section 9 for an example. Otherwise the default channel numbers will be used, as specified in the implementation document.

In the case where the user wishes to solve a sequence of similar problems, the use of the final mesh from one case is strongly recommended as the initial mesh for the next.

9. Example

We solve the problem (written as a first order system)

$$(\text{epsilon})y'' + y' = 0$$

with boundary conditions

$$y(0)=0, \quad y(1)=1$$

for the cases $(\text{epsilon})=10^{-1}$ and $(\text{epsilon})=10^{-2}$ using the default initial mesh in the first case, and the final mesh of the first case as initial mesh for the second (more difficult) case. We give the solution and the error at each mesh point to illustrate the accuracy of the method given the accuracy request $\text{TOL}=1.0\text{E}-3$.

Note the call to X04ABF prior to the call to D02GBF.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

D02 -- Ordinary Differential Equations D02KEF
 D02KEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details.
 The symbol (*) after a NAG routine name denotes a routine that is

not included in the Foundation Library.

1. Purpose

D02KEF finds a specified eigenvalue of a regular singular second-order Sturm-Liouville system on a finite or infinite range, using a Pruefer transformation and a shooting method. It also reports values of the eigenfunction and its derivatives. Provision is made for discontinuities in the coefficient functions or their derivatives.

2. Specification

```

SUBROUTINE D02KEF (XPOINT, M, MATCH, COEFFN, BDYVAL, K,
1                 TOL, ELAM, DELAM, HMAX, MAXIT, MAXFUN,
2                 MONIT, REPORT, IFAIL)
  INTEGER          M, MATCH, K, MAXIT, MAXFUN, IFAIL
  DOUBLE PRECISION XPOINT(M), TOL, ELAM, DELAM, HMAX(2,M)
  EXTERNAL         COEFFN, BDYVAL, MONIT, REPORT

```

3. Description

D02KEF has essentially the same purpose as D02KDF(*) with minor modifications to enable values of the eigenfunction to be obtained after convergence to the eigenvalue has been achieved.

~~~~~

It first finds a specified eigenvalue ( $\lambda$ ) of a Sturm-Liouville system defined by a self-adjoint differential equation of the second-order

$$(p(x)y')' + q(x; \lambda)y = 0, \quad a < x < b$$

together with the appropriate boundary conditions at the two (finite or infinite) end-points  $a$  and  $b$ . The functions  $p$  and  $q$ , which are real-valued, must be defined by a subroutine COEFFN. The boundary conditions must be defined by a subroutine BDYVAL, and, in the case of a singularity at  $a$  or  $b$ , take the form of an asymptotic formula for the solution near the relevant end-point.

~~~~~

When the final estimate $\lambda = \lambda$ of the eigenvalue has been found, the routine integrates the differential equation once more with that value of λ , and with initial conditions chosen so that the integral

$$S = \frac{\int_a^b |y(x)|^2 \frac{ddq}{dd(\lambda)}(x;(\lambda)) dx}{\int_a^b \frac{ddq}{dd(\lambda)}(x;(\lambda)) dx}$$

is approximately one. When $q(x;(\lambda))$ is of the form $(\lambda)w(x)+q(x)$, which is the most common case, S represents the square of the norm of y induced by the inner product

$$\langle f, g \rangle = \frac{\int_a^b f(x)g(x)w(x)dx}{\int_a^b w(x)dx},$$

with respect to which the eigenfunctions are mutually orthogonal. This normalisation of y is only approximate, but experience shows that S generally differs from unity by only one or two per cent.

During this final integration the REPORT routine supplied by the user is called at each integration mesh point x . Sufficient information is returned to permit the user to compute $y(x)$ and $y'(x)$ for printing or plotting. For reasons described in Section 8.2, D02KEF passes across to REPORT, not y and y' , but the Pruefer variables (β) , (ϕ) and (ρ) on which the numerical method is based. Their relationship to y and y' is given by the equations

$$p(x)y' = \frac{1}{\sqrt{\beta}} \exp\left(\frac{(\rho)}{2}\right) \cos\left(\frac{(\phi)}{2}\right);$$

$$y = \frac{1}{\sqrt{\beta}} \exp\left(\frac{(\rho)}{2}\right) \sin\left(\frac{(\phi)}{2}\right).$$

For the theoretical basis of the numerical method to be valid, the following conditions should hold on the coefficient functions:

- (a) $p(x)$ must be non-zero and of one sign throughout the interval (a,b) ; and,

- ddq
- (b) ----- must be of one sign throughout (a,b) for all
dd(lambda)
relevant values of (lambda), and must not be identically
zero as x varies, for any (lambda).

Points of discontinuity in the functions p and q or their
derivatives are allowed, and should be included as 'break-points'
in the array XPOINT.

A good account of the theory of Sturm-Liouville systems, with
some description of Pruefer transformations, is given in Birkhoff
and Rota [4], Chapter X. An introduction for the user of Pruefer
transformations for the numerical solution of eigenvalue problems
arising from physics and chemistry is Bailey [2].

The scaled Pruefer method is fairly recent, and is described in a
short note by Pryce [6] and in some detail in the technical
report [5].

5. Parameters

1: XPOINT(M) -- DOUBLE PRECISION array Input

On entry: the points where the boundary conditions computed by BDYVAL are to be imposed, and also any break-points, i.e., XPOINT(1) to XPOINT(m) must contain values x_1, \dots, x_m

such that

$$x_1 \leq x_2 \leq x_3 \leq \dots \leq x_{m-1} \leq x_m$$

with the following meanings:

- (a) x_1 and x_m are the left and right end-points, a and b, of the domain of definition of the Sturm-Liouville system if these are finite. If either a or b is infinite, the corresponding value x_1 or x_m may be a more-or-less arbitrarily 'large' number of appropriate sign.
- (b) x_2 and x_{m-1} are the Boundary Matching Points (BMP's), that is the points at which the left and right boundary conditions computed in BDYVAL are imposed.

If the left-hand end-point is a regular point then the user should set $x_2 = x_1 (=a)$, while if it is a singular point the user must set $x_2 > x_1$. Similarly $x_{m-1} = x_m (=b)$ if the right-hand end-point is regular, and $x_{m-1} < x_m$ if it is singular.

- (c) The remaining $m-4$ points x_3, \dots, x_{m-2} , if any, define 'break-points' which divide the interval $[x_2, x_{m-1}]$ into $m-3$ sub-intervals

$$i = [x_2, x_3], \dots, i_{m-3} = [x_{m-2}, x_{m-1}]$$

Numerical integration of the differential equation is stopped and restarted at each break-point. In simple cases no break-points are needed. However if $p(x)$ or $q(x;(\lambda))$ are given by different formulae in different parts of the range, then integration is more efficient if the range is broken up by break-points in the appropriate way. Similarly points where any jumps occur in $p(x)$ or $q(x;(\lambda))$, or in their

derivatives up to the fifth order, should appear as break-points.

Constraint: $X(1) \leq X(2) < \dots < X(M-1) \leq X(M)$.

2: M -- INTEGER Input
 On entry: the number of points in the array XPOINT.
 Constraint: $M \geq 4$.

3: MATCH -- INTEGER Input/Output
 On entry: MATCH must be set to the index of the 'break-point' to be used as the matching point (see Section 8.3). If MATCH is set to a value outside the range $[2, m-1]$ then a default value is taken, corresponding to the break-point nearest the centre of the interval $[XPOINT(2), XPOINT(m-1)]$.
 On exit: the index of the break-point actually used as the matching point.

4: COEFFN -- SUBROUTINE, supplied by the user. External Procedure
 COEFFN must compute the values of the coefficient functions $p(x)$ and $q(x;(\lambda))$ for given values of x and (λ) .
 Section 3 states conditions which p and q must satisfy.

Its specification is:

```
SUBROUTINE COEFFN (P, Q, DQDL, X, ELAM, JINT)
DOUBLE PRECISION P, Q, DQDL, X, ELAM
INTEGER          JINT
```

1: P -- DOUBLE PRECISION Output
 On exit: the value of $p(x)$ for the current value of x .

2: Q -- DOUBLE PRECISION Output
 On exit: the value of $q(x;(\lambda))$ for the current value of x and the current trial value of (λ) .

3: DQDL -- DOUBLE PRECISION Output
ddq
 On exit: the value of $\frac{ddq}{dd(\lambda)}(x;(\lambda))$ for the current value of x and the current trial value of (λ) . However DQDL is only used in error estimation and an approximation (say to within 20%) will suffice.

4: X -- DOUBLE PRECISION Input
 On entry: the current value of x .

5: ELAM -- DOUBLE PRECISION Input
 On entry: the current trial value of the eigenvalue
 parameter (lambda).

6: JINT -- INTEGER Input
 On entry: the index j of the sub-interval i (see
 j
 specification of XPOINT) in which x lies.
 See Section 8.4 and Section 9 for examples.

COEFFN must be declared as EXTERNAL in the (sub)program
 from which D02KEF is called. Parameters denoted as
 Input must not be changed by this procedure.

5: BDYVAL -- SUBROUTINE, supplied by the user.

External Procedure

BDYVAL must define the boundary conditions. For each end-
 point, BDYVAL must return (in YL or YR) values of $y(x)$ and
 $p(x)y'(x)$ which are consistent with the boundary conditions
 at the end-points; only the ratio of the values matters.
 Here x is a given point (XL or XR) equal to, or close to,
 the end-point.

For a regular end-point (a , say), $x=a$; and a boundary
 condition of the form

$$c_1 y(a) + c_2 y'(a) = 0$$

can be handled by returning constant values in YL, e.g.
 $YL(1)=c_1$ and $YL(2)=-c_2 p(a)$.

For a singular end-point however, YL(1) and YL(2) will in
 general be functions of XL and ELAM, and YR(1) and YR(2)
 functions of XR and ELAM, usually derived analytically from
 a power-series or asymptotic expansion. Examples are given
 in Section 8.5 Section 9.

Its specification is:

```
SUBROUTINE BDYVAL (XL, XR, ELAM, YL, YR)
DOUBLE PRECISION XL, XR, ELAM, YL(3), YR(3)
```

1: XL -- DOUBLE PRECISION Input
 On entry: if a is a regular end-point of the system (so
 that $a=x=x$), then XL contains a . If a is a singular

x_1 x_2
 point (so that $a \leq x_1 < x_2$), then XL contains a point x
 x_1 x_2
 such that $x_1 < x \leq x_2$.
 x_1 x_2

- 2: XR -- DOUBLE PRECISION Input
 On entry: if b is a regular end-point of the system (so that $x_{m-1} = x_m = b$), then XR contains b. If b is a singular point (so that $x_{m-1} < x_m \leq b$), then XR contains a point x such that $x_{m-1} < x \leq x_m$.
- 3: ELAM -- DOUBLE PRECISION Input
 On entry: the current trial value of (lambda).
- 4: YL(3) -- DOUBLE PRECISION array Output
 On exit: YL(1) and YL(2) should contain values of $y(x)$ and $p(x)y'(x)$ respectively (not both zero) which are consistent with the boundary condition at the left-hand end-point, given by $x = XL$. YL(3) should not be set.
- 5: YR(3) -- DOUBLE PRECISION array Output
 On exit: YR(1) and YR(2) should contain values of $y(x)$ and $p(x)y'(x)$ respectively (not both zero) which are consistent with the boundary condition at the right-hand end-point, given by $x = XR$. YR(3) should not be set.

BDYVAL must be declared as EXTERNAL in the (sub)program from which D02KEF is called. Parameters denoted as Input must not be changed by this procedure.

- 6: K -- INTEGER Input
 On entry: the index k of the required eigenvalue when the eigenvalues are ordered
 $(\lambda_0) < (\lambda_1) < (\lambda_2) < \dots < (\lambda_k) < \dots$
 Constraint: $K \geq 0$.
- 7: TOL -- DOUBLE PRECISION Input
 On entry: the tolerance parameter which determines the accuracy of the computed eigenvalue. The error estimate held in DELAM on exit satisfies the mixed absolute/relative error

test

DELAM<=TOL*max(1.0,|ELAM|) (*)

where ELAM is the final estimate of the eigenvalue. DELAM is usually somewhat smaller than the right-hand side of (*) but not several orders of magnitude smaller. Constraint: TOL > 0.0.

8: ELAM -- DOUBLE PRECISION Input/Output

~~~~~

On entry: an initial estimate of the eigenvalue (lambda).  
On exit: the final computed estimate, whether or not an error occurred.

9: DELAM -- DOUBLE PRECISION Input/Output

On entry: an indication of the scale of the problem in the (lambda)-direction. DELAM holds the initial 'search step' (positive or negative). Its value is not critical but the first two trial evaluations are made at ELAM and ELAM + DELAM, so the routine will work most efficiently if the eigenvalue lies between these values. A reasonable choice (if a closer bound is not known) is half the distance between adjacent eigenvalues in the neighbourhood of the one sought. In practice, there will often be a problem, similar to the one in hand but with known eigenvalues, which will help one to choose initial values for ELAM and DELAM.

If DELAM = 0.0 on entry, it is given the default value of 0.25\*max(1.0,|ELAM|). On exit: with IFAIL = 0, DELAM holds an estimate of the absolute error in the computed

~~~~~

eigenvalue, that is $|(lambda)-ELAM| \sim DELAM$. (In Section 8.2 we discuss the assumptions under which this is true.) The true error is rarely more than twice, or less than a tenth, of the estimated error.

With IFAIL /= 0, DELAM may hold an estimate of the error, or its initial value, depending on the value of IFAIL. See Section 6 for further details.

10: HMAX(2,M) -- DOUBLE PRECISION array Input/Output

On entry: HMAX(1,j) a maximum step size to be used by the differential equation code in the jth sub-interval i (as described in the specification of parameter XPOINT), for $j=1,2,\dots,m-3$. If it is zero the routine generates a maximum step size internally.

It is recommended that HMAX(1,j) be set to zero unless the coefficient functions p and q have features (such as a narrow peak) within the jth sub-interval that could be 'missed' if a long step were taken. In such a case HMAX(1,j) should be set to about half the distance over which the feature should be observed. Too small a value will increase the computing time for the routine. See Section 8 for further suggestions.

The rest of the array is used as workspace. On exit: HMAX(1,m-1) and HMAX(1,m) contain the sensitivity coefficients $(\sigma)_1$, $(\sigma)_r$, described in Section 8.6. Other entries contain diagnostic output in case of an error (see Section 6).

- 11: MAXIT -- INTEGER Input/Output
On entry: a bound on n_r , the number of root-finding

iterations allowed, that is the number of trial values of (lambda) that are used. If MAXIT ≤ 0 , no such bound is assumed. (See also under MAXFUN.) Suggested value: MAXIT = 0. On exit: MAXIT will have been decreased by the number of iterations actually performed, whether or not it was positive on entry.

- 12: MAXFUN -- INTEGER Input
On entry: a bound on n_f , the number of calls to COEFFN made

in any one root-finding iteration. If MAXFUN ≤ 0 , no such bound is assumed. Suggested value: MAXFUN = 0.

MAXFUN and MAXIT may be used to limit the computational cost of a call to D02KEF, which is roughly proportional to $n_r n_f$.

- 13: MONIT -- SUBROUTINE, supplied by the user.

External Procedure

MONIT is called by D02KEF at the end of each root-finding iteration and allows the user to monitor the course of the computation by printing out the parameters (see Section 8 for an example).

If no monitoring is required, the dummy subroutine D02KAY may be used. (D02KAY is included in the NAG Foundation Library).

Its specification is:

```

SUBROUTINE MONIT (MAXIT, IFLAG, ELAM, FINFO)
  INTEGER          MAXIT, IFLAG
  DOUBLE PRECISION ELAM, FINFO(15)

```

1: MAXIT -- INTEGER Input
 On entry: the current value of the parameter MAXIT of DO2KEF; this is decreased by one at each iteration.

2: IFLAG -- INTEGER Input
 On entry: IFLAG describes what phase the computation is in, as follows:

IFLAG < 0

an error occurred in the computation of the 'miss-distance' at this iteration;

an error exit from DO2KEF with IFAIL = -IFLAG will follow.

IFLAG = 1

the routine is trying to bracket the eigenvalue
 ~~~~~

(lambda).

IFLAG = 2

the routine is converging to the eigenvalue  
 ~~~~~

(lambda) (having already bracketed it).

3: ELAM -- DOUBLE PRECISION Input
 On entry: the current trial value of (lambda).

4: FINFO(15) -- DOUBLE PRECISION array Input
 On entry: information about the behaviour of the shooting method, and diagnostic information in the case of errors. It should not normally be printed in full if no error has occurred (that is, if IFLAG > 0), though the first few components may be of interest to the user. In case of an error (IFLAG < 0) all the components of FINFO should be printed. The contents of FINFO are as follows:

FINFO(1): the current value of the 'miss-distance' or 'residual' function f((lambda)) on which the shooting

method is based. FINFO(1) is set to zero if IFLAG < 0.

FINFO(2): an estimate of the quantity $dd(\lambda)$ defined as follows. Consider the perturbation in the miss-distance $f(\lambda)$ that would result if the local error, in the solution of the differential equation, were always positive and equal to its maximum permitted value. Then $dd(\lambda)$ is the perturbation in (λ) that would have the same effect on $f(\lambda)$. Thus, at the zero of $f(\lambda)$, $|dd(\lambda)|$ is an approximate bound on the perturbation of the zero (that is the eigenvalue) caused by errors in numerical solution. If $dd(\lambda)$ is very large then it is possible that there has been a programming error in COEFFN such that q is independent of (λ) . If this is the case, an error exit with IFAIL = 5 should follow. FINFO(2) is set to zero if IFLAG < 0.

FINFO(3): the number of internal iterations, using the same value of (λ) and tighter accuracy tolerances, needed to bring the accuracy (that is the value of $dd(\lambda)$) to an acceptable value. Its value should normally be 1.0, and should almost never exceed 2.0.

FINFO(4): the number of calls to COEFFN at this iteration.

FINFO(5): the number of successful steps taken by the internal differential equation solver at this iteration. A step is successful if it is used to advance the integration (cf. COUT(8) in specification of D02PAF(*)).

FINFO(6): the number of unsuccessful steps used by the internal integrator at this iteration (cf. COUT(9) in specification of D02PAF(*)).

FINFO(7): the number of successful steps at the maximum step size taken by the internal integrator at this iteration (cf. COUT(3) in specification of D02PAF(*)).

FINFO(8): is not used.

FINFO(9) to FINFO(15): set to zero, unless IFLAG < 0 in which case they hold the following values describing the point of failure:

FINFO(9): contains the index of the sub-interval where failure occurred, in the range 1 to m-3. In case of an error in BDYVAL, it is set to 0 or m-2 depending on whether the left or right boundary condition caused the error.

FINFO(10): the value of the independent variable x, the point at which error occurred. In case of an error in BDYVAL, it is set to the value of XL or XR as appropriate (see the specification of BDYVAL).

FINFO(11), FINFO(12), FINFO(13): the current values of the Pruefer dependent variables (beta), (phi) and (rho) respectively. These are set to zero in case of an error in BDYVAL.

FINFO(14): the local-error tolerance being used by the internal integrator at the point of failure. This is set to zero in the case of an error in BDYVAL.

FINFO(15): the last integration mesh point. This is set to zero in the case of an error in BDYVAL.

MONIT must be declared as EXTERNAL in the (sub)program from which D02KEF is called. Parameters denoted as Input must not be changed by this procedure.

14: REPORT -- SUBROUTINE, supplied by the user.

External Procedure

This routine provides the means by which the user may compute the eigenfunction $y(x)$ and its derivative at each integration mesh point x . (See Section 8 for an example).

Its specification is:

```
SUBROUTINE REPORT (X, V, JINT)
  INTEGER          JINT
  DOUBLE PRECISION X, V(3)
```

- 1: X -- DOUBLE PRECISION Input
On entry: the current value of the independent variable x . See Section 8.3 for the order in which values of x are supplied.
- 2: V(3) -- DOUBLE PRECISION array Input
On entry: V(1), V(2), V(3) hold the current values of

the Pruefer variables (beta), (phi), (rho) respectively.

3: JINT -- INTEGER Input

On entry: JINT indicates the sub-interval between break-points in which X lies exactly as for the routine COEFFN, except that at the extreme left end-point (when $x = XPOINT(2)$) JINT is set to 0 and at the extreme right end-point (when $x = XPOINT(m-1)$) JINT is set to r

$m-2$.

REPORT must be declared as EXTERNAL in the (sub)program from which D02KEF is called. Parameters denoted as Input must not be changed by this procedure.

15: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

A parameter error. All parameters (except IFAIL) are left unchanged. The reason for the error is shown by the value of HMAX(2,1) as follows:

HMAX(2,1) = 1: $M < 4$;

HMAX(2,1) = 2: $K < 0$;

HMAX(2,1) = 3: $TOL \leq 0.0$;

HMAX(2,1) = 4: XPOINT(1) to XPOINT(m) are not in ascending order.

HMAX(2,2) gives the position i in XPOINT where this was detected.

IFAIL= 2

At some call to BDYVAL, invalid values were returned, that is, either $YL(1) = YL(2) = 0.0$, or $YR(1) = YR(2) = 0.0$ (a

programming error in BDYVAL). See the last call of MONIT for details.

This error exit will also occur if $p(x)$ is zero at the point where the boundary condition is imposed. Probably BDYVAL was called with XL equal to a singular end-point a or with XR equal to a singular end-point b.

IFAIL= 3

At some point between XL and XR the value of $p(x)$ computed by COEFFN became zero or changed sign. See the last call of MONIT for details.

IFAIL= 4

MAXIT > 0 on entry, and after MAXIT iterations the eigenvalue had not been found to the required accuracy.

IFAIL= 5

The 'bracketing' phase (with parameter IFLAG of MONIT equal to 1) failed to bracket the eigenvalue within ten iterations. This is caused by an error in formulating the problem (for example, q is independent of (λ)), or by very poor initial estimates of ELAM, DELAM.

On exit ELAM and ELAM + DELAM give the end-points of the interval within which no eigenvalue was located by the routine.

IFAIL= 6

MAXFUN > 0 on entry, and the last iteration was terminated because more than MAXFUN calls to COEFFN were used. See the last call of MONIT for details.

IFAIL= 7

To obtain the desired accuracy the local error tolerance was set so small at the start of some sub-interval that the differential equation solver could not choose an initial step size large enough to make significant progress. See the last call of MONIT for diagnostics.

IFAIL= 8

At some point inside a sub-interval the step size in the differential equation solver was reduced to a value too small to make significant progress (for the same reasons as with IFAIL = 7). This could be due to pathological behaviour of $p(x)$ and $q(x;(\lambda))$ or to an unreasonable accuracy

requirement or to the current value of (lambda) making the equations 'stiff'. See the last call of MONIT for details.

IFAIL= 9

TOL is too small for the problem being solved and the machine precision is being used. The final value of ELAM should be a very good approximation to the eigenvalue.

IFAIL= 10

C05AZF(*), called by D02KEF, has terminated with the error exit corresponding to a pole of the residual function $f((\lambda))$. This error exit should not occur, but if it does, try solving the problem again with a smaller value for TOL.

IFAIL= 11

A serious error has occurred in an internal call to D02KDY. Check all subroutine calls and array dimensions. Seek expert help.

IFAIL= 12

A serious error has occurred in an internal call to C05AZF(*). Check all subroutine calls and array dimensions. Seek expert help.

HMAX(2,1) holds the failure exit number from the routine where the failure occurred. In the case of a failure in C05AZF(*), HMAX(2,2) holds the value of parameter IND of C05AZF(*).

Note: error exits with IFAIL = 2, 3, 6, 7, 8, 11 are caused by being unable to set up or solve the differential equation at some iteration, and will be immediately preceded by a call of MONIT giving diagnostic information. For other errors, diagnostic information is contained in HMAX(2,j), for $j=1,2,\dots,m$, where appropriate.

7. Accuracy

See the discussion in Section 8.2.

8. Further Comments

8.1. Timing

The time taken by the routine depends on the complexity of the

coefficient functions, whether they or their derivatives are rapidly changing, the tolerance demanded, and how many iterations are needed to obtain convergence. The amount of work per iteration is roughly doubled when TOL is divided by 16. To make the most economical use of the routine, one should try to obtain good initial values for ELAM and DELAM, and, where appropriate, good asymptotic formulae. The boundary matching points should not be set unnecessarily close to singular points. The extra time needed to compute the eigenfunction is principally the cost of one additional integration once the eigenvalue has been found.

8.2. General Description of the Algorithm

A shooting method, for differential equation problems containing unknown parameters, relies on the construction of a 'miss-distance function', which for given trial values of the parameters measures how far the conditions of the problem are from being met. The problem is then reduced to one of finding the values of the parameters for which the miss-distance function is zero, that is to a root-finding process. Shooting methods differ mainly in how the miss-distance is defined.

This routine defines a miss-distance $f(\lambda)$ based on the rotation around the origin of the point $P(x) = (p(x)y'(x), y(x))$ in the Phase Plane as the solution proceeds from a to b . The boundary-conditions define the ray (i.e., two-sided line through the origin) on which $p(x)$ should start, and the ray on which it should finish. The eigenvalue index k defines the total number of half-turns it should make. Numerical solution is actually done by matching point $x=c$. Then $f(\lambda)$ is taken as the angle between the rays to the two resulting points $P_a(c)$ and $P_b(c)$. A relative scaling of the py' and y axes, based on the behaviour of the coefficient functions p and q , is used to improve the numerical behaviour.

Please see figure in printed Reference Manual

The resulting function $f(\lambda)$ is monotonic over -

$-\infty < \lambda < \infty$, increasing if $\frac{ddq}{dd\lambda} > 0$ and decreasing

if $\frac{ddq}{dd\lambda} < 0$, with a unique zero at the desired eigenvalue

```
dd(lambda)
~~~~~
```

(lambda). The routine measures $f((\lambda))$ in units of a half-turn. This means that as (λ) increases, $f((\lambda))$ varies by about 1 as each eigenvalue is passed. (This feature implies that the values of $f((\lambda))$ at successive iterations - especially in the early stages of the iterative process - can be used with suitable extrapolation or interpolation to help the choice of initial estimates for eigenvalues near to the one currently being found.)

The routine actually computes a value for $f((\lambda))$ with errors, arising from the local errors of the differential equation code and from the asymptotic formulae provided by the user if singular points are involved. However, the error estimate output in DELAM is usually fairly realistic, in that the actual

```
~~~~~
error |(lambda)-ELAM| is within an order of magnitude of DELAM.
```

We pass the values of (β) , (ϕ) , (ρ) across through REPORT rather than converting them to values of y , y' inside D02KEF, for the following reasons. First, there may be cases where auxiliary quantities can be more accurately computed from the Pruefer variables than from y and y' . Second, in singular problems on an infinite interval y and y' may underflow towards the end of the range, whereas the Pruefer variables remain well-behaved. Third, with high-order eigenvalues (and therefore highly oscillatory eigenfunctions) the eigenfunction may have a complete oscillation (or more than one oscillation) between two mesh points, so that values of y and y' at mesh points give a very poor representation of the curve. The probable behaviour of the Pruefer variables in this case is that (β) and (ρ) vary slowly whilst (ϕ) increases quickly: for all three Pruefer variables linear interpolation between the values at adjacent mesh points is probably sufficiently accurate to yield acceptable intermediate values of (β) , (ϕ) , (ρ) (and hence of y, y') for graphical purposes.

Similar considerations apply to the exponentially decaying 'tails'. Here (ϕ) has approximately constant value whilst (ρ) increases rapidly in the direction of integration, though the step length is generally fairly small over such a range.

If the solution is output through REPORT at x -values which are too widely spaced, the step length can be controlled by choosing HMAX suitably, or, preferably, by reducing TOL. Both these

choices will lead to more accurate eigenvalues and eigenfunctions but at some computational cost.

8.3. The Position of the Shooting Matching Point c

This point is always one of the values x_i in array XPOINT. It may be specified using the parameter MATCH. The default value is chosen to be the value of that x_i , $2 \leq i \leq m-1$, that lies closest to the middle of the interval $[x_2, x_{m-1}]$. If there is a tie, the rightmost candidate is chosen. In particular if there are no break-points then $c = x_{m-1}$ - that is the shooting is from left to right in this case. A break-point may be inserted purely to move c to an interior point of the interval, even though the form of the equations does not require it. This often speeds up convergence especially with singular problems.

Note that the shooting method used by the code integrates first from the left-hand end x_1 , then from the right-hand end x_r , to meet at the matching point c in the middle. This will of course be reflected in printed or graphical output. The diagram shows a possible sequence of nine mesh points (τ) through (τ) in the order in which they appear, assuming there are just two sub-intervals (so $m=5$).

Figure 1

Please see figure in printed Reference Manual

Since the shooting method usually fails to match up the two 'legs $p(x)y'$ ' or both, at the matching point c . The code in fact 'shares large jump does not imply an inaccurate eigenvalue, but implies either

- (a) a badly chosen matching point: if $q(x;(\lambda))$ has a 'humped' shape, c should be chosen near the maximum value of q , especially if q is negative at the ends of the interval.
- (b) An inherently ill-conditioned problem, typically one where another eigenvalue is pathologically close to the one being sought. In this case it is extremely difficult to obtain an

accurate eigenfunction.

In Section 9 below, we find the 11th eigenvalue and corresponding eigenfunction of the equation

$$y'' + ((\lambda) - x - 2/x)y = 0 \quad \text{on } 0 < x < \infty$$

the boundary conditions being that y should remain bounded as x tends to 0 and x tends to ∞ . The coding of this problem is discussed in detail in Section 8.5.

The choice of matching point c is open. If we choose $c=30.0$ as in the D02KDF(*) example program we find that the exponentially increasing component of the solution dominates and we get extremely inaccurate values for the eigenfunction (though the eigenvalue is determined accurately). The values of the eigenfunction calculated with $c=30.0$ are given schematically in Figure 2.

Figure 2

Please see figure in printed Reference Manual

If we choose c as the maximum of the hump in $q(x;(\lambda))$ (see (a) above) we instead obtain the accurate results given in Figure 3.

Figure 3

Please see figure in printed Reference Manual

8.4. Examples of Coding the COEFFN Routine

Coding COEFFN is straightforward except when break-points are needed. The examples below show:

- (a) a simple case,
- (b) a case in which discontinuities in the coefficient functions or their derivatives necessitate break-points, and
- (c) a case where break-points together with the HMAX parameter are an efficient way to deal with a coefficient function that is well-behaved except over one short interval.

Example A

The modified Bessel equation

$$x(xy')' + ((\lambda)x^2 - (\nu)^2)y = 0$$

Assuming the interval of solution does not contain the origin, dividing through by x , we have $p(x) = x$,

$q(x;(\lambda)) = (\lambda)x - (\nu)^2/x$. The code could be

```
SUBROUTINE COEFFN(P,Q,DQDL,X,ELAM,JINT)
P = X
Q = ELAM*X + NU*NU/X
DQDL = X
RETURN
END
```

where NU (standing for (ν)) is a real variable that might be defined in a DATA statement, or might be in user-declared COMMON so that its value could be set in the main program.

Example B

The Schroedinger equation

$$y'' + ((\lambda) + q(x))y = 0$$

$\begin{cases} 2 \\ \{x \mid -10 \leq x \leq 10\}, \\ \text{where } q(x) = \begin{cases} 6/x^2 & (|x| > 4), \end{cases} \end{cases}$

over some interval 'approximating to $(-\infty, \infty)$ ', say $[-20, 20]$. Here we need break-points at ± 4 , forming three sub-intervals $i_1 = [-20, -4]$, $i_2 = [-4, 4]$, $i_3 = [4, 20]$. The code could be

```
1
2
3
SUBROUTINE COEFFN(P,Q,DQDL,X,ELAM,JINT)
IF (JINT.EQ.2) THEN
Q = ELAM + X*X - 10.0E0
ELSE
```

```

      Q = ELAM + 6.0E0/ABS(X)
    ENDIF
    P = 1.0E0
    DQDL = 1.0E0
    RETURN
  END

```

The array XPOINT would contain the values $x_1, -20.0, -4.0, +4.0, +20.0, x_6$ and m would be 6. The choice of appropriate values for x_1 and x_6 depends on the form of the asymptotic formula computed by BDYVAL and the technique is discussed in the next subsection.

Example C

$$y'' + (\lambda)(1 - 2e^{-100x^2})y = 0, \text{ over } -10 \leq x \leq 10$$

Here $q(x;(\lambda))$ is nearly constant over the range except for a sharp inverted spike over approximately $-0.1 \leq x \leq 0.1$. There is a danger that the routine will build up to a large step size and 'step over' the spike without noticing it. By using break-points - say at ± 0.5 - one can restrict the step size near the spike without impairing the efficiency elsewhere.

The code for COEFFN could be

```

SUBROUTINE COEFFN(P,Q,DQDL,X,ELAM,JINT)
  P = 1.0E0
  DQDL = 1.0E0 - 2.0E0*EXP(-100.0E0*X*X)
  Q = ELAM*DQDL
  RETURN
END

```

XPOINT might contain $-0.0, -10.0, -0.5, 0.5, 10.0, 10.0$ (assuming ± 10 are regular points) and m would be 6. HMAX(1,j), $j=1,2,3$ might contain $0.0, 0.1$ and 0.0 .

8.5. Examples of Boundary Conditions at Singular Points

Quoting from Bailey [2] page 243: 'Usually... the differential equation has two essentially different types of solution near a singular point, and the boundary condition there merely serves to distinguish one kind from the other. This is the case in all the standard examples of mathematical physics.'

In most cases the behaviour of the ratio $p(x)y'/y$ near the point is quite different for the two types of solution. Essentially what the user provides through his BDYVAL routine is an approximation to this ratio, valid as x tends to the singular point (SP).

The user must decide (a) how accurate to make this approximation or asymptotic formula, for example how many terms of a series to use, and (b) where to place the boundary matching point (BMP) at which the numerical solution of the differential equation takes over from the asymptotic formula. Taking the BMP closer to the SP will generally improve the accuracy of the asymptotic formula, but will make the computation more expensive as the Pruefer differential equations generally become progressively more ill-behaved as the SP is approached. The user is strongly recommended to experiment with placing the BMPs. In many singular problems quite crude asymptotic formulae will do. To help the user avoid needlessly accurate formulae, D02KEF outputs two 'sensitivity coefficients' (σ_l) , (σ_r) which estimate how much the errors at the BMP's affect the computed eigenvalue. They are described in detail below, see Section 8.6.

Example of coding BDYVAL:

The example below illustrates typical situations:

$$y'' + ((\lambda - x - \frac{2}{x}))y = 0, \text{ for } 0 < x < \infty$$

the boundary conditions being that y should remain bounded as x tends to 0 and x tends to ∞ .

At the end $x=0$ there is one solution that behaves like x^2 and another that behaves like x^{-1} . For the first of these solutions

$p(x)y'/y$ is asymptotically $2/x$ while for the second it is asymptotically $-1/x$. Thus the desired ratio is specified by setting

$$YL(1)=x \text{ and } YL(2)=2.0.$$

At the end $x=\infty$ the equation behaves like Airy's equation shifted through (λ) , i.e., like $y''-ty=0$ where $t=x-(\lambda)$, so again there are two types of solution. The solution we require behaves as

$$\frac{\exp(-t^{3/2})}{t^{3/2}}$$

and the other as

$$\frac{\exp(+t^{3/2})}{t^{3/2}}$$

once, the desired solution has $p(x)y'/y \sim -\sqrt{t}$ so that we could set

$YR(1) = 1.0$ and $YR(2) = -\sqrt{x-(\lambda)}$. The complete subroutine might thus be

```
SUBROUTINE BDYVAL(XL,XR,ELAM,YL,YR)
  real XL, XR, ELAM, YL(3), YR(3)
  YL(1) = XL
  YL(2) = 2.0E0
  YR(1) = 1.0E0
  YR(2) = -SQRT(XR - ELAM)
  RETURN
END
```

Clearly for this problem it is essential that any value given by D02KEF to XR is well to the right of the value of ELAM, so that the user must vary the right-hand BMP with the eigenvalue index k function $A_i(x)$, so there is no problem in estimating ELAM.

More accurate asymptotic formulae are easily found - near $x=0$ by the standard Frobenius method, and near $x=\infty$ by using standard

asymptotics for $A_i(x)$, $A_i'(x)$ (see [1], p. 448). For example, by the Frobenius method the solution near $x=0$ has the expansion

$$y = x^2 (c_0 + c_1 x + c_2 x^2 + \dots)$$

with

$$c_0 = 1, c_1 = 0, c_2 = -\frac{(\lambda)}{10}, c_3 = \frac{1}{3}, \dots, c_n = \frac{c_{n-3} - (\lambda)c_{n-2}}{n(n+3)}$$

This yields

$$\frac{p(x)y'}{y} = \frac{2 - (\lambda)x^2 + \dots}{x(1 - \frac{(\lambda)}{10}x^2 + \dots)}$$

8.6. The Sensitivity Parameters $(\sigma)_l$ and $(\sigma)_r$

The sensitivity parameters $(\sigma)_l, (\sigma)_r$ (held in HMAX(1,m-1) and HMAX(1,m) on output) estimate the effect of errors in the boundary conditions. For sufficiently small errors $(\Delta)y$, $(\Delta)py'$ in y and py' respectively, the relations

$$(\Delta)(\lambda)_l \sim (y \cdot (\Delta)py' - py' \cdot (\Delta)y) (\sigma)_l$$

$$(\Delta)(\lambda)_r \sim (y \cdot (\Delta)py' - py' \cdot (\Delta)y) (\sigma)_r$$

are satisfied where the subscripts l, r denote errors committed at left- and right-hand BMP's respectively, and $(\Delta)(\lambda)$ denotes the consequent error in the computed eigenvalue.

8.7. Missed Zeros

This is a pitfall to beware of at a singular point. If the BMP is

chosen so far from the SP that a zero of the desired eigenfunction lies in between them, then the routine will fail to number of zeros of its eigenfunction, the result will be that:

- (a) The wrong eigenvalue will be computed for the given index k
 - in fact some $(\lambda_{k+k'})$ will be found where $k' \geq 1$.
- (b) The same index k can cause convergence to any of several eigenvalues depending on the initial values of ELAM and DELAM.

It is up to the user to take suitable precautions - for instance by varying the position of the BMP's in the light of his knowledge of the asymptotic behaviour of the eigenfunction at different eigenvalues.

9. Example

To find the 11th eigenvalue and eigenfunction of the example of Section 8.5, using the simple asymptotic formulae for the boundary conditions.

Comparison of the results from this example program with the corresponding results from D02KDF(*) example program shows that similar output is produced from the routine MONIT, followed by the eigenfunction values from REPORT, and then a further line of information from MONIT (corresponding to the integration to find the eigenfunction). Final information is printed within the example program exactly as with D02KDF(*).

Note the discrepancy at the matching point $c = \sqrt{4}$, the maximum of $q(x;(\lambda_{k+k'}))$, in this case) between the solutions obtained by integrations from left and right end-points.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

D02 -- Ordinary Differential Equations D02RAF
 D02RAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for

your implementation to check implementation-dependent details. The symbol (*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

1. Purpose

D02RAF solves the two-point boundary-value problem with general boundary conditions for a system of ordinary differential equations, using a deferred correction technique and Newton iteration.

2. Specification

```

SUBROUTINE D02RAF (N, MNP, NP, NUMBEG, NUMMIX, TOL, INIT,
1                X, Y, IY, ABT, FCN, G, IJAC, JACOB,
2                JACOBG, DELEPS, JACEPS, JACGEP, WORK,
3                LWORK, IWORK, LIWORK, IFAIL)
  INTEGER        N, MNP, NP, NUMBEG, NUMMIX, INIT, IY,
1                IJAC, LWORK, IWORK(LIWORK), LIWORK, IFAIL
  DOUBLE PRECISION TOL, X(MNP), Y(IY,MNP), ABT(N), DELEPS,
1                WORK(LWORK)
  EXTERNAL       FCN, G, JACOB, JACOBG, JACEPS, JACGEP

```

3. Description

D02RAF solves a two-point boundary-value problem for a system of n ordinary differential equations in the interval (a,b) with $b>a$. The system is written in the form

$$y'_i = f_i(x, y_1, y_2, \dots, y_n), \quad i=1, 2, \dots, n \quad (1)$$

and the derivatives f_i are evaluated by a subroutine FCN supplied by the user. With the differential equations (1) must be given a system of n (nonlinear) boundary conditions

$$g_i(y(a), y(b)) = 0, \quad i=1, 2, \dots, n$$

where

$$y(x) = [y_1(x), y_2(x), \dots, y_n(x)]^T. \quad (2)$$

The functions g_i are evaluated by a subroutine G supplied by the user. The solution is computed using a finite-difference technique with deferred correction allied to a Newton iteration to solve the finite-difference equations. The technique used is described fully in Pereyra [1].

The user must supply an absolute error tolerance and may also supply an initial mesh for the finite-difference equations and an initial approximate solution (alternatively a default mesh and approximation are used). The approximate solution is corrected using Newton iteration and deferred correction. Then, additional points are added to the mesh and the solution is recomputed with the aim of making the error everywhere less than the user's tolerance and of approximately equidistributing the error on the final mesh. The solution is returned on this final mesh.

If the solution is required at a few specific points then these should be included in the initial mesh. If, on the other hand, the solution is required at several specific points then the user should use the interpolation routines provided in Chapter E01 if these points do not themselves form a convenient mesh.

The Newton iteration requires Jacobian matrices

$$\begin{pmatrix} ddf \\ i \end{pmatrix} \begin{pmatrix} ddg \\ i \end{pmatrix} \begin{pmatrix} ddg \\ i \end{pmatrix} \\ \begin{pmatrix} ---- \end{pmatrix}, \begin{pmatrix} ----- \end{pmatrix} \text{ and } \begin{pmatrix} ----- \end{pmatrix}. \\ \begin{pmatrix} ddy \\ j \end{pmatrix} \begin{pmatrix} ddy(a) \\ j \end{pmatrix} \begin{pmatrix} ddy(b) \\ j \end{pmatrix}$$

These may be supplied by the user through subroutines JACOB F for $\begin{pmatrix} ddf \\ i \end{pmatrix}$ $\begin{pmatrix} ddg \\ i \end{pmatrix}$ $\begin{pmatrix} ddg \\ i \end{pmatrix}$ $\begin{pmatrix} ---- \end{pmatrix}$ and JACOB G for the others. Alternatively the Jacobians $\begin{pmatrix} ddy \\ j \end{pmatrix}$ $\begin{pmatrix} ddy(a) \\ j \end{pmatrix}$ $\begin{pmatrix} ddy(b) \\ j \end{pmatrix}$

may be calculated by numerical differentiation using the algorithm described in Curtis et al [2].

For problems of the type (1) and (2) for which it is difficult to determine an initial approximation from which the Newton iteration will converge, a continuation facility is provided. The user must set up a family of problems

$$y' = f(x, y, (\epsilon)), \quad g(y(a), y(b), (\epsilon)) = 0, \quad (3)$$

where $f = [f_1, f_2, \dots, f_n]^T$ etc, and where (ϵ) is a continuation parameter. The choice $(\epsilon)=0$ must give a problem (3) which is easy to solve and $(\epsilon)=1$ must define the problem whose solution is actually required. The routine solves a sequence of problems with (ϵ) values

$$0 = (\epsilon)_1 < (\epsilon)_2 < \dots < (\epsilon)_p = 1. \quad (4)$$

The number p and the values $(\epsilon)_i$ are chosen by the routine so that each problem can be solved using the solution of its predecessor as a starting approximation. Jacobians $\frac{ddf}{dd(\epsilon)}$ and $\frac{ddg}{dd(\epsilon)}$ are required and they may be supplied by the user via routines JACEPS and JACGEP respectively or may be computed by numerical differentiation.

5. Parameters

- 1: N -- INTEGER Input
On entry: the number of differential equations, n .
Constraint: $N > 0$.
- 2: MNP -- INTEGER Input
On entry: MNP must be set to the maximum permitted number of points in the finite-difference mesh. If LWORK or LIWORK

(see below) is too small then internally MNP will be replaced by the maximum permitted by these values. (A warning message will be output if on entry IFAIL is set to obtain monitoring information.) Constraint: MNP \geq 32.

- 3: NP -- INTEGER Input/Output
 On entry: NP must be set to the number of points to be used in the initial mesh. Constraint: $4 \leq NP \leq MNP$. On exit: the number of points in the final mesh.

- 4: NUMBEG -- INTEGER Input
 On entry: the number of left-hand boundary conditions (that is the number involving $y(a)$ only). Constraint: $0 \leq \text{NUMBEG} < N$.

- 5: NUMMIX -- INTEGER Input
 On entry: the number of coupled boundary conditions (that is the number involving both $y(a)$ and $y(b)$). Constraint: $0 \leq \text{NUMMIX} \leq N - \text{NUMBEG}$.

- 6: TOL -- DOUBLE PRECISION Input
 On entry: a positive absolute error tolerance. If

$$a = x_1 < x_2 < \dots < x_{NP} = b$$
 is the final mesh, $z_j(x_i)$ is the j th component of the approximate solution at x_i , and $y_j(x_i)$ is the j th component of the true solution of (1) and (2), then, except in extreme circumstances, it is expected that

$$|z_j(x_i) - y_j(x_i)| \leq \text{TOL}, \quad i=1,2,\dots,NP; \quad j=1,2,\dots,n. \quad (5)$$
 Constraint: TOL $>$ 0.0.

- 7: INIT -- INTEGER Input
 On entry: indicates whether the user wishes to supply an initial mesh and approximate solution (INIT \neq 0) or whether default values are to be used, (INIT = 0).

- 8: X(MNP) -- DOUBLE PRECISION array Input/Output
 On entry: the user must set $X(1) = a$ and $X(NP) = b$. If INIT = 0 on entry a default equispaced mesh will be used, otherwise the user must specify a mesh by setting $X(i) = x_i$,
 for $i = 2, 3, \dots, NP-1$. Constraints:
 $X(1) < X(NP)$, if INIT = 0,

$X(1) < X(2) < \dots < X(NP)$, if $INIT \neq 0$.

On exit: $X(1), X(2), \dots, X(NP)$ define the final mesh (with the returned value of NP) and $X(1) = a$ and $X(NP) = b$.

- 9: $Y(IY, MNP)$ -- DOUBLE PRECISION array Input/Output
 On entry: if $INIT = 0$, then Y need not be set.

If $INIT \neq 0$, then the array Y must contain an initial approximation to the solution such that $Y(j, i)$ contains an approximation to

$$y_j(x_i), \quad i=1, 2, \dots, NP; \quad j=1, 2, \dots, n.$$

On exit: the approximate solution $z_j(x_i)$ satisfying (5) on

the final mesh, that is

$$Y(j, i) = z_j(x_i), \quad i=1, 2, \dots, NP; \quad j=1, 2, \dots, n,$$

where NP is the number of points in the final mesh. If an error has occurred then Y contains the latest approximation to the solution. The remaining columns of Y are not used.

- 10: IY -- INTEGER Input
 On entry:
 the first dimension of the array Y as declared in the (sub)program from which $D02RAF$ is called.
 Constraint: $IY \geq N$.

- 11: $ABT(N)$ -- DOUBLE PRECISION array Output
 On exit: $ABT(i)$, for $i=1, 2, \dots, n$, holds the largest estimated error (in magnitude) of the i th component of the solution over all mesh points.

- 12: FCN -- SUBROUTINE, supplied by the user. External Procedure
 FCN must evaluate the functions f_i (i.e., the derivatives y'_i) at a general point x for a given value of (epsilon), the continuation parameter (see Section 3).

Its specification is:

```
SUBROUTINE FCN (X, EPS, Y, F, N)
  INTEGER      N
  DOUBLE PRECISION X, EPS, Y(N), F(N)
```

- 1: X -- DOUBLE PRECISION Input
On entry: the value of the argument x.
 - 2: EPS -- DOUBLE PRECISION Input
On entry: the value of the continuation parameter,
(epsilon). This is 1 if continuation is not being used.
 - 3: Y(N) -- DOUBLE PRECISION array Input
On entry: the value of the argument y , for

i

i=1,2,...,n.
 - 4: F(N) -- DOUBLE PRECISION array Output
On exit: the values of f , for i=1,2,...,n.

i
 - 5: N -- INTEGER Input
On entry: the number of equations.
FCN must be declared as EXTERNAL in the (sub)program
from which D02RAF is called. Parameters denoted as
Input must not be changed by this procedure.
- 13: G -- SUBROUTINE, supplied by the user. External Procedure
G must evaluate the boundary conditions in equation (3) and
place them in the array BC.
- Its specification is:
- ```
SUBROUTINE G (EPS, YA, YB, BC, N)
 INTEGER N
 DOUBLE PRECISION EPS, YA(N), YB(N), BC(N)
```
- 1: EPS -- DOUBLE PRECISION Input  
On entry: the value of the continuation parameter,  
(epsilon). This is 1 if continuation is not being used.
  - 2: YA(N) -- DOUBLE PRECISION array Input  
On entry: the value y (a), for i=1,2,...,n.  

i
  - 3: YB(N) -- DOUBLE PRECISION array Input  
On entry: the value y (b), for i=1,2,...,n.  

i

4: BC(N) -- DOUBLE PRECISION array Output  
 On exit: the values  $g(y(a), y(b), (\epsilon))$ , for  
 $i$   
 $i=1, 2, \dots, n$ . These must be ordered as follows:  
 (i) first, the conditions involving only  $y(a)$  (see  
 NUMBEG description above);  
 (ii) next, the NUMMIX coupled conditions involving  
 both  $y(a)$  and  $y(b)$  (see NUMMIX description  
 above); and,  
 (iii) finally, the conditions involving only  $y(b)$  (N-  
 NUMBEG-NUMMIX).

5: N -- INTEGER Input  
 On entry: the number of equations,  $n$ .  
 G must be declared as EXTERNAL in the (sub)program from  
 which D02RAF is called. Parameters denoted as Input  
 must not be changed by this procedure.

14: IJAC -- INTEGER Input  
 On entry: indicates whether or not the user is supplying  
 Jacobian evaluation routines. If IJAC  $\neq 0$  then the user  
 must supply routines JACOBF and JACOBG and also, when  
 continuation is used, routines JACEPS and JACGEP. If IJAC =  
 0 numerical differentiation is used to calculate the  
 Jacobian and the routines D02GAZ, D02GAY, D02GAZ and D02GAX  
 $(\text{ddf})$   
 $(i)$   
 JACOBF must evaluate the Jacobian  $(\text{---})$  for  $i, j=1, 2, \dots, n$ ,  
 $(\text{ddy})$   
 $(j)$   
 given  $x$  and  $y$ , for  $j=1, 2, \dots, n$ .  
 $j$

Its specification is:

```
SUBROUTINE JACOBF (X, EPS, Y, F, N)
 INTEGER N
 DOUBLE PRECISION X, EPS, Y(N), F(N,N)
```

1: X -- DOUBLE PRECISION Input  
 On entry: the value of the argument  $x$ .

2: EPS -- DOUBLE PRECISION Input  
 On entry: the value of the continuation parameter

(epsilon). This is 1 if continuation is not being used.

```

3: Y(N) -- DOUBLE PRECISION array Input
 On entry: the value of the argument y , for
 i
 i=1,2,...,n.

```

```

4: F(N,N) -- DOUBLE PRECISION array Output
 ddf
 i
On exit: F(i,j) must be set to the value of ----,
 ddy
 j
evaluated at the point (x,y), for i,j=1,2,...,n.

```

```

5: N -- INTEGER Input
 On entry: the number of equations, n.
JACBOF must be declared as EXTERNAL in the (sub)program
from which D02RAF is called. Parameters denoted as
Input must not be changed by this procedure.

```

```
16: JACOBG -- SUBROUTINE, supplied by the user.
```

|                                    |                    |               |
|------------------------------------|--------------------|---------------|
|                                    | External Procedure |               |
|                                    | ( ddg )            | ( ddg )       |
|                                    | ( i )              | ( i )         |
| JACOBI must evaluate the Jacobians | ( ----- )          | and ( ----- ) |
|                                    | ( ddy (a) )        | ( ddy (b) )   |
|                                    | ( j )              | ( j )         |

The ordering of the rows of AJ and BJ must correspond to the ordering of the boundary conditions described in the specification of subroutine G above.

Its specification is:

```

SUBROUTINE JACOBG (EPS, YA, YB, AJ, BJ, N)
 INTEGER N
 DOUBLE PRECISION EPS, YA(N), YB(N), AJ(N,N), BJ
1 (N,N)

```

```

1: EPS -- DOUBLE PRECISION Input
 On entry: the value of the continuation parameter,
 (epsilon). This is 1 if continuation is not being used.

```

```

2: YA(N) -- DOUBLE PRECISION array Input
 On entry: the value y (a), for i=1,2,...,n.
 i

```

- 3: YB(N) -- DOUBLE PRECISION array Input  
 On entry: the value  $y(b)_i$ , for  $i=1,2,\dots,n$ .
- 4: AJ(N,N) -- DOUBLE PRECISION array Output  
 $ddg_i$   
 On exit: AJ(i,j) must be set to the value  $-----$ ,  
 $ddy(a)_j$   
 for  $i,j=1,2,\dots,n$ .
- 5: BJ(N,N) -- DOUBLE PRECISION array Output  
 $ddg_i$   
 On exit: BJ(i,j) must be set to the value  $-----$ ,  
 $ddy(b)_j$   
 for  $i,j=1,2,\dots,n$ .
- 6: N -- INTEGER Input  
 On entry: the number of equations, n.  
 JACOBG must be declared as EXTERNAL in the (sub)program  
 from which D02RAF is called. Parameters denoted as  
 Input must not be changed by this procedure.
- 17: DELEPS -- DOUBLE PRECISION Input/Output  
 On entry: DELEPS must be given a value which specifies  
 whether continuation is required. If  $DELEPS \leq 0.0$  or  $DELEPS \geq 1.0$   
 then it is assumed that continuation is not required.  
 If  $0.0 < DELEPS < 1.0$  then it is assumed that continuation  
 is required unless  $DELEPS < \text{square root of machine precision}$   
 when an error exit is taken. DELEPS is used as the increment  
 $(\epsilon)^2 - (\epsilon)$  (see (4)) and the choice  $DELEPS = 0.1$   
 $1$   
 is recommended. On exit: an overestimate of the increment  
 $(\epsilon)^2 - (\epsilon)$  (in fact the value of the increment  
 $p - p^{-1}$   
 which would have been tried if the restriction  $(\epsilon) = 1$   
 $p$   
 had not been imposed). If continuation was not requested  
 then  $DELEPS = 0.0$ .
- If continuation is not requested then the parameters JACEPS  
 and JACGEP may be replaced by dummy actual parameters in the

call to D02RAF. (D02GAZ and D02GAX respectively may be used as the dummy parameters.)

18: JACEPS -- SUBROUTINE, supplied by the user.

External Procedure  
ddf  
i

JACEPS must evaluate the derivative ----- given x and  
dd(epsilon)  
y if continuation is being used.

Its specification is:

SUBROUTINE JACEPS (X, EPS, Y, F, N)  
INTEGER N  
DOUBLE PRECISION X, EPS, Y(N), F(N)

1: X -- DOUBLE PRECISION Input  
On entry: the value of the argument x.

2: EPS -- DOUBLE PRECISION Input  
On entry: the value of the continuation parameter,  
(epsilon).

3: Y(N) -- DOUBLE PRECISION array Input  
On entry: the solution values y at the point x, for  
i  
i=1,2,...,n.

4: F(N) -- DOUBLE PRECISION array Output  
ddf  
i  
On exit: F(i) must contain the value ----- at  
dd(epsilon)  
the point (x,y), for i=1,2,...,n.

5: N -- INTEGER Input  
On entry: the number of equations, n.  
JACEPS must be declared as EXTERNAL in the (sub)program  
from which D02RAF is called. Parameters denoted as  
Input must not be changed by this procedure.

19: JACGEP -- SUBROUTINE, supplied by the user.

External Procedure  
ddg  
i

Its specification is:

```

20: WORK(LWORK) -- DOUBLE PRECISION array Workspace
21: LWORK -- INTEGER Input
 On entry:
 the dimension of the array WORK as declared in the
 (sub)program from which D02RAF is called.
 2 2
 Constraint: LWORK>=MNP*(3N +6N+2)+4N +3N.
22: IWORK(LIWORK) -- INTEGER array Workspace

```

23: LIWORK -- INTEGER Input

On entry:

the dimension of the array IWORK as declared in the  
(sub)program from which D02RAF is called.

Constraints:

$LIWORK \geq MNP \cdot (2 \cdot N + 1) + N$ , if  $IJAC \neq 0$ ,

2

$LIWORK \geq MNP \cdot (2 \cdot N + 1) + N + 4 \cdot N + 2$ , if  $IJAC = 0$ .

24: IFAIL -- INTEGER Input/Output

For this routine, the normal use of IFAIL is extended to  
control the printing of error and warning messages as well  
as specifying hard or soft failure (see the Essential  
Introduction).

Before entry, IFAIL must be set to a value with the decimal  
expansion cba, where each of the decimal digits c, b and a  
must have a value of 0 or 1.

a=0 specifies hard failure, otherwise soft failure;

b=0 suppresses error messages, otherwise error messages  
will be printed (see Section 6);

c=0 suppresses warning messages, otherwise warning  
messages will be printed (see Section 6).

The recommended value for inexperienced users is 110 (i.e.,  
hard failure with all messages printed).

Unless the routine detects an error (see Section 6), IFAIL  
contains 0 on exit.

## 6. Error Indicators and Warnings

Errors detected by the routine:

For each error, an explanatory error message is output on the  
current error message unit (as defined by X04AAF), unless  
suppressed by the value of IFAIL on entry.

IFAIL= 1

One or more of the parameters N, MNP, NP, NUMBEG, NUMMIX,  
TOL, DELEPS, LWORK or LIWORK has been incorrectly set, or  $X(1) \geq X(NP)$  or the mesh points  $X(i)$  are not in strictly  
ascending order.

## IFAIL= 2

A finer mesh is required for the accuracy requested; that is MNP is not large enough. This error exit normally occurs when the problem being solved is difficult (for example, there is a boundary layer) and high accuracy is requested. A poor initial choice of mesh points will make this error exit more likely.

## IFAIL= 3

The Newton iteration has failed to converge. There are several possible causes for this error:

- (i) faulty coding in one of the Jacobian calculation routines;
- (ii) if  $IJAC = 0$  then inaccurate Jacobians may have been calculated numerically (this is a very unlikely cause); or,
- (iii) a poor initial mesh or initial approximate solution has been selected either by the user or by default or there are not enough points in the initial mesh. Possibly, the user should try the continuation facility.

## IFAIL= 4

The Newton iteration has reached round-off error level. It could be however that the answer returned is satisfactory. The error is likely to occur if too high an accuracy is requested.

## IFAIL= 5

The Jacobian calculated by JACOBG (or the equivalent matrix calculated by numerical differentiation) is singular. This may occur due to faulty coding of JACOBG or, in some circumstances, to a zero initial choice of approximate solution (such as is chosen when  $INIT = 0$ ).

## IFAIL= 6

There is no dependence on (epsilon) when continuation is being used. This can be due to faulty coding of JACEPS or JACGEP or, in some circumstances, to a zero initial choice of approximate solution (such as is chosen when  $INIT = 0$ ).

## IFAIL= 7

DELEPS is required to be less than machine precision for continuation to proceed. It is likely that either the

problem (3) has no solution for some value near the current value of (epsilon) (see the advisory print out from D02RAF) or that the problem is so difficult that even with continuation it is unlikely to be solved using this routine. If the latter cause is suspected then using more mesh points initially may help.

IFAIL= 8

Indicates that a serious error has occurred in a call to D02RAF. Check all array subscripts and subroutine parameter lists in calls to D02RAF. Seek expert help.

IFAIL= 9

Indicates that a serious error has occurred in a call to D02RAR. Check all array subscripts and subroutine parameter lists in calls to D02RAF. Seek expert help.

## 7. Accuracy

The solution returned by the routine will be accurate to the user's tolerance as defined by the relation (5) except in extreme circumstances. The final error estimate over the whole mesh for each component is given in the array ABT. If too many points are specified in the initial mesh, the solution may be more accurate than requested and the error may not be approximately equidistributed.

## 8. Further Comments

There are too many factors present to quantify the timing. The time taken by the routine is negligible only on very simple problems.

The user is strongly recommended to set IFAIL to obtain self-explanatory error messages, and also monitoring information about the course of the computation.

In the case where the user wishes to solve a sequence of similar problems, the use of the final mesh and solution from one case as the initial mesh is strongly recommended for the next.

## 9. Example

We solve the differential equation

$$y''' = -yy'' - 2(\epsilon)(1-y')$$

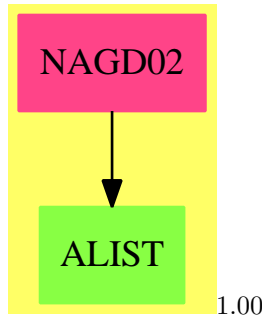

with  $(\epsilon)=1$  and boundary conditions

$$y(0)=y'(0)=0, \quad y'(10)=1$$

to an accuracy specified by  $TOL=1.0E-4$ . The continuation facility is used with the continuation parameter  $(\epsilon)$  introduced as in the differential equation above and with  $DELEPS = 0.1$  initially. (The continuation facility is not needed for this problem and is used here for illustration.)

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

D03 -- Partial Differential Equations                  Introduction -- D03  
Chapter D03  
Partial Differential Equations

This chapter is concerned with the solution of partial differential equations.

The definition of a partial differential equation problem includes not only the equation itself but also the domain of interest and appropriate subsidiary conditions. Indeed, partial differential equations are usually classified as elliptic, hyperbolic or parabolic according to the form of the equation and the form of the subsidiary conditions which must be assigned to produce a well-posed problem. Ultimately it is hoped that this chapter will contain routines for the solution of equations of each of these types together with automatic mesh generation routines and other utility routines particular to the solution of partial differential equations. The routines in this chapter will often call upon routines from the Linear Algebra Chapter F04 -- Simultaneous Linear Equations.

$$au_{xx} + 2bu_{xy} + cu_{yy} + du_x + eu_y + fu + g = 0, \quad (1)$$

Equation (1) is called elliptic, hyperbolic or parabolic

2  
according as  $ac-b^2$  is positive, negative or zero. Useful definitions of the concepts of elliptic, hyperbolic and parabolic character can also be given for differential equations in more than two independent variables, for systems and for nonlinear differential equations.

For elliptic equations, of which Laplace's equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0 \quad (2)$$

is the simplest example of second order, the subsidiary conditions take the form of boundary conditions, i.e., conditions which provide information about the solution at all points of a closed boundary. For example, if equation (2) holds in a plane domain  $D$  bounded by a contour  $C$ , a solution  $u$  may be sought subject to the condition

$$u = f \quad \text{on } C, \quad (3)$$

where  $f$  is a given function. The condition (3) is known as a Dirichlet boundary condition. Equally common is the Neumann boundary condition

$$u' = g \quad \text{on } C, \quad (4)$$

which is one form of a more general condition

$$u' + fu = g \quad \text{on } C, \quad (5)$$

where  $u'$  denotes the derivative of  $u$  normal to the contour  $C$  and  $f$  and  $g$  are given functions. Provided that  $f$  and  $g$  satisfy certain restrictions, condition (5) yields a well-posed boundary value problem for Laplace's equation. In the case of the Neumann problem, one further piece of information, e.g. the value of  $u$  at a particular point, is necessary for uniqueness of the solution. Boundary conditions similar to the above are applicable to more general second order elliptic equations, whilst two such conditions are required for equations of fourth order.

For hyperbolic equations, the wave equation

$$\frac{\partial^2 u}{\partial t^2} - \frac{\partial^2 u}{\partial x^2} = 0 \quad (6)$$

is the simplest example of second order. It is equivalent to a first order system

$$\frac{\partial u}{\partial t} - v = 0, \quad \frac{\partial v}{\partial t} + u = 0. \quad (7)$$

The subsidiary conditions may take the form of initial conditions, i.e., conditions which provide information about the solution at points on a suitable open boundary. For example, if equation (6) is satisfied for  $t > 0$ , a solution  $u$  may be sought such that

$$u(x,0)=f(x), \quad u_t(x,0)=g(x), \quad (8)$$

where  $f$  and  $g$  are given functions. This is an example of an initial value problem, sometimes known as Cauchy's problem.

For parabolic equations, of which the heat conduction equation

$$u_t - u_{xx} = 0 \quad (9)$$

is the simplest example, the subsidiary conditions always include some of initial type and may also include some of boundary type. For example, if equation (9) is satisfied for  $t > 0$  and  $0 < x < 1$ , a solution  $u$  may be sought such that

$$u(x,0)=f(x), \quad 0 < x < 1, \quad (10)$$

and

$$u(0,t)=0, \quad u(1,t)=1, \quad t > 0. \quad (11)$$

This is an example of a mixed initial/boundary value problem.

For all types of partial differential equations, finite difference methods (Mitchell and Griffiths [5]) and finite element methods (Wait and Mitchell [9]) are the most common means of solution and such methods obviously feature prominently either in this chapter or in the companion NAG Finite Element Library. Many of the utility routines in this chapter are concerned with the solution of the large sparse systems of equations which arise from the finite difference and finite element methods.

Alternative methods of solution are often suitable for special classes of problems. For example, the method of characteristics is the most common for hyperbolic equations involving time and one space dimension (Smith [7]). The method of lines (see Mikhlin and Smolitsky [4]) may be used to reduce a parabolic equation to a (stiff) system of ordinary differential equations, which may be solved by means of routines from Chapter D02 -- Ordinary

Differential Equations. Similarly, integral equation or boundary element methods (Jaswon and Symm [3]) are frequently used for elliptic equations. Typically, in the latter case, the solution of a boundary value problem is represented in terms of certain boundary functions by an integral expression which satisfies the differential equation throughout the relevant domain. The boundary functions are obtained by applying the given boundary conditions to this representation. Implementation of this method necessitates discretisation of only the boundary of the domain, the dimensionality of the problem thus being effectively reduced by one. The boundary conditions yield a full system of simultaneous equations, as opposed to the sparse systems yielded by the finite difference and finite element methods, but the full system is usually of much lower order. Solution of this system yields the boundary functions, from which the solution of the problem may be obtained, by quadrature, as and where required.

### 3. Recommendations on Choice and Use of Routines

The choice of routine will depend first of all upon the type of partial differential equation to be solved. At present no special allowances are made for problems with boundary singularities such as may arise at corners of domains or at points where boundary conditions change. For such problems results should be treated with caution.

Users may wish to construct their own partial differential equation solution software for problems not solvable by the routines described in Sections 3.1 to 3.4 below. In such cases users can employ appropriate routines from the Linear Algebra Chapters to solve the resulting linear systems; see Section 3.5 for further details.

#### 3.1. Elliptic Equations

The routine D03EDF solves a system of seven-point difference equations in a rectangular grid (in two dimensions), using the multigrid iterative method. The equations are supplied by the user, and the seven-point form allows cross-derivative terms to be represented (see Mitchell and Griffiths [5]). The method is particularly efficient for large systems of equations with diagonal dominance.

The routine D03EEF discretises a second-order equation on a two-dimensional rectangular region using finite differences and a seven-point molecule. The routine allows for cross-derivative terms, Dirichlet, Neumann or mixed boundary conditions, and either central or upwind differences. The resulting seven-diagonal difference equations are in a form suitable for passing directly to the multigrid routine D03EDF, although other solution methods could easily be used.

The routine D03FAF, based on the routine HW3CRT from FISHPACK (Swarztrauber and Sweet [8]), solves the Helmholtz equation in a three-dimensional cuboidal region, with any combination of Dirichlet, Neumann or periodic boundary conditions. The method used is based on the fast Fourier transform algorithm, and is likely to be particularly efficient on vector-processing machines.

### 3.2. Hyperbolic Equations

There are no routines available yet for the solution of these equations.

### 3.3. Parabolic Equations

There are no routines available yet for the solution of these equations.

But problems in two space dimensions plus time may be treated as a succession of elliptic equations [1], [6] using appropriate D03E- routines or one may use codes from the NAG Finite Element Library.

### 3.4. Utility Routines

There are no utility routines available yet, but routines are available in the Linear Algebra Chapters for the direct and iterative solution of linear equations. Here we point to some of the routines that may be of use in solving the linear systems that arise from finite difference or finite element approximations to partial differential equation solutions. Chapters F01 and F04 should be consulted for further information and for the routine documents. Decision trees for the solution of linear systems are given in Section 3.5 of the F04 Chapter Introduction.

The following routines allow the direct solution of symmetric positive-definite systems:

|                            |                    |
|----------------------------|--------------------|
| Band                       | F04ACF             |
| Variable band<br>(skyline) | F01MCF and F04MCF  |
| Tridiagonal                | F04FAF             |
| Sparse                     | F01MAF* and F04MAF |

(\* the parameter DROPTL should be set to zero for F01MAF to give a direct solution)

and the following routines allow the iterative solution of symmetric positive-definite systems:

Sparse (incomplete F01MAF and F04MBF  
Cholesky)

Sparse (conjugate F04MBF  
gradient)

The latter routine above allows the user to supply a pre-conditioner and also allows the solution of indefinite symmetric systems.

The following routines allow the direct solution of unsymmetric systems:

|                       |                                |
|-----------------------|--------------------------------|
| Band                  | F01LBF and F04LDF              |
| Almost block-diagonal | F01LHF and F04LHF              |
| Tridiagonal           | F01LEF and F04LEF or F04EAF    |
| Sparse                | F01BRF (and F01BSF) and F04AXF |

and the following routine allows the iterative solution of unsymmetric systems:

|        |        |
|--------|--------|
| Sparse | F04QAF |
|--------|--------|

The above routine allows the user to supply a pre-conditioner and also allows the solution of least-squares systems.

 D03EDF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

D03EDF solves seven-diagonal systems of linear equations which arise from the discretization of an elliptic partial differential equation on a rectangular region. This routine uses a multigrid technique.

### 2. Specification

```

 SUBROUTINE D03EDF (NGX, NGY, LDA, A, RHS, UB, MAXIT, ACC,
1 US, U, IOUT, NUMIT, IFAIL)
 INTEGER NGX, NGY, LDA, MAXIT, IOUT, NUMIT, IFAIL
 DOUBLE PRECISION A(LDA,7), RHS(LDA), UB(NGX*NGY), ACC, US
1 (LDA), U(LDA)

```

### 3. Description

D03EDF solves, by multigrid iteration, the seven-point scheme

$$\begin{array}{ccccc}
 & 6 & & 7 & \\
 A & u & & +A & u \\
 & i,j & i-1,j+1 & i,j & i,j+1 \\
 \\
 & 3 & & 4 & & 5 \\
 +A & u & & +A & u & +A & u \\
 & i,j & i-1,j & i,j & i,j & i,j & i+1,j
 \end{array}$$

$$\begin{aligned}
& +A_{i,j}^1 u_{i,j-1} + A_{i,j}^2 u_{i+1,j-1} = f_{ij}, \\
& i=1,2,\dots,n; \quad j=1,2,\dots,n, \\
& \qquad \qquad \qquad x \qquad \qquad \qquad y
\end{aligned}$$

which arises from the discretization of an elliptic partial differential equation of the form

$$\begin{aligned}
& (\alpha)_{xx}(x,y)U + (\beta)_{xy}(x,y)U + (\gamma)_{yy}(x,y)U + (\delta)_{xx}(x,y)U \\
& + (\epsilon)_{xy}(x,y)U + (\phi)_{yy}(x,y)U = (\psi)_{xx}(x,y)
\end{aligned}$$

and its boundary conditions, defined on a rectangular region. This we write in matrix form as

$$Au=f$$

The algorithm is described in separate reports by Wesseling [2], [3] and McCarthy [1].

Systems of linear equations, matching the seven-point stencil defined above, are solved by a multigrid iteration. An initial estimate of the solution must be provided by the user. A zero guess may be supplied if no better approximation is available.

A 'smoother' based on incomplete Crout decomposition is used to eliminate the high frequency components of the error. A restriction operator is then used to map the system on to a sequence of coarser grids. The errors are then smoothed and prolonged (mapped onto successively finer grids). When the finest cycle is reached, the approximation to the solution is corrected. The cycle is repeated for MAXIT iterations or until the required accuracy, ACC, is reached.

D03EDF will automatically determine the number  $l$  of possible coarse grids, 'levels' of the multigrid scheme, for a particular problem. In other words, D03EDF determines the maximum integer  $l$  so that  $n_x$  and  $n_y$  can be expressed in the form

$$\begin{aligned}
& n_x = 2^{l-1} \cdot m_x \\
& n_y = 2^{l-1} \cdot m_y
\end{aligned}$$

$$n_x = m2 + 1, \quad n_y = n2 + 1, \quad \text{with } m \geq 2 \text{ and } n \geq 2.$$

It should be noted that the rate of convergence improves significantly with the number of levels used (see McCarthy [1]), so that  $n_x$  and  $n_y$  should be carefully chosen so that  $n_x - 1$  and  $n_y - 1$  have factors of the form  $2^l$ , with  $l$  as large as possible.

For good convergence the integer  $l$  should be at least 2.

D03EDF has been found to be robust in application, but being an iterative method the problem of divergence can arise. For a strictly diagonally dominant matrix  $A$

$$\begin{array}{ccc} & 4 & k \\ & ij & -- & ij \\ |A| & > & > & |A| \\ & -- & & \\ & k/4 & & \end{array}$$

no such problem is foreseen. The diagonal dominance of  $A$  is not a necessary condition, but should this condition be strongly violated then divergence may occur. The quickest test is to try the routine.

#### 5. Parameters

- 1: NGX -- INTEGER Input  
 On entry: the number of interior grid points in the  $x$ -direction,  $n_x$ .  $NGX - 1$  should preferably be divisible by as high a power of 2 as possible. Constraint:  $NGX \geq 3$ .

- 2: NGY -- INTEGER Input  
 On entry: the number of interior grid points in the y-direction,  $n_y$ . NGY-1 should preferably be divisible by as high a power of 2 as possible. Constraint: NGY  $\geq$  3.
- 3: LDA -- INTEGER Input  
 On entry: the first dimension of the array A as declared in the (sub)program from which D03EDF is called, which must also be a lower bound for the dimensions of the arrays RHS, US and U. It is always sufficient to set  $LDA \geq (4*(NGX+1)*(NGY+1))/3$ , but slightly smaller values may be permitted, depending on the values of NGX and NGY. If on entry, LDA is too small, an error message gives the minimum permitted value. (LDA must be large enough to allow space for the coarse-grid approximations).
- 4: A(LDA,7) -- DOUBLE PRECISION array Input/Output  
 $k$   
 On entry:  $A(i+(j-1)*NGX, k)$  must be set to  $A_{ij}^k$ , for  $i = 1, 2, \dots, NGX$ ;  $j = 1, 2, \dots, NGY$  and  $k = 1, 2, \dots, 7$ . On exit: A is overwritten.
- 5: RHS(LDA) -- DOUBLE PRECISION array Input/Output  
 On entry:  $RHS(i+(j-1)*NGX)$  must be set to  $f_{ij}$ , for  $i = 1, 2, \dots, NGX$ ;  $j = 1, 2, \dots, NGY$ . On exit: the first  $NGX*NGY$  elements are unchanged and the rest of the array is used as workspace.
- 6: UB(NGX\*NGY) -- DOUBLE PRECISION array Input/Output  
 On entry:  $UB(i+(j-1)*NGX)$  must be set to the initial estimate for the solution  $u_{ij}$ . On exit: the corresponding component of the residual  $r = f - Au$ .
- 7: MAXIT -- INTEGER Input  
 On entry: the maximum permitted number of multigrid iterations. If MAXIT = 0, no multigrid iterations are performed, but the coarse-grid approximations and incomplete Crout decompositions are computed, and may be output if IOUT is set accordingly. Constraint: MAXIT  $\geq$  0.
- 8: ACC -- DOUBLE PRECISION Input

On entry: the required tolerance for convergence of the residual 2-norm:

$$||r||_2 = \sqrt{\sum_{k=1}^{NGX*NGY} (r_k)^2}$$

where  $r=f-Au$  and  $u$  is the computed solution. Note that the norm is not scaled by the number of equations. The routine will stop after fewer than MAXIT iterations if the residual 2-norm is less than the specified tolerance. (If MAXIT > 0, at least one iteration is always performed.)

If on entry ACC = 0.0, then the machine precision is used as a default value for the tolerance; if ACC > 0.0, but ACC is less than the machine precision, then the routine will stop when the residual 2-norm is less than the machine precision and IFAIL will be set to 4. Constraint: ACC >= 0.0.

- 9: US(LDA) -- DOUBLE PRECISION array Output  
 On exit: the residual 2-norm, stored in element US(1).
- 10: U(LDA) -- DOUBLE PRECISION array Output  
 On exit: the computed solution  $u_{ij}$  is returned in  $U(i+(j-1)*NGX)$ , for  $i = 1,2,\dots,NGX$ ;  $j = 1,2,\dots,NGY$ .
- 11: IOUT -- INTEGER Input  
 On entry: controls the output of printed information to the advisory message unit as returned by X04ABF:  
 IOUT = 0  
     No output.  
 IOUT = 1  
     The solution  $u_{ij}$ , for  $i = 1,2,\dots,NGX$ ;  $j = 1,2,\dots,NGY$ .  
 IOUT = 2  
     The residual 2-norm after each iteration, with the reduction factor over the previous iteration.  
 IOUT = 3  
     As for IOUT = 1 and IOUT = 2.

IOUT = 4  
 As for IOUT = 3, plus the final residual (as returned in UB).

IOUT = 5  
 As for IOUT = 4, plus the initial elements of A and RHS.

IOUT = 6  
 As for IOUT = 5, plus the Galerkin coarse grid approximations.

IOUT = 7  
 As for IOUT = 6, plus the incomplete Crout decompositions.

IOUT = 8  
 As for IOUT = 7, plus the residual after each iteration.  
 The elements A(p,k), the Galerkin coarse grid approximations and the incomplete Crout decompositions are output in the format:

Y-index = j

X-index = i A(p,1) A(p,2) A(p,3) A(p,4) A(p,5) A(p,6)  
 A(p,7)

where  $p = i + (j-1) \times \text{NGX}$ ,  $i = 1, 2, \dots, \text{NGX}$  and  $j = 1, 2, \dots, \text{NGY}$ .

The vectors U(p), UB(p), RHS(p) are output in matrix form with NGY rows and NGX columns. Where  $\text{NGX} > 10$ , the NGX values for a given j-value are produced in rows of 10. Values of IOUT > 4 may yield considerable amounts of output. Constraint:  $0 \leq \text{IOUT} \leq 8$ .

12: NUMIT -- INTEGER Output  
 On exit: the number of iterations performed.

13: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry `IFAIL = 0` or `-1`, explanatory error messages are output on the current error message unit (as defined by `X04AAF`).

`IFAIL= 1`

On entry `NGX < 3`,

or `NGY < 3`,

or `LDA` is too small,

or `ACC < 0.0`,

or `MAXIT < 0`,

or `IOUT < 0`,

or `IOUT > 8`.

`IFAIL= 2`

`MAXIT` iterations have been performed with the residual 2-norm decreasing at each iteration but the residual 2-norm has not been reduced to less than the specified tolerance (see `ACC`). Examine the progress of the iteration by setting `IOUT >= 2`.

`IFAIL= 3`

As for `IFAIL = 2`, except that at one or more iterations the residual 2-norm did not decrease. It is likely that the method fails to converge for the given matrix `A`.

`IFAIL= 4`

On entry `ACC` is less than the machine precision. The routine terminated because the residual norm is less than the machine precision.

## 7. Accuracy

See `ACC` (Section 5).

## 8. Further Comments

The rate of convergence of this routine is strongly dependent upon the number of levels,  $l$ , in the multigrid scheme, and thus the choice of  $NGX$  and  $NGY$  is very important. The user is advised to experiment with different values of  $NGX$  and  $NGY$  to see the effect they have on the rate of convergence; for example, using a

value such as  $NGX = 65 (=2^6 + 1)$  followed by  $NGX = 64$  (for which  $l = 1$ ).

#### 9. Example

The program solves the elliptic partial differential equation

$$U_{xx} - (\alpha)U_{xy} + U_{yy} = -4, \quad (\alpha) = 1.7$$

on the unit square  $0 \leq x, y \leq 1$ , with boundary conditions

$$\begin{aligned} & \{x=0, (0 \leq y \leq 1) \\ & U=0 \text{ on } \{y=0, (0 \leq x \leq 1) \} \cup \{y=1, (0 \leq x \leq 1) \} \\ & U=1 \text{ on } x=1, \quad 0 \leq y \leq 1. \end{aligned}$$

For the equation to be elliptic,  $(\alpha)$  must be less than 2.

The equation is discretized on a square grid with mesh spacing  $h$  in both directions using the following approximations:

Please see figure in printed Reference Manual

$$U_{xx} \sim \frac{1}{h^2} (U_E - 2U_O + U_W)$$

$$U_{yy} \sim \frac{1}{h^2} (U_N - 2U_O + U_S)$$

$$U_{xy} \sim \frac{1}{2h^2} (U_{NW} - U_{NE} - U_{SW} + U_{SE})$$

Thus the following equations are solved:

$$\begin{aligned}
 & \frac{1}{2} \frac{\partial}{\partial x} \left( -(\alpha) u \right)_{i-1,j+1} + \frac{1}{2} \frac{\partial}{\partial x} \left( (1 - (\alpha)) u \right)_{i,j+1} \\
 & + \frac{1}{2} \frac{\partial}{\partial x} \left( (1 - (\alpha)) u \right)_{i-1,j} + \frac{1}{2} \frac{\partial}{\partial x} \left( (-4 + (\alpha)) u \right)_{ij} + \frac{1}{2} \frac{\partial}{\partial x} \left( (1 - (\alpha)) u \right)_{i+1,j} \\
 & + \frac{1}{2} \frac{\partial}{\partial x} \left( (1 - (\alpha)) u \right)_{i,j-1} + \frac{1}{2} \frac{\partial}{\partial x} \left( -(\alpha) u \right)_{i+1,j-1} \\
 & = -4h
 \end{aligned}$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

D03 -- Partial Differential Equations D03EEF  
D03EEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

D03EEF discretizes a second order elliptic partial differential equation (PDE) on a rectangular region.

### 2. Specification

```

SUBROUTINE D03EEF (XMIN, XMAX, YMIN, YMAX, PDEF, BNDY,
1 NGX, NGY, LDA, A, RHS, SCHEME, IFAIL)
 INTEGER NGX, NGY, LDA, IFAIL
 DOUBLE PRECISION XMIN, XMAX, YMIN, YMAX, A(LDA,7), RHS(LDA)
 CHARACTER*1 SCHEME
 EXTERNAL PDEF, BNDY

```

## 3. Description

D03EEF discretizes a second order linear elliptic partial differential equation of the form

$$\begin{aligned}
 & (\alpha)(x,y) \frac{\partial^2 U}{\partial x^2} + (\beta)(x,y) \frac{\partial^2 U}{\partial x \partial y} + (\gamma)(x,y) \frac{\partial^2 U}{\partial y^2} \\
 & + (\delta)(x,y) \frac{\partial U}{\partial x} + (\epsilon)(x,y) \frac{\partial U}{\partial y} + (\phi)(x,y)U = (\psi)(x,y) \quad (1)
 \end{aligned}$$

on a rectangular region

$$x_A \leq x \leq x_B$$

$$y_A \leq y \leq y_B$$

subject to boundary conditions of the form

$$a(x,y)U + b(x,y) \frac{\partial U}{\partial n} = c(x,y)$$

where  $\frac{\partial U}{\partial n}$  denotes the outward pointing normal derivative on the boundary. Equation (1) is said to be elliptic if

$$4(\alpha)(x,y)(\gamma)(x,y) > ((\beta)(x,y))^2$$

for all points in the rectangular region. The linear equations produced are in a form suitable for passing directly to the multigrid routine D03EDF.

The equation is discretized on a rectangular grid, with  $n_x$  grid

points in the x-direction and  $n_y$  grid points in the y-direction.

The grid spacing used is therefore

$$h_x = (x_B - x_A) / (n_x - 1)$$

$$h_y = (y_B - y_A) / (n_y - 1)$$

and the co-ordinates of the grid points  $(x_{ij}, y_{ij})$  are

$$x_{ij} = x_A + (i-1)h_x, \quad i=1,2,\dots,n_x,$$

$$y_{ij} = y_A + (j-1)h_y, \quad j=1,2,\dots,n_y.$$

At each grid point  $(x_{ij}, y_{ij})$  six neighbouring grid points are used

to approximate the partial differential equation, so that the equation is discretized on the following seven-point stencil:

Please see figure in printed Reference Manual

For convenience the approximation  $u_{ij}$  to the exact solution

$U(x_{ij}, y_{ij})$  is denoted by  $u_{ij}$ , and the neighbouring approximations are labelled according to points of the compass as shown. Where numerical labels for the seven points are required, these are also shown above.

The following approximations are used for the second derivatives:

$$\frac{d^2 U}{dx^2} \approx \frac{1}{h_x^2} (u_E - 2u_0 + u_W)$$

$$\begin{aligned} \frac{\partial^2 U}{\partial y^2} &= \frac{1}{h^2} (u_{N-2} - 2u_{N-1} + u_N) \\ \frac{\partial^2 U}{\partial x^2} &= \frac{1}{h^2} (u_{W-2} - 2u_{W-1} + u_W + u_{E-2} - 2u_{E-1} + u_E + u_{SE-2} - 2u_{SE-1} + u_{SE}) \end{aligned}$$

Two possible schemes may be used to approximate the first derivatives:

#### Central Differences

$$\begin{aligned} \frac{\partial U}{\partial x} &= \frac{1}{2h} (u_W - u_E) \\ \frac{\partial U}{\partial y} &= \frac{1}{2h} (u_N - u_S) \end{aligned}$$

#### Upwind Differences

$$\begin{aligned} \frac{\partial U}{\partial x} &= \frac{1}{h} (u_E - u_N) \text{ if } (\text{delta})(x,y) > 0 \\ \frac{\partial U}{\partial x} &= \frac{1}{h} (u_W - u_N) \text{ if } (\text{delta})(x,y) < 0 \\ \frac{\partial U}{\partial y} &= \frac{1}{h} (u_N - u_O) \text{ if } (\text{epsilon})(x,y) > 0 \\ \frac{\partial U}{\partial y} &= \frac{1}{h} (u_W - u_O) \text{ if } (\text{epsilon})(x,y) < 0 \end{aligned}$$

$$\frac{ddU}{dy} = \frac{h}{2} \left( \frac{U_0 - U_S}{h} \right)$$

Central differences are more accurate than upwind differences, but upwind differences may lead to a more diagonally dominant matrix for those problems where the coefficients of the first derivatives are significantly larger than the coefficients of the second derivatives.

The approximations used for the first derivatives may be written in a more compact form as follows:

$$\frac{ddU}{dx} = \frac{1}{2h} \left( (k_x - 1)U_W - 2k_x U_0 + (k_x + 1)U_E \right)$$

$$\frac{ddU}{dy} = \frac{1}{2h} \left( (k_y - 1)U_S - 2k_y U_0 + (k_y + 1)U_N \right)$$

where  $k_x = \text{sign}(\Delta x)$  and  $k_y = \text{sign}(\Delta y)$  for upwind differences, and  $k_x = k_y = 0$  for central differences.

At all points in the rectangular domain, including the boundary, the coefficients in the partial differential equation are evaluated by calling the user-supplied subroutine PDEF, and applying the approximations. This leads to a seven-diagonal system of linear equations of the form:

$$\begin{aligned} & A_{ij}^{(6)} u_{i-1,j+1} + A_{ij}^{(7)} u_{i,j+1} \\ & + A_{ij}^{(3)} u_{i-1,j} + A_{ij}^{(4)} u_{ij} + A_{ij}^{(5)} u_{i+1,j} \\ & + A_{ij}^{(1)} u_{i,j-1} + A_{ij}^{(2)} u_{i+1,j-1} = f_{ij}, \quad i=1,2,\dots,n; j=1,2,\dots,n, \end{aligned}$$

where the coefficients are given by

$$A_{ij}^{(1)} = 1, \quad A_{ij}^{(2)} = 1, \quad A_{ij}^{(3)} = 1, \quad A_{ij}^{(4)} = 1$$

$$A_{ij} = (\beta_{ij}) \frac{(x,y)^{2h}}{x^2 y^2} + (\gamma_{ij}) \frac{(x,y)^2}{h^2} + (\epsilon_{ij}) \frac{(x,y)^{2h}}{y^2} (k-1)$$

$$A_{ij} = -(\beta_{ij}) \frac{(x,y)^{2h}}{x^2 y^2}$$

$$A_{ij} = (\alpha_{ij}) \frac{(x,y)^2}{h^2} + (\beta_{ij}) \frac{(x,y)^{2h}}{x^2 y^2} + (\delta_{ij}) \frac{(x,y)^{2h}}{x^2} (k-1)$$

$$A_{ij} = -(\alpha_{ij}) \frac{(x,y)^2}{h^2} - (\beta_{ij}) \frac{(x,y)^{2h}}{x^2 y^2} - (\gamma_{ij}) \frac{(x,y)^2}{h^2} (k-1)$$

$$-(\delta_{ij}) \frac{(x,y)^k}{h^2} - (\epsilon_{ij}) \frac{(x,y)^k}{h^2} - (\phi_{ij}) \frac{(x,y)^k}{h^2}$$

$$A_{ij} = (\alpha_{ij}) \frac{(x,y)^2}{h^2} + (\beta_{ij}) \frac{(x,y)^{2h}}{x^2 y^2} + (\delta_{ij}) \frac{(x,y)^{2h}}{x^2} (k+1)$$

$$A_{ij} = -(\beta_{ij}) \frac{(x,y)^{2h}}{x^2 y^2}$$

$$A_{ij} = (\beta_{ij}) \frac{(x,y)^{2h}}{x^2 y^2} + (\gamma_{ij}) \frac{(x,y)^2}{h^2} + (\epsilon_{ij}) \frac{(x,y)^{2h}}{y^2} (k+1)$$

$$f_{ij} = (\psi_{ij})(x,y)$$

These equations then have to be modified to take account of the boundary conditions. These may be Dirichlet (where the solution is given), Neumann (where the derivative of the solution is given), or mixed (where a linear combination of solution and derivative is given).

If the boundary conditions are Dirichlet, there are an infinity of possible equations which may be applied:

$$(\mu)u_{ij} = (\mu)f_{ij}, \quad (\mu) \neq 0. \quad (2)$$

If D03EDF is used to solve the discretized equations, it turns out that the choice of  $(\mu)$  can have a dramatic effect on the rate of convergence, and the obvious choice  $(\mu)=1$  is not the best. Some choices may even cause the multigrid method to fail altogether. In practice it has been found that a value of the same order as the other diagonal elements of the matrix is best, and the following value has been found to work well in practice:

$$(\mu) = \min_{ij} \left( \frac{2}{h_x^2 + h_y^2} \right), A_{ij}.$$

If the boundary conditions are either mixed or Neumann (i.e.,  $B \neq 0$  on return from the user-supplied subroutine BNDY), then one of the points in the seven-point stencil lies outside the domain. In this case the normal derivative in the boundary conditions is used to eliminate the 'fictitious' point,  $u_{\text{outside}}$ :

$$\frac{ddU}{ddn} = \frac{1}{2h} (u_{\text{outside}} - u_{\text{inside}}). \quad (3)$$

It should be noted that if the boundary conditions are Neumann and  $(\phi)(x,y)=0$ , then there is no unique solution. The routine returns with IFAIL = 5 in this case, and the seven-diagonal matrix is singular.

The four corners are treated separately. The user-supplied subroutine BNDY is called twice, once along each of the edges meeting at the corner. If both boundary conditions at this point

are Dirichlet and the prescribed solution values agree, then this value is used in an equation of the form (2). If the prescribed solution is discontinuous at the corner, then the average of the two values is used. If one boundary condition is Dirichlet and the other is mixed, then the value prescribed by the Dirichlet condition is used in an equation of the form given above. Finally, if both conditions are mixed or Neumann, then two 'fictitious' points are eliminated using two equations of the form (3).

It is possible that equations for which the solution is known at all points on the boundary, have coefficients which are not defined on the boundary. Since this routine calls the user-supplied subroutine PDEF at all points in the domain, including boundary points, arithmetic errors may occur in the user's routine PDEF which this routine cannot trap. If the user has an equation with Dirichlet boundary conditions (i.e.,  $B = 0$  at all points on the boundary), but with PDE coefficients which are singular on the boundary, then D03EDF could be called directly only using interior grid points with the user's own discretization.

After the equations have been set up as described above, they are checked for diagonal dominance. That is to say,

$$|A_{ij}| > \sum_{k \neq j} |A_{ik}|, \quad i=1,2,\dots,n; \quad j=1,2,\dots,n.$$

If this condition is not satisfied then the routine returns with IFAIL = 6. The multigrid routine D03EDF may still converge in this case, but if the coefficients of the first derivatives in the partial differential equation are large compared with the coefficients of the second derivative, the user should consider using upwind differences (SCHEME = 'U').

Since this routine is designed primarily for use with D03EDF, this document should be read in conjunction with the document for that routine.

## 5. Parameters

- 1: XMIN -- DOUBLE PRECISION Input
- 2: XMAX -- DOUBLE PRECISION Input  
 On entry: the lower and upper x co-ordinates of the  
 rectangular region respectively,  $x_A$  and  $x_B$ . Constraint: XMIN  
 $< x_B$ .  
 $< x_A$ .
- 3: YMIN -- DOUBLE PRECISION Input
- 4: YMAX -- DOUBLE PRECISION Input  
 On entry: the lower and upper y co-ordinates of the  
 rectangular region respectively,  $y_A$  and  $y_B$ . Constraint: YMIN  
 $< y_B$ .  
 $< y_A$ .
- 5: PDEF -- SUBROUTINE, supplied by the user. External Procedure  
 PDEF must evaluate the functions (alpha)(x,y), (beta)(x,y),  
 (gamma)(x,y), (delta)(x,y), (epsilon)(x,y), (phi)(x,y) and  
 (psi)(x,y) which define the equation at a general point  
 (x,y).

Its specification is:

```

 SUBROUTINE PDEF (X, Y, ALPHA, BETA, GAMMA,
1 DELTA, EPSLON, PHI, PSI)
 DOUBLE PRECISION X, Y, ALPHA, BETA, GAMMA, DELTA,
1 EPSLON, PHI, PSI

```

- 1: X -- DOUBLE PRECISION Input
- 2: Y -- DOUBLE PRECISION Input  
 On entry: the x and y co-ordinates of the point at  
 which the coefficients of the partial differential  
 equation are to be evaluated. 8
- 3: ALPHA -- DOUBLE PRECISION Output
- 4: BETA -- DOUBLE PRECISION Output
- 5: GAMMA -- DOUBLE PRECISION Output

15.21. PACKAGE NAGD03 NAGPARTIALDIFFERENTIAL EQUATIONSPACKAGE2407

6: DELTA -- DOUBLE PRECISION Output  
 7: EPSLON -- DOUBLE PRECISION Output  
 8: PHI -- DOUBLE PRECISION Output

9: PSI -- DOUBLE PRECISION Output  
 On exit: ALPHA, BETA, GAMMA, DELTA, EPSLON, PHI and PSI must be set to the values of (alpha)(x,y), (beta)(x,y), (gamma)(x,y), (delta)(x,y), (epsilon)(x,y), (phi)(x,y) and (psi)(x,y) respectively at the point specified by X and Y.

PDEF must be declared as EXTERNAL in the (sub)program from which D03EEF is called. Parameters denoted as Input must not be changed by this procedure.

6: BNDY -- SUBROUTINE, supplied by the user. External Procedure  
 BNDY must evaluate the functions a(x,y), b(x,y), and c(x,y) involved in the boundary conditions.

Its specification is:

```
SUBROUTINE BNDY (X, Y, A, B, C, IBND)
 INTEGER IBND
 DOUBLE PRECISION X, Y, A, B, C
```

1: X -- DOUBLE PRECISION Input  
 2: Y -- DOUBLE PRECISION Input  
 On entry: the x and y co-ordinates of the point at which the boundary conditions are to be evaluated.  
 3: A -- DOUBLE PRECISION Output  
 4: B -- DOUBLE PRECISION Output  
 5: C -- DOUBLE PRECISION Output  
 On exit: A, B and C must be set to the values of the functions appearing in the boundary conditions.  
 6: IBND -- INTEGER Input  
 On entry: specifies on which boundary the point (X,Y) lies. IBND = 0, 1, 2 or 3 according as the point lies on the bottom, right, top or left boundary.

BNDY must be declared as EXTERNAL in the (sub)program

from which D03EEF is called. Parameters denoted as Input must not be changed by this procedure.

- 7: NGX -- INTEGER Input
- 8: NGY -- INTEGER Input  
 On entry: the number of interior grid points in the x- and y-  
 directions respectively, n<sub>x</sub> and n<sub>y</sub>. If the seven-diagonal  
 equations are to be solved by D03EDF, then NGX-1 and NGY-1  
 should preferably be divisible by as high a power of 2 as  
 possible. Constraint: NGX ≥ 3, NGY ≥ 3.
- 9: LDA -- INTEGER Input  
 On entry:  
 the first dimension of the array A as declared in the  
 (sub)program from which D03EEF is called.  
 Constraint: if only the seven-diagonal equations are  
 required, then LDA ≥ NGX\*NGY. If a call to this routine is  
 to be followed by a call to D03EDF to solve the seven-  
 diagonal linear equations, LDA ≥ (4\*(NGX+1)\*(NGY+1))/3.
- Note: this routine only checks the former condition. D03EDF,  
 if called, will check the latter condition.
- 10: A(LDA,7) -- DOUBLE PRECISION array Output  
 On exit: A(i,j), for i=1,2,...,NGX\*NGY; j = 1,2,...,7,  
 contains the seven-diagonal linear equations produced by the  
 discretization described above. If LDA > NGX\*NGY, the  
 remaining elements are not referenced by the routine, but if  
 LDA ≥ (4\*(NGX+1)\*(NGY+1))/3 then the array A can be passed  
 directly to D03EDF, where these elements are used as  
 workspace.
- 11: RHS(LDA) -- DOUBLE PRECISION array Output  
 On exit: the first NGX\*NGY elements contain the right-hand  
 sides of the seven-diagonal linear equations produced by the  
 discretization described above. If LDA > NGX\*NGY, the  
 remaining elements are not referenced by the routine, but if  
 LDA ≥ (4\*(NGX+1)\*(NGY+1))/3 then the array RHS can be  
 passed directly to D03EDF, where these elements are used as  
 workspace.
- 12: SCHEME -- CHARACTER\*1 Input  
 On entry: the type of approximation to be used for the first  
 derivatives which occur in the partial differential

equation.

If SCHEME = 'C', then central differences are used.

If SCHEME = 'U', then upwind differences are used.

Constraint: SCHEME = 'C' or 'U'.

Note: generally speaking, if at least one of the coefficients multiplying the first derivatives (DELTA or EPSILON as returned by PDEF) are large compared with the coefficients multiplying the second derivatives, then upwind differences may be more appropriate. Upwind differences are less accurate than central differences, but may result in more rapid convergence for strongly convective equations. The easiest test is to try both schemes.

13: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.

On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).

For this routine, because the values of output parameters may be useful even if IFAIL  $\neq$  0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

## 6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry XMIN  $\geq$  XMAX,

or YMIN  $\geq$  YMAX,

or NGX  $<$  3,

or NGY  $<$  3,

or LDA  $<$  NGX\*NGY,

or SCHEME is not one of 'C' or 'U'.

IFAIL= 2

At some point on the boundary there is a derivative in the boundary conditions ( $B \neq 0$  on return from a BNDY) and there

is a non-zero coefficient of the mixed derivative  $\frac{\partial^2 U}{\partial x \partial y}$  (BETA  $\neq 0$  on return from PDEF).

IFAIL= 3

A null boundary has been specified, i.e., at some point both A and B are zero on return from a call to BNDY.

IFAIL= 4

The equation is not elliptic, i.e.,  $4 \cdot \text{ALPHA} \cdot \text{GAMMA} < \text{BETA}^2$  after a call to PDEF. The discretization has been completed, but the convergence of D03EDF cannot be guaranteed.

IFAIL= 5

The boundary conditions are purely Neumann (only the derivative is specified) and there is, in general, no unique solution.

IFAIL= 6

The equations were not diagonally dominant. (See Section 3).

#### 7. Accuracy

Not applicable.

#### 8. Further Comments

If this routine is used as a pre-processor to the multigrid routine D03EDF it should be noted that the rate of convergence of that routine is strongly dependent upon the number of levels in the multigrid scheme, and thus the choice of NGX and NGY is very important.

#### 9. Example

The program solves the elliptic partial differential equation

$$\frac{\partial^2 U}{\partial x^2} + \frac{\partial^2 U}{\partial y^2} + 50 \left\{ \frac{\partial^2 U}{\partial x^2} + \frac{\partial^2 U}{\partial y^2} \right\} = f(x,y)$$

on the unit square  $0 \leq x, y \leq 1$ , with boundary conditions

$\frac{\partial U}{\partial n}$  given on  $x=0$  and  $y=0$ ,  
 $\frac{\partial U}{\partial n}$

$U$  given on  $x=1$  and  $y=1$ .

The function  $f(x,y)$  and the exact form of the boundary conditions are derived from the exact solution  $U(x,y) = \sin x \sin y$ .

The equation is first solved using central differences. Since the coefficients of the first derivatives are large, the linear equations are not diagonally dominated, and convergence is slow. The equation is solved a second time with upwind differences, showing that convergence is more rapid, but the solution is less accurate.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

D03 -- Partial Differential Equations D03FAF  
D03FAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

D03FAF solves the Helmholtz equation in Cartesian co-ordinates in three dimensions using the standard seven-point finite difference approximation. This routine is designed to be particularly efficient on vector processors.

### 2. Specification

```

SUBROUTINE D03FAF (XS, XF, L, LBDCND, BDXS, BDXF, YS, YF,
1 M, MBDCND, BDYS, BDYF, ZS, ZF, N,
2 NBDCND, BDZS, BDZF, LAMBDA, LDIMF,
3 MDIMF, F, PERTRB, W, LWRK, IFAIL)
INTEGER L, LBDCND, M, MBDCND, N, NBDCND, LDIMF,
1 MDIMF, LWRK, IFAIL
DOUBLE PRECISION XS, XF, BDXS(MDIMF,N+1), BDXF(MDIMF,N+1),
1 YS, YF, BDYS(LDIMF,N+1), BDYF(LDIMF,N+1),
2 ZS, ZF, BDZS(LDIMF,M+1), BDZF(LDIMF,M+1),
3 LAMBDA, F(LDIMF,MDIMF,N+1), PERTRB, W
4 (LWRK)

```

### 3. Description

D03FAF solves the three-dimensional Helmholtz equation in cartesian co-ordinates:

$$\begin{array}{c}
 \begin{array}{ccc}
 \frac{\partial^2}{\partial x^2} & \frac{\partial^2}{\partial y^2} & \frac{\partial^2}{\partial z^2}
 \end{array} \\
 \text{dd u} & \text{dd u} & \text{dd u} \\
 \text{----+} & \text{----+} & \text{----+} \\
 \frac{\partial^2}{\partial x^2} & \frac{\partial^2}{\partial y^2} & \frac{\partial^2}{\partial z^2}
 \end{array}
 + (\text{lambda})u = f(x,y,z)$$

This subroutine forms the system of linear equations resulting from the standard seven-point finite difference equations, and then solves the system using a method based on the fast Fourier transform (FFT) described by Swarztrauber [1]. This subroutine is based on the routine HW3CRT from FISHPACK (see Swarztrauber and Sweet [2]).

More precisely, the routine replaces all the second derivatives by second-order central difference approximations, resulting in a block tridiagonal system of linear equations. The equations are modified to allow for the prescribed boundary conditions. Either the solution or the derivative of the solution may be specified on any of the boundaries, or the solution may be specified to be periodic in any of the three dimensions. By taking the discrete Fourier transform in the x- and y-directions, the equations are reduced to sets of tridiagonal systems of equations. The Fourier transforms required are computed using the multiple FFT routines found in Chapter C06 of the NAG Fortran Library.

## 5. Parameters

- 1: XS -- DOUBLE PRECISION Input  
On entry: the lower bound of the range of x, i.e.,  $XS \leq x \leq XF$ . Constraint:  $XS < XF$ .
- 2: XF -- DOUBLE PRECISION Input  
On entry: the upper bound of the range of x, i.e.,  $XS \leq x \leq XF$ . Constraint:  $XS < XF$ .
- 3: L -- INTEGER Input  
On entry: the number of panels into which the interval (XS,XF) is subdivided. Hence, there will be L+1 grid points in the x-direction given by  $x = XS + (i-1) \cdot (\Delta x)$ , for  $i = 1, 2, \dots, L+1$ , where  $(\Delta x) = (XF - XS)/L$  is the panel width. Constraint:  $L \geq 5$ .
- 4: LBDCND -- INTEGER Input  
On entry: indicates the type of boundary conditions at  $x = XS$  and  $x = XF$ .  
LBDCND = 0  
if the solution is periodic in x, i.e.,  
 $u(XS, y, z) = u(XF, y, z)$ .  
  
LBDCND = 1  
if the solution is specified at  $x = XS$  and  $x = XF$ .  
  
LBDCND = 2  
if the solution is specified at  $x = XS$  and the derivative of the solution with respect to x is specified at  $x = XF$ .  
  
LBDCND = 3  
if the derivative of the solution with respect to x is specified at  $x = XS$  and  $x = XF$ .  
  
LBDCND = 4  
if the derivative of the solution with respect to x is

specified at  $x = XS$  and the solution is specified at  $x = XF$ .

Constraint:  $0 \leq LBDCND \leq 4$ .

- 5:  $BDXS(MDIMF, N+1)$  -- DOUBLE PRECISION array Input  
 On entry: the values of the derivative of the solution with respect to  $x$  at  $x = XS$ . When  $LBDCND = 3$  or  $4$ ,  $BDXS(j, k) = u_x(XS, y_j, z_k)$ , for  $j=1, 2, \dots, M+1$ ;  $k=1, 2, \dots, N+1$ .

When  $LBDCND$  has any other value,  $BDXS$  is not referenced.

- 6:  $BDXF(MDIMF, N+1)$  -- DOUBLE PRECISION array Input  
 On entry: the values of the derivative of the solution with respect to  $x$  at  $x = XF$ . When  $LBDCND = 2$  or  $3$ ,  $BDXF(j, k) = u_x(XF, y_j, z_k)$ , for  $j=1, 2, \dots, M+1$ ;  $k=1, 2, \dots, N+1$ .

When  $LBDCND$  has any other value,  $BDXF$  is not referenced.

- 7:  $YS$  -- DOUBLE PRECISION Input  
 On entry: the lower bound of the range of  $y$ , i.e.,  $YS \leq y \leq YF$ . Constraint:  $YS < YF$ .

- 8:  $YF$  -- DOUBLE PRECISION Input  
 On entry: the upper bound of the range of  $y$ , i.e.,  $YS \leq y \leq YF$ . Constraint:  $YS < YF$ .

- 9:  $M$  -- INTEGER Input  
 On entry: the number of panels into which the interval  $(YS, YF)$  is subdivided. Hence, there will be  $M+1$  grid points in the  $y$ -direction given by  $y_j = YS + (j-1)(\Delta y)$  for  $j=1, 2, \dots, M+1$ , where  $(\Delta y) = (YF - YS)/M$  is the panel width. Constraint:  $M \geq 5$ .

- 10:  $MBDCND$  -- INTEGER Input  
 On entry: indicates the type of boundary conditions at  $y = YS$  and  $y = YF$ .  
 $MBDCND = 0$   
     if the solution is periodic in  $y$ , i.e.,  
      $u(x, YF, z) = u(x, YS, z)$ .

$MBDCND = 1$   
     if the solution is specified at  $y = YS$  and  $y = YF$ .

MBDCND = 2

if the solution is specified at  $y = YS$  and the derivative of the solution with respect to  $y$  is specified at  $y = YF$ .

MBDCND = 3

if the derivative of the solution with respect to  $y$  is specified at  $y = YS$  and  $y = YF$ .

MBDCND = 4

if the derivative of the solution with respect to  $y$  is specified at  $y = YS$  and the solution is specified at  $y = YF$ .

Constraint:  $0 \leq MBDCND \leq 4$ .

- 11: BDYS(LDIMF,N+1) -- DOUBLE PRECISION array Input  
 On entry: the values of the derivative of the solution with respect to  $y$  at  $y = YS$ . When  $MBDCND = 3$  or  $4$ ,  $BDYS(i,k) = u(x_i, y, z_k)$ , for  $i=1,2,\dots,L+1$ ;  $k=1,2,\dots,N+1$ .  
 $y \quad i \quad s \quad k$

When  $MBDCND$  has any other value,  $BDYS$  is not referenced.

- 12: BDYF(LDIMF,N+1) -- DOUBLE PRECISION array Input  
 On entry: the values of the derivative of the solution with respect to  $y$  at  $y = YF$ . When  $MBDCND = 2$  or  $3$ ,  $BDYF(i,k) = u(x_i, YF, z_k)$ , for  $i=1,2,\dots,L+1$ ;  $k=1,2,\dots,N+1$ .  
 $y \quad i \quad k$

When  $MBDCND$  has any other value,  $BDYF$  is not referenced.

- 13: ZS -- DOUBLE PRECISION Input  
 On entry: the lower bound of the range of  $z$ , i.e.,  $ZS \leq z \leq ZF$ . Constraint:  $ZS < ZF$ .

- 14: ZF -- DOUBLE PRECISION Input  
 On entry: the upper bound of the range of  $z$ , i.e.,  $ZS \leq z \leq ZF$ . Constraint:  $ZS < ZF$ .

- 15: N -- INTEGER Input  
 On entry: the number of panels into which the interval  $(ZS, ZF)$  is subdivided. Hence, there will be  $N+1$  grid points in the  $z$ -direction given by  $z = ZS + (k-1) \cdot (\Delta z)$ , for  $k=1,2,\dots,N+1$ , where  $(\Delta z) = (ZF - ZS)/N$  is the panel width.  
 Constraint:  $N \geq 5$ .

- 16: NDBCND -- INTEGER Input  
 On entry: specifies the type of boundary conditions at  $z =$   
 $ZS$  and  $z = ZF$ .  
 NDBCND = 0  
     if the solution is periodic in  $z$ , i.e.,  
      $u(x,y,ZF)=u(x,y,ZS)$ .  
  
 NDBCND = 1  
     if the solution is specified at  $z = ZS$  and  $z = ZF$ .  
  
 NDBCND = 2  
     if the solution is specified at  $z = ZS$  and the  
     derivative of the solution with respect to  $z$  is  
     specified at  $z = ZF$ .  
  
 NDBCND = 3  
     if the derivative of the solution with respect to  $z$  is  
     specified at  $z = ZS$  and  $z = ZF$ .  
  
 NDBCND = 4  
     if the derivative of the solution with respect to  $z$  is  
     specified at  $z = ZS$  and the solution is specified at  $z$   
     =  $ZF$ .  
 Constraint:  $0 \leq \text{NDBCND} \leq 4$ .
- 17: BDZS(LDIMF,M+1) -- DOUBLE PRECISION array Input  
 On entry: the values of the derivative of the solution with  
 respect to  $z$  at  $z = ZS$ . When NDBCND = 3 or 4, BDZS  
 $(i,j)=u(x,y,ZS)=u(x,y,z)$ , for  $i=1,2,\dots,L+1$ ;  
      $z$      $i$      $j$   
 $j=1,2,\dots,M+1$ .  
  
 When NDBCND has any other value, BDZS is not referenced.
- 18: BDZF(LDIMF,M+1) -- DOUBLE PRECISION array Input  
 On entry: the values of the derivative of the solution with  
 respect to  $z$  at  $z = ZF$ . When NDBCND = 2 or 3, BDZF  
 $(i,j)=u(x,y,ZF)=u(x,y,z)$ , for  $i=1,2,\dots,L+1$ ;  
      $z$      $i$      $j$   
 $j=1,2,\dots,M+1$ .  
  
 When NDBCND has any other value, BDZF is not referenced.
- 19: LAMBDA -- DOUBLE PRECISION Input  
 On entry: the constant ( $\lambda$ ) in the Helmholtz equation.

For certain positive values of (lambda) a solution to the differential equation may not exist, and close to these values the solution of the discretized problem will be extremely ill-conditioned. If (lambda)>0, then D03FAF will set IFAIL to 3, but will still attempt to find a solution. However, since in general the values of (lambda) for which no solution exists cannot be predicted a priori, the user is advised to treat any results computed with (lambda)>0 with great caution.

20: LDIMF -- INTEGER Input  
 On entry:  
 the first dimension of the arrays F, BDYS, BDYF, BDZS and BDZF as declared in the (sub)program from which D03FAF is called.  
 Constraint: LDIMF >= L + 1.

21: MDIMF -- INTEGER Input  
 On entry: the second dimension of the array F and the first dimension of the arrays BDXS and BDXF as declared in the (sub)program from which D03FAF is called.  
 Constraint: MDIMF >= M + 1.

22: F(LDIMF,MDIMF,N+1) -- DOUBLE PRECISION array Input/Output  
 On entry: the values of the right-side of the Helmholtz equation and boundary values (if any).

$F(i,j,k) = f(x_i, y_j, z_k)$   $i=2,3,\dots,L$ ,  $j=2,3,\dots,M$  and  $k=2,3,\dots,N$ .

On the boundaries F is defined by  
 LBDCND  $F(1,j,k)$   $F(L+1,j,k)$

0  $f(x_S, y_j, z_k)$   $f(x_S, y_j, z_k)$

1  $u(x_S, y_j, z_k)$   $u(x_F, y_j, z_k)$

2  $u(x_S, y_j, z_k)$   $f(x_F, y_j, z_k)$   $j=1,2,\dots,M+1$

3  $f(x_S, y_j, z_k)$   $f(x_F, y_j, z_k)$   $k=1,2,\dots,N+1$

4             $f(XS, y_j, z_k) u(XF, y_j, z_k)$

MBDCND     $F(i, 1, k) \quad F(i, M+1, k)$

0             $f(x_i, yS, z_k) f(x_i, yS, z_k)$

1             $u(x_i, yS, z_k) u(x_i, yF, z_k)$

2             $u(x_i, yS, z_k) f(x_i, yF, z_k) \quad i=1, 2, \dots, L+1$

3             $f(x_i, yS, z_k) f(x_i, yF, z_k) \quad k=1, 2, \dots, N+1$

4             $f(x_i, yS, z_k) u(x_i, yF, z_k)$

NBDCND     $F(i, j, 1) \quad F(i, j, N+1)$

0             $f(x_i, y_j, ZS) f(x_i, y_j, ZS)$

1             $u(x_i, y_j, ZS) u(x_i, y_j, ZF)$

2             $u(x_i, y_j, ZS) f(x_i, y_j, ZF) \quad i=1, 2, \dots, L+1$

3             $f(x_i, y_j, ZS) f(x_i, y_j, ZF) \quad j=1, 2, \dots, M+1$

4             $f(x_i, y_j, ZS) u(x_i, y_j, ZF)$

Note: if the table calls for both the solution  $u$  and the right-hand side  $f$  on a boundary, then the solution must be specified. On exit:  $F$  contains the solution  $u(i, j, k)$  of the finite difference approximation for the grid point (

$x_i, y_j, z_k$  for  $i=1,2,\dots,L+1$ ,  $j=1,2,\dots,M+1$  and  $k=1,2,\dots,N+1$ .

- 23: PERTRB -- DOUBLE PRECISION Output  
 On exit: PERTRB = 0, unless a solution to Poisson's equation ( $\lambda=0$ ) is required with a combination of periodic or derivative boundary conditions (LBDCND, MBDCND and NBDCND = 0 or 3). In this case a solution may not exist. PERTRB is a constant, calculated and subtracted from the array F, which ensures that a solution exists. D03FAF then computes this solution, which is a least-squares solution to the original approximation. This solution is not unique and is unnormalised. The value of PERTRB should be small compared to the right-hand side F, otherwise a solution has been obtained to an essentially different problem. This comparison should always be made to insure that a meaningful solution has been obtained.
- 24: W(LWRK) -- DOUBLE PRECISION array Workspace
- 25: LWRK -- INTEGER Input  
 On entry:  
 the dimension of the array W as declared in the (sub)program from which D03FAF is called.  
 $LWRK \geq 2*(N+1)*\max(L,M)+3*L+3*M+4*N+6$  is an upper bound on the required size of W. If LWRK is too small, the routine exits with IFAIL = 2, and if on entry IFAIL = 0 or IFAIL = -1, a message is output giving the exact value of LWRK required to solve the current problem.
- 26: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to the Essential Introduction for details.  
  
 On exit: IFAIL = 0 unless the routine detects an error or gives a warning (see Section 6).  
  
 For this routine, because the values of output parameters may be useful even if IFAIL  $\neq$  0 on exit, users are recommended to set IFAIL to -1 before entry. It is then essential to test the value of IFAIL on exit.

## 6. Error Indicators and Warnings

Errors or warnings specified by the routine:

If on entry  $IFAIL = 0$  or  $-1$ , explanatory error messages are output on the current error message unit (as defined by  $X04AAF$ ).

$IFAIL = 1$

On entry  $XS \geq XF$ ,

or  $L < 5$ ,

or  $LBDCND < 0$ ,

or  $LBDCND > 4$ ,

or  $YS \geq YF$ ,

or  $M < 5$ ,

or  $MBDCND < 0$ ,

or  $MBDCND > 4$ ,

or  $ZS \geq ZF$ ,

or  $N < 5$ ,

or  $NBDCND < 0$ ,

or  $NBDCND > 4$ ,

or  $LDIMF < L + 1 > 0$ ,

or  $MDIMF < M + 1$ .

$IFAIL = 2$

On entry  $LWRK$  is too small.

$IFAIL = 3$

On entry  $(\lambda) > 0$ .

## 7. Accuracy

None.

## 8. Further Comments

The execution time is roughly proportional to

$L*M*N*(\log L + \log M + 5)$ , but also depends on input parameters  
 $\frac{2}{2}$   
 LBDCND and MBDCND.

### 9. Example

The example solves the Helmholtz equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} + (\lambda)u = f(x,y,z)$$

for  $(x,y,z)$  is in  $[0,1] \times [0,2(\pi)] \times [0, \frac{\pi}{2}]$  where  $(\lambda) = -2$ , and  
 $f(x,y,z)$  is derived from the exact solution

$$u(x,y,z) = x^4 \sin(y) \cos(z).$$

The equation is subject to the following boundary conditions,  
 again derived from the exact solution given above.

$u(0,y,z)$  and  $u(1,y,z)$  are prescribed (i.e., LBDCND = 1).

$u(x,0,z) = u(x,2(\pi),z)$  (i.e., MBDCND = 0).

$u(x,y,0)$  and  $u(x,y, \frac{\pi}{2})$  are prescribed (i.e. NBDCND = 2).

The example program is not reproduced here. The source code for  
 all example programs is distributed with the NAG Foundation  
 Library software and should be available on-line.

C02(3NAG)

C02 -- Zeros of Polynomials

Introduction -- C02

Chapter C02

Zeros of Polynomials

### 1. Scope of the Chapter

This chapter is concerned with computing the zeros of a polynomial with real or complex coefficients.

### 2. Background to the Problems

Let  $f(z)$  be a polynomial of degree  $n$  with complex coefficients  $a_i$ :

$$f(z) = a_n z^n + a_{n-1} z^{n-1} + a_{n-2} z^{n-2} + \dots + a_{n-1} z + a_n, \quad a_n \neq 0.$$

A complex number  $z_1$  is called a zero of  $f(z)$  (or equivalently a root of the equation  $f(z)=0$ ), if:

$$f(z_1) = 0.$$

If  $z_1$  is a zero, then  $f(z)$  can be divided by a factor  $(z - z_1)$ :

$$f(z) = (z - z_1) f_1(z) \quad (1)$$

where  $f_1(z)$  is a polynomial of degree  $n-1$ . By the Fundamental

Theorem of Algebra, a polynomial  $f(z)$  always has a zero, and so the process of dividing out factors  $(z - z_i)$  can be continued until

we have a complete factorization of  $f(z)$

$$f(z) = a_0 (z - z_1)(z - z_2) \dots (z - z_n).$$

Here the complex numbers  $z_1, z_2, \dots, z_n$  are the zeros of  $f(z)$ ; they may not all be distinct, so it is sometimes more convenient to write:

$$f(z) = a_0 (z - z_1)^{m_1} (z - z_2)^{m_2} \dots (z - z_k)^{m_k}, \quad k \leq n,$$

with distinct zeros  $z_1, z_2, \dots, z_k$  and multiplicities  $m_i \geq 1$ . If  $m_i = 1$ ,  $z_i$  is called a single zero, if  $m_i > 1$ ,  $z_i$  is called a multiple or repeated zero; a multiple zero is also a zero of the derivative of  $f(z)$ .

If the coefficients of  $f(z)$  are all real, then the zeros of  $f(z)$  are either real or else occur as pairs of conjugate complex numbers  $x+iy$  and  $x-iy$ . A pair of complex conjugate zeros are the zeros of a quadratic factor of  $f(z)$ ,  $(z^2 + rz + s)$ , with real coefficients  $r$  and  $s$ .

Mathematicians are accustomed to thinking of polynomials as pleasantly simple functions to work with. However the problem of numerically computing the zeros of an arbitrary polynomial is far from simple. A great variety of algorithms have been proposed, of which a number have been widely used in practice; for a fairly comprehensive survey, see Householder [1]. All general algorithms are iterative. Most converge to one zero at a time; the corresponding factor can then be divided out as in equation (1) above - this process is called deflation or, loosely, dividing out the zero - and the algorithm can be applied again to the polynomial  $f_1(z)$ . A pair of complex conjugate zeros can be divided out together - this corresponds to dividing  $f(z)$  by a quadratic factor.

Whatever the theoretical basis of the algorithm, a number of practical problems arise: for a thorough discussion of some of them see Peters and Wilkinson [2] and Wilkinson [3]. The most

elementary point is that, even if  $z$  is mathematically an exact zero of  $f(z)$ , because of the fundamental limitations of computer arithmetic the computed value of  $f(z)$  will not necessarily be exactly 0.0. In practice there is usually a small region of values of  $z$  about the exact zero at which the computed value of  $f(z)$  becomes swamped by rounding errors. Moreover in many algorithms this inaccuracy in the computed value of  $f(z)$  results in a similar inaccuracy in the computed step from one iterate to the next. This limits the precision with which any zero can be computed. Deflation is another potential cause of trouble, since, in the notation of equation (1), the computed coefficients of  $f(z)$  will not be completely accurate, especially if  $z$  is not an exact zero of  $f(z)$ ; so the zeros of the computed  $f(z)$  will deviate from the zeros of  $f(z)$ .

A zero is called ill-conditioned if it is sensitive to small changes in the coefficients of the polynomial. An ill-conditioned zero is likewise sensitive to the computational inaccuracies just mentioned. Conversely a zero is called well-conditioned if it is comparatively insensitive to such perturbations. Roughly speaking a zero which is well separated from other zeros is well-conditioned, while zeros which are close together are ill-conditioned, but in talking about 'closeness' the decisive factor is not the absolute distance between neighbouring zeros but their ratio: if the ratio is close to 1 the zeros are ill-conditioned. In particular, multiple zeros are ill-conditioned. A multiple zero is usually split into a cluster of zeros by perturbations in the polynomial or computational inaccuracies.

### 3. Recommendations on Choice and Use of Routines

## 3.1. Discussion

Two routines are available: C02AFF for polynomials with complex coefficients and C02AGF for polynomials with real coefficients.

C02AFF and C02AGF both use a variant of Laguerre's Method due to BT Smith to calculate each zero until the degree of the deflated polynomial is less than 3, whereupon the remaining zeros are obtained using the 'standard' closed formulae for a quadratic or linear equation.

The accuracy of the roots will depend on how ill-conditioned they are. Peters and Wilkinson [2] describe techniques for estimating the errors in the zeros after they have been computed.

| C02AFF -- NAG Foundation Library Routine Document |        |

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

C02AFF finds all the roots of a complex polynomial equation,

using a variant of Laguerre's Method.

## 2. Specification

```

SUBROUTINE C02AFF (A, N, SCALE, Z, W, IFAIL)
 INTEGER N, IFAIL
 DOUBLE PRECISION A(2,N+1), Z(2,N), W(4*(N+1))
 LOGICAL SCALE

```

## 3. Description

The routine attempts to find all the roots of the  $n$ th degree complex polynomial equation

$$P(z) = a_0 z^n + a_1 z^{n-1} + a_2 z^{n-2} + \dots + a_{n-1} z + a_n = 0.$$

The roots are located using a modified form of Laguerre's Method, originally proposed by Smith [2].

The method of Laguerre [3] can be described by the iterative scheme

$$L_k(z) = z_k - z_k \frac{-n P(z_k)}{P'(z_k) \pm \sqrt{H(z_k)}},$$

where  $H(z_k) = (n-1) * [(n-1) * (P'(z_k))^2 - n P(z_k) P''(z_k)]$ , and  $z_0$  is specified.

The sign in the denominator is chosen so that the modulus of the Laguerre step at  $z_k$ , viz.  $|L(z_k)|$ , is as small as possible. The method can be shown to be cubically convergent for isolated roots (real or complex) and linearly convergent for multiple roots. The routine generates a sequence of iterates  $z_1, z_2, z_3, \dots$ , such that  $|P(z_{k+1})| < |P(z_k)|$  and ensures that  $z_{k+1} + L(z_{k+1})$  'roughly' lies inside a circular region of radius  $|F|$  about  $z_k$  known to

contain a zero of  $P(z)$ ; that is,  $|L(z_{k+1})| \leq |F|$ , where  $F$  denotes the Fejer bound (see Marden [1]) at the point  $z_k$ . Following Smith [2],  $F$  is taken to be  $\min(B, 1.445 \cdot n \cdot R)$ , where  $B$  is an upper bound for the magnitude of the smallest zero given by

$$B = 1.0001 \cdot \min\left(\frac{1}{n} |L(z_k)|, |r_1|, |a_1/a_0|\right),$$

$r_1$  is the zero  $X$  of smaller magnitude of the quadratic equation

$$2(P'(z_k)/(2 \cdot n \cdot (n-1)))X^2 + 2(P'(z_k)/n)X + P(z_k) = 0$$

and the Cauchy lower bound  $R$  for the smallest zero is computed (using Newton's Method) as the positive root of the polynomial equation

$$|a_0|z^n + |a_1|z^{n-1} + |a_2|z^{n-2} + \dots + |a_{n-1}|z - |a_n| = 0.$$

Starting from the origin, successive iterates are generated according to the rule  $z_{k+1} = z_k + L(z_k)$  for  $k = 1, 2, 3, \dots$  and  $L(z_k)$  is 'adjusted' so that  $|P(z_{k+1})| < |P(z_k)|$  and  $|L(z_{k+1})| \leq |F|$ . The iterative procedure terminates if  $P(z_{k+1})$  is smaller in absolute value than the bound on the rounding error in  $P(z_{k+1})$  and the current iterate  $z_{k+1}$  is taken to be a zero of  $P(z)$ . The

deflated polynomial  $P(z) = P(z)/(z - z_{k+1})$  of degree  $n-1$  is then

formed, and the above procedure is repeated on the deflated polynomial until  $n < 3$ , whereupon the remaining roots are obtained via the 'standard' closed formulae for a linear ( $n = 1$ ) or quadratic ( $n = 2$ ) equation.

To obtain the roots of a quadratic polynomial, CO2AHF(\*) can be used.

- [3] Wilkinson J H (1965) The Algebraic Eigenvalue Problem. Clarendon Press.

#### 5. Parameters

- 1: A(2,N+1) -- DOUBLE PRECISION array Input  
 On entry: if A is declared with bounds (2,0:N), then A(1,i) and A(2,i) must contain the real and imaginary parts of a  

i

$n-i$

 (i.e., the coefficient of  $z^{n-i}$ ), for  $i=0,1,\dots,n$ .  
 Constraint: A(1,0)  $\neq$  0.0 or A(2,0)  $\neq$  0.0.
- 2: N -- INTEGER Input  
 On entry: the degree of the polynomial, n. Constraint: N  $\geq$  1.
- 3: SCALE -- LOGICAL Input  
 On entry: indicates whether or not the polynomial is to be scaled. See Section 8 for advice on when it may be preferable to set SCALE = .FALSE. and for a description of the scaling strategy. Suggested value: SCALE = .TRUE..
- 4: Z(2,N) -- DOUBLE PRECISION array Output  
 On exit: the real and imaginary parts of the roots are stored in Z(1,i) and Z(2,i) respectively, for  $i=1,2,\dots,n$ .
- 5: W(4\*(N+1)) -- DOUBLE PRECISION array Workspace
- 6: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry  $A(1,0) = 0.0$  and  $A(2,0) = 0.0$ ,

or  $N < 1$ .

IFAIL= 2

The iterative procedure has failed to converge. This error is very unlikely to occur. If it does, please contact NAG immediately, as some basic assumption for the arithmetic has been violated. See also Section 8.

IFAIL= 3

Either overflow or underflow prevents the evaluation of  $P(z)$  near some of its zeros. This error is very unlikely to occur. If it does, please contact NAG immediately. See also Section 8.

## 7. Accuracy

All roots are evaluated as accurately as possible, but because of the inherent nature of the problem complete accuracy cannot be guaranteed.

## 8. Further Comments

If SCALE = .TRUE., then a scaling factor for the coefficients is chosen as a power of the base B of the machine so that the largest coefficient in magnitude approaches  $\text{THRESH} = B^{\text{EMAX}-P}$ . Users should note that no scaling is performed if the largest coefficient in magnitude exceeds THRESH, even if SCALE = .TRUE.. (For definition of B, EMAX and P see the Chapter Introduction X02.)

However, with SCALE = .TRUE., overflow may be encountered when

the input coefficients  $a_0, a_1, a_2, \dots, a_n$  vary widely in magnitude,

(4\*P)

particularly on those machines for which  $B$  overflows. In such cases, SCALE should be set to .FALSE. and the coefficients scaled so that the largest coefficient in magnitude does not exceed  $B$ .

Even so, the scaling strategy used in CO2AFF is sometimes insufficient to avoid overflow and/or underflow conditions. In such cases, the user is recommended to scale the independent variable ( $z$ ) so that the disparity between the largest and smallest coefficient in magnitude is reduced. That is, use the routine to locate the zeros of the polynomial  $dP(cz)$  for some suitable values of  $c$  and  $d$ . For example, if the original

polynomial was  $P(z) = 2 \times 10^{100} z^2 + 100 z - 10$ , then choosing  $c = 2 \times 10^{100}$  and  $d = 2 \times 10^{-10}$ , for instance, would yield the scaled polynomial  $1 + z$ , which is well-behaved relative to overflow and underflow and has zeros which are  $2 \times 10^{10}$  times those of  $P(z)$ .

If the routine fails with IFAIL = 2 or 3, then the real and imaginary parts of any roots obtained before the failure occurred are stored in Z in the reverse order in which they were found. Let  $n_R$  denote the number of roots found before the failure

occurred. Then  $Z(1, n_R)$  and  $Z(2, n_R)$  contain the real and imaginary parts of the 1st root found,  $Z(1, n_R - 1)$  and  $Z(2, n_R - 1)$  contain the real and imaginary parts of the 2nd root found, ...,  $Z(1, 1)$  and  $Z(2, 1)$  contain the real and imaginary parts of the  $n_R$ th root found. After the failure has occurred, the remaining  $2 \times (n - n_R)$  elements of Z contain a large negative number (equal to

$-1/(X02AMF().\sqrt{2})$ ).

#### 9. Example

To find the roots of the polynomial  $a_5 z^5 + a_4 z^4 + a_3 z^3 + a_2 z^2 + a_1 z + a_0 = 0$ ,

```

 0 1 2 3 4 5
where a =(5.0+6.0i), a =(30.0+20.0i), a =(0.2+6.0i),
 0 1 2
a =(50.0+100000.0i), a =(2.0-40.0i) and a =(10.0+1.0i).
 3 4 5

```

### 1. Purpose

CO2AGF finds all the roots of a real polynomial equation, using a variant of Laguerre's Method.

### 2. Specification

```

SUBROUTINE CO2AGF (A, N, SCALE, Z, W, IFAIL)
INTEGER N, IFAIL
DOUBLE PRECISION A(N+1), Z(2,N), W(2*(N+1))
LOGICAL SCALE

```

### 3. Description

The routine attempts to find all the roots of the nth degree real polynomial equation

$$P(z) = a_0 z^n + a_1 z^{n-1} + a_2 z^{n-2} + \dots + a_{n-1} z + a_n = 0.$$

The roots are located using a modified form of Laguerre's Method, originally proposed by Smith [2].

The method of Laguerre [3] can be described by the iterative scheme

$$L(z)_k = z_k - z_k \frac{-n P(z)_k}{P'(z)_k + \frac{-n P(z)_k}{H(z)_k}},$$

where  $H(z)_k = (n-1) * [(n-1) * (P'(z)_k)^2 - n P(z)_k P''(z)_k]$ , and  $z_0$  is specified.

The sign in the denominator is chosen so that the modulus of the Laguerre step at  $z_k$ , viz.  $|L(z)_k|$ , is as small as possible. The method can be shown to be cubically convergent for isolated roots (real or complex) and linearly convergent for multiple roots. The routine generates a sequence of iterates  $z_1, z_2, z_3, \dots$ , such that  $|P(z_{k+1})| < |P(z_k)|$  and ensures that  $z_{k+1} + L(z)_k$  'roughly' lies inside a circular region of radius  $|F|$  about  $z_k$  known to contain a zero of  $P(z)$ ; that is,  $|L(z)_{k+1}| \leq |F|$ , where  $F$  denotes the Fejer bound (see Marden [1]) at the point  $z_k$ . Following Smith [2],  $F$  is taken to be  $\min(B, 1.445 * n * R)$ , where  $B$  is an upper bound for the magnitude of the smallest zero given by

$$B = 1.0001 * \min\left(\frac{1}{n} L(z)_k, |r_1|, |a_1/a_0|\right),$$

$r_1$  is the zero of smaller magnitude of the quadratic equation

$$2(P''(z)_k / (2 * n * (n-1))) X^2 + 2(P'(z)_k / n) X + P(z)_k = 0$$

and the Cauchy lower bound  $R$  for the smallest zero is computed (using Newton's Method) as the positive root of the polynomial

equation

$$|a_0|z^n + |a_1|z^{n-1} + |a_2|z^{n-2} + \dots + |a_{n-1}|z - |a_n| = 0.$$

Starting from the origin, successive iterates are generated according to the rule  $z_{k+1} = z_k + L(z_k)$  for  $k=1,2,3,\dots$  and  $L(z_k)$  is

iterative procedure terminates if  $P(z_{k+1})$  is smaller in absolute value than the bound on the rounding error in  $P(z_{k+1})$  and the current iterate  $z_{k+1}$  is taken to be a zero of  $P(z)$  (as is its conjugate  $\bar{z}_{k+1}$  if  $z_{k+1}$  is complex). The deflated polynomial  $\tilde{P}(z) = P(z)/(z - z_{k+1})$  of degree  $n-1$  if  $z_{k+1}$  is real or  $\tilde{P}(z) = P(z)/((z - z_{k+1})(z - \bar{z}_{k+1}))$  of degree  $n-2$  if  $z_{k+1}$  is complex is then formed, and the above procedure is repeated on the deflated polynomial until  $n < 3$ , whereupon the remaining roots are obtained via the 'standard' closed formulae for a linear ( $n = 1$ ) or quadratic ( $n = 2$ ) equation.

To obtain the roots of a quadratic polynomial, C02AJF(\*) can be used.

## 5. Parameters

- 1: A(N+1) -- DOUBLE PRECISION array Input  
 On entry: if A is declared with bounds (0:N), then A(i)  

$$\text{must contain a } \underset{i}{\text{ }} \text{ (i.e., the coefficient of } z^{\underset{i}{n-i}} \text{), for}$$

$$i=0,1,\dots,n. \text{ Constraint: } A(0) \neq 0.0.$$
- 2: N -- INTEGER Input  
 On entry: the degree of the polynomial, n. Constraint: N ≥ 1.
- 3: SCALE -- LOGICAL Input  
 On entry: indicates whether or not the polynomial is to be scaled. See Section 8 for advice on when it may be preferable to set SCALE = .FALSE. and for a description of the scaling strategy. Suggested value: SCALE = .TRUE..
- 4: Z(2,N) -- DOUBLE PRECISION array Output  
 On exit: the real and imaginary parts of the roots are stored in Z(1,i) and Z(2,i) respectively, for i=1,2,...,n. Complex conjugate pairs of roots are stored in consecutive pairs of elements of Z; that is, Z(1,i+1) = Z(1,i) and Z(2,i+1) = -Z(2,i).
- 5: W(2\*(N+1)) -- DOUBLE PRECISION array Workspace
- 6: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry A(0) = 0.0,

or  $N < 1$ .

IFAIL= 2

The iterative procedure has failed to converge. This error is very unlikely to occur. If it does, please contact NAG immediately, as some basic assumption for the arithmetic has been violated. See also Section 8.

IFAIL= 3

Either overflow or underflow prevents the evaluation of  $P(z)$  near some of its zeros. This error is very unlikely to occur. If it does, please contact NAG immediately. See also Section 8.

## 7. Accuracy

All roots are evaluated as accurately as possible, but because of the inherent nature of the problem complete accuracy cannot be guaranteed.

## 8. Further Comments

If SCALE = .TRUE., then a scaling factor for the coefficients is chosen as a power of the base B of the machine so that the largest coefficient in magnitude approaches  $\text{THRESH} = B^{\text{EMAX}-P}$ . Users should note that no scaling is performed if the largest coefficient in magnitude exceeds THRESH, even if SCALE = .TRUE.. (For definition of B, EMAX and P see the Chapter Introduction X02.)

However, with SCALE = .TRUE., overflow may be encountered when the input coefficients  $a_0, a_1, a_2, \dots, a_n$  vary widely in magnitude,

$(4 \times P)$

particularly on those machines for which B overflows. In such cases, SCALE should be set to .FALSE. and the coefficients scaled so that the largest coefficient in magnitude does not exceed  $B^{\text{EMAX}-2 \times P}$ .

Even so, the scaling strategy used in C02AGF is sometimes insufficient to avoid overflow and/or underflow conditions. In such cases, the user is recommended to scale the independent variable (z) so that the disparity between the largest and smallest coefficient in magnitude is reduced. That is, use the

routine to locate the zeros of the polynomial  $dP(cz)$  for some suitable values of  $c$  and  $d$ . For example, if the original polynomial was  $P(z) = 2 \frac{-100}{100} + 2 \frac{100}{100} z + 20 \frac{-10}{20}$ , then choosing  $c = 2$  and  $d = 2$ , for instance, would yield the scaled polynomial  $1+z$ , which is well-behaved relative to overflow and underflow and has zeros which are  $2^{10}$  times those of  $P(z)$ .

If the routine fails with  $IFAIL = 2$  or  $3$ , then the real and imaginary parts of any roots obtained before the failure occurred are stored in  $Z$  in the reverse order in which they were found. Let  $n$  denote the number of roots found before the failure

occurred. Then  $Z(1,n)$  and  $Z(2,n)$  contain the real and imaginary parts of the 1st root found,  $Z(1,n-1)$  and  $Z(2,n-1)$  contain the real and imaginary parts of the 2nd root found, ...,  $Z(1,n)$  and  $Z(2,n)$  contain the real and imaginary parts of the  $n$ th root found. After the failure has occurred, the remaining  $2*(n-n)$  elements of  $Z$  contain a large negative number (equal to

$-1/(X02AMF().\sqrt{2}))$ .

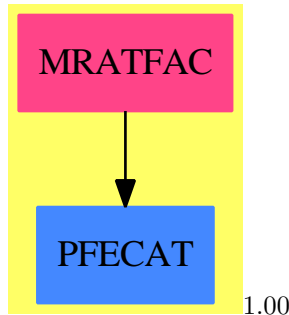

#### 9. Example

To find the roots of the 5th degree polynomial

$$z^5 + 2z^4 + 3z^3 + 4z^2 + 5z + 6 = 0.$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

C05(3NAG)

C05 -- Roots of One or More Transcendental Equations

Introduction -- C05

Chapter C05

Roots of One or More Transcendental Equations

### 1. Scope of the Chapter

This chapter is concerned with the calculation of real zeros of continuous real functions of one or more variables. (Complex equations must be expressed in terms of the equivalent larger system of real equations.)

### 2. Background to the Problems

The chapter divides naturally into two parts.

#### 2.1. A Single Equation

The first deals with the real zeros of a real function of a single variable  $f(x)$ .

At present, there is only one routine with a simple calling sequence. This routine assumes that the user can determine an initial interval  $[a,b]$  within which the desired zero lies, that is  $f(a)*f(b)<0$ , and outside which all other zeros lie. The routine then systematically subdivides the interval to produce a final interval containing the zero. This final interval has a length bounded by the user's specified error requirements; the end of the interval where the function has smallest magnitude is returned as the zero. This routine is guaranteed to converge to a simple zero of the function. (Here we define a simple zero as a zero corresponding to a sign-change of the function.) The algorithm used is due to Bus and Dekker.

#### 2.2. Systems of Equations

The routines in the second part of this chapter are designed to solve a set of nonlinear equations in  $n$  unknowns

$$f_i(x) = 0, \quad i = 1, 2, \dots, n, \quad x = (x_1, x_2, \dots, x_n)^T \quad (1)$$

where T stands for transpose.

It is assumed that the functions are continuous and differentiable so that the matrix of first partial derivatives of the functions, the Jacobian matrix  $J_{ij}(x) = \text{ddf} / \text{ddx}$  evaluated at the point  $x$ , exists, though it may not be possible to calculate it directly.

The functions  $f_i$  must be independent, otherwise there will be an infinity of solutions and the methods will fail. However, even when the functions are independent the solutions may not be unique. Since the methods are iterative, an initial guess at the solution has to be supplied, and the solution located will usually be the one closest to this initial guess.

## 3. Recommendations on Choice and Use of Routines

### 3.1. Zeros of Functions of One Variable

There is only one routine (C05ADF) for solving a single nonlinear equation. This routine is designed for solving problems where the function  $f(x)$  whose zero is to be calculated, can be coded as a user-supplied routine.

C05ADF may only be used when the user can supply an interval  $[a,b]$  containing the zero, that is  $f(a)*f(b)<0$ .

### 3.2. Solution of Sets of Nonlinear Equations

The solution of a set of nonlinear equations

$$f(x_1, x_2, \dots, x_n) = 0, \quad i=1, 2, \dots, n \quad (2)$$

can be regarded as a special case of the problem of finding a minimum of a sum of squares

$$s(x) = \sum_{i=1}^m [f(x_1, x_2, \dots, x_n)]^2 \quad (m \geq n). \quad (3)$$

So the routines in Chapter E04 of the Library are relevant as well as the special nonlinear equations routines.

There are two routines (C05NBF and C05PBF) for solving a set of nonlinear equations. These routines require the  $f_i$  (and possibly their derivatives) to be calculated in user-supplied routines. These should be set up carefully so the Library routines can work as efficiently as possible.

The main decision which has to be made by the user is whether to

supply the derivatives  $\frac{df_i}{dx_j}$ . It is advisable to do so if

possible, since the results obtained by algorithms which use derivatives are generally more reliable than those obtained by algorithms which do not use derivatives.

C05PBF requires the user to provide the derivatives, whilst C05NBF does not. C05NBF and C05PBF are easy-to-use routines. A routine, C05ZAF, is provided for use in conjunction with C05PBF to check the user-provided derivatives for consistency with the functions themselves. The user is strongly advised to make use of this routine whenever C05PBF is used.

Firstly, the calculation of the functions and their derivatives should be ordered so that cancellation errors are avoided. This is particularly important in a routine that uses these quantities to build up estimates of higher derivatives.

Secondly, scaling of the variables has a considerable effect on the efficiency of a routine. The problem should be designed so that the elements of  $x$  are of similar magnitude. The same comment applies to the functions, all the  $f_i$  should be of comparable size.

The accuracy is usually determined by the accuracy parameters of the routines, but the following points may be useful:

- (i) Greater accuracy in the solution may be requested by choosing smaller input values for the accuracy parameters. However, if unreasonable accuracy is demanded, rounding errors may become important and cause a failure.
- (ii) Some idea of the accuracies of the  $x_i$  may be obtained by monitoring the progress of the routine to see how many figures remain unchanged during the last few iterations.
- (iii) An approximation to the error in the solution  $x$ , given by  $e$  where  $e$  is the solution to the set of linear equations

$$J(x)e = -f(x)$$

$$\text{where } f(x) = (f_1(x), f_2(x), \dots, f_n(x))^T \quad (\text{see Chapter F04}).$$

- (iv) If the functions  $f_i(x)$  are changed by small amounts  $(\epsilon_i)$ , for  $i=1,2,\dots,n$ , then the corresponding change in the solution  $x$  is given approximately by  $(\sigma)$ , where  $(\sigma)$  is the solution of the set of linear equations

$$J(x)(\sigma) = -(\epsilon), \quad (\text{see Chapter F04}).$$

Thus one can estimate the sensitivity of  $x$  to any uncertainties in the specification of  $f(x)$ , for

i

i=1,2,...,n.

Foundation Library (12/10/92)

C05ADF(3NAG)

C05 -- Roots of One or More Transcendental Equations

C05ADF

C05ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for  
your implementation to check implementation-dependent details.  
The symbol (\*) after a NAG routine name denotes a routine that is  
not included in the Foundation Library.

## 1. Purpose

C05ADF locates a zero of a continuous function in a given

interval by a combination of the methods of linear interpolation, extrapolation and bisection.

## 2. Specification

```
SUBROUTINE C05ADF (A, B, EPS, ETA, F, X, IFAIL)
 INTEGER IFAIL
 DOUBLE PRECISION A, B, EPS, ETA, F, X
 EXTERNAL F
```

## 3. Description

The routine attempts to obtain an approximation to a simple zero of the function  $f(x)$  given an initial interval  $[a,b]$  such that  $f(a)*f(b) \leq 0$ . The zero is found by calls to C05AZF(\*) whose specification should be consulted for details of the method used.

The approximation  $x$  to the zero ( $\alpha$ ) is determined so that one or both of the following criteria are satisfied:

(i)  $|x - (\alpha)| < \text{EPS}$ ,

(ii)  $|f(x)| < \text{ETA}$ .

## 4. References

None.

## 5. Parameters

- 1: A -- DOUBLE PRECISION Input  
On entry: the lower bound of the interval, a.
- 2: B -- DOUBLE PRECISION Input  
On entry: the upper bound of the interval, b. Constraint: B  $\neq$  A.
- 3: EPS -- DOUBLE PRECISION Input  
On entry: the absolute tolerance to which the zero is required (see Section 3). Constraint: EPS > 0.0.
- 4: ETA -- DOUBLE PRECISION Input  
On entry: a value such that if  $|f(x)| < \text{ETA}$ , x is accepted as the zero. ETA may be specified as 0.0 (see Section 7).
- 5: F -- DOUBLE PRECISION FUNCTION, supplied by the user.

## External Procedure

F must evaluate the function  $f$  whose zero is to be determined.

Its specification is:

```
DOUBLE PRECISION FUNCTION F (XX)
DOUBLE PRECISION XX
```

1: XX -- DOUBLE PRECISION

Input

On entry: the point at which the function must be evaluated.

F must be declared as EXTERNAL in the (sub)program from which C05ADF is called. Parameters denoted as Input must not be changed by this procedure.

6: X -- DOUBLE PRECISION

Output

On exit: the approximation to the zero.

7: IFAIL -- INTEGER

Input/Output

Before entry, IFAIL must be assigned a value. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

Unless the routine detects an error (see Section 6), IFAIL contains 0 on exit.

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

On entry  $\text{EPS} \leq 0.0$ ,

or  $A = B$ ,

or  $F(A) \cdot F(B) > 0.0$ .

IFAIL= 2

Too much accuracy has been requested in the computation, that is, EPS is too small for the computer being used. The final value of X is an accurate approximation to the zero.

IFAIL= 3

A change in sign of  $f(x)$  has been determined as occurring near the point defined by the final value of X. However,

there is some evidence that this sign-change corresponds to a pole of  $f(x)$ .

IFAIL= 4

Indicates that a serious error has occurred in C05AZF(\*).  
Check all routine calls. Seek expert help.

#### 7. Accuracy

This depends on the value of EPS and ETA. If full machine accuracy is required, they may be set very small, resulting in an error exit with IFAIL = 2, although this may involve more iterations than a lesser accuracy. The user is recommended to set ETA = 0.0 and to use EPS to control the accuracy, unless he has considerable knowledge of the size of  $f(x)$  for values of  $x$  near the zero.

#### 8. Further Comments

The time taken by the routine depends primarily on the time spent evaluating  $F$  (see Section 5).

If it is important to determine an interval of length less than EPS containing the zero, or if the function  $F$  is expensive to evaluate and the number of calls to  $F$  is to be restricted, then use of C05AZF(\*) is recommended. Use of C05AZF(\*) is also recommended when the structure of the problem to be solved does not permit a simple function  $F$  to be written: the reverse communication facilities of C05AZF(\*) are more flexible than the direct communication of  $F$  required by C05ADF.

#### 9. Example

The example program below calculates the zero of  $e^{-x}$  within the interval  $[0,1]$  to approximately 5 decimal places.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

C05NBF(3NAG)

Foundation Library (12/10/92)

C05NBF(3NAG)

C05 -- Roots of One or More Transcendental Equations

C05NBF

## C05NBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

C05NBF is an easy-to-use routine to find a solution of a system of nonlinear equations by a modification of the Powell hybrid method.

## 2. Specification

```

SUBROUTINE C05NBF (FCN, N, X, FVEC, XTOL, WA, LWA, IFAIL)
 INTEGER N, LWA, IFAIL
 DOUBLE PRECISION X(N), FVEC(N), XTOL, WA(LWA)
 EXTERNAL FCN

```

## 3. Description

The system of equations is defined as:

$$f(x_1, x_2, \dots, x_n) = 0, \text{ for } i=1, 2, \dots, n.$$

C05NBF is based upon the MINPACK routine HYBRD1 (More et al [1]). It chooses the correction at each step as a convex combination of the Newton and scaled gradient directions. Under reasonable conditions this guarantees global convergence for starting points far from the solution and a fast rate of convergence. The Jacobian is updated by the rank-1 method of Broyden. At the starting point the Jacobian is approximated by forward differences, but these are not used again until the rank-1 method fails to produce satisfactory progress. For more details see Powell [2].

Equations. (ed P Rabinowitz) Gordon and Breach.

## 5. Parameters

- 1: FCN -- SUBROUTINE, supplied by the user.

External Procedure

FCN must return the values of the functions  $f_i$  at a point  $x_i$ .

Its specification is:

```
SUBROUTINE FCN (N, X, FVEC, IFLAG)
 INTEGER N, IFLAG
 DOUBLE PRECISION X(N), FVEC(N)
```

- 1: N -- INTEGER Input  
 On entry: the number of equations, n.
- 2: X(N) -- DOUBLE PRECISION array Input  
 On entry: the components of the point  $x$  at which the functions must be evaluated.
- 3: FVEC(N) -- DOUBLE PRECISION array Output  
 On exit: the function values  $f_i(x)$  (unless IFLAG is set to a negative value by FCN).
- 4: IFLAG -- INTEGER Input/Output  
 On entry: IFLAG > 0. On exit: in general, IFLAG should not be reset by FCN. If, however, the user wishes to terminate execution (perhaps because some illegal point  $X$  has been reached), then IFLAG should be set to a negative integer. This value will be returned through IFAIL.

FCN must be declared as EXTERNAL in the (sub)program from which C05NBF is called. Parameters denoted as Input must not be changed by this procedure.

- 2: N -- INTEGER Input  
 On entry: the number of equations, n. Constraint:  $N > 0$ .
- 3: X(N) -- DOUBLE PRECISION array Input/Output  
 On entry: an initial guess at the solution vector. On exit: the final estimate of the solution vector.
- 4: FVEC(N) -- DOUBLE PRECISION array Output

On exit: the function values at the final point, X.

- 5: XTOL -- DOUBLE PRECISION Input  
 On entry: the accuracy in X to which the solution is required. Suggested value: the square root of the machine precision. Constraint: XTOL  $\geq$  0.0.
- 6: WA(LWA) -- DOUBLE PRECISION array Workspace
- 7: LWA -- INTEGER Input  
 On entry: the dimension of the array WA. Constraint: LWA  $\geq$  N\*(3\*N+13)/2.
- 8: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL < 0

The user has set IFLAG negative in FCN. The value of IFAIL will be the same as the user's setting of IFLAG.

IFAIL = 1

On entry N  $\leq$  0,

or XTOL < 0.0,

or LWA < N\*(3\*N+13)/2.

IFAIL = 2

There have been at least 200\*(N+1) evaluations of FCN. Consider restarting the calculation from the final point held in X.

IFAIL = 3

No further improvement in the approximate solution X is

possible; XTOL is too small.

IFAIL= 4

The iteration is not making good progress. This failure exit may indicate that the system does not have a zero, or that the solution is very close to the origin (see Section 7). Otherwise, rerunning C05NBF from a different starting point may avoid the region of difficulty.

## 7. Accuracy

If  $\hat{x}$  is the true solution, C05NBF tries to ensure that

$$||\hat{x} - x|| \leq XTOL * ||\hat{x}||.$$

If this condition is satisfied with  $XTOL = 10^{-k}$ , then the larger components of  $x$  have  $k$  significant decimal digits. There is a danger that the smaller components of  $x$  may have large relative errors, but the fast rate of convergence of C05NBF usually avoids this possibility.

If XTOL is less than machine precision, and the above test is satisfied with the machine precision in place of XTOL, then the routine exits with IFAIL = 3.

Note: this convergence test is based purely on relative error, and may not indicate convergence if the solution is very close to the origin.

The test assumes that the functions are reasonably well behaved. If this condition is not satisfied, then C05NBF may incorrectly indicate convergence. The validity of the answer can be checked, for example, by rerunning C05NBF with a tighter tolerance.

## 8. Further Comments

The time required by C05NBF to solve a given problem depends on  $n$ , the behaviour of the functions, the accuracy requested and the starting point. The number of arithmetic operations executed by

C05NBF to process each call of FCN is about  $11.5 * n^2$ . Unless FCN can be evaluated quickly, the timing of C05NBF will be strongly influenced by the time spent in FCN.

Ideally the problem should be scaled so that at the solution the function values are of comparable magnitude.

### 9. Example

To determine the values  $x_1, \dots, x_9$  which satisfy the tridiagonal equations:

$$\begin{aligned} (3-2x_1)x_1 - 2x_2 &= -1 \\ -x_i - 1 + (3-2x_i)x_i - 2x_{i+1} &= -1, \quad i=2,3,\dots,8 \\ -x_8 + (3-2x_8)x_8 &= -1. \end{aligned}$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

C05PBF(3NAG)      Foundation Library (12/10/92)      C05PBF(3NAG)

C05 -- Roots of One or More Transcendental Equations      C05PBF  
C05PBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

C05PBF is an easy-to-use routine to find a solution of a system of nonlinear equations by a modification of the Powell hybrid method. The user must provide the Jacobian.

### 2. Specification

```

SUBROUTINE C05PBF (FCN, N, X, FVEC, FJAC, LDFJAC, XTOL,
1 WA, LWA, IFAIL)
INTEGER N, LDFJAC, LWA, IFAIL
```

```

 DOUBLE PRECISION X(N), FVEC(N), FJAC(LDFJAC,N), XTOL, WA
1 (LWA)
 EXTERNAL FCN

```

### 3. Description

The system of equations is defined as:

$$f(x_1, x_2, \dots, x_n) = 0, \quad i=1, 2, \dots, n.$$

C05PBF is based upon the MINPACK routine HYBRJ1 (More et al [1]). It chooses the correction at each step as a convex combination of the Newton and scaled gradient directions. Under reasonable conditions this guarantees global convergence for starting points far from the solution and a fast rate of convergence. The Jacobian is updated by the rank-1 method of Broyden. At the starting point the Jacobian is calculated, but it is not recalculated until the rank-1 method fails to produce satisfactory progress. For more details see Powell [2].

### 4. References

- [1] More J J, Garbow B S and Hillstom K E User Guide for MINPACK-1. Technical Report ANL-80-74. Argonne National Laboratory.
- [2] Powell M J D (1970) A Hybrid Method for Nonlinear Algebraic Equations. Numerical Methods for Nonlinear Algebraic Equations. (ed P Rabinowitz) Gordon and Breach.

### 5. Parameters

- 1: FCN -- SUBROUTINE, supplied by the user.

External Procedure

Depending upon the value of IFLAG, FCN must either return the values of the functions  $f_i$  at a point  $x$  or return the

Jacobian at  $x$ .

Its specification is:

```

 SUBROUTINE FCN (N, X, FVEC, FJAC, LDFJAC, IFLAG)
 INTEGER N, LDFJAC, IFLAG
 DOUBLE PRECISION X(N), FVEC(N), FJAC(LDFJAC,N)

```

- 1: N -- INTEGER Input  
On entry: the number of equations, n.
  
- 2: X(N) -- DOUBLE PRECISION array Input  
On entry: the components of the point x at which the functions or the Jacobian must be evaluated.
  
- 3: FVEC(N) -- DOUBLE PRECISION array Output  
On exit: if IFLAG = 1 on entry, FVEC must contain the function values  $f(x)$  (unless IFLAG is set to a negative value by FCN). If IFLAG = 2 on entry, FVEC must not be changed.
  
- 4: FJAC(LDFJAC,N) -- DOUBLE PRECISION array Output  
On exit: if IFLAG = 2 on entry, FJAC(i,j) must contain the value of  $\frac{\partial f_i}{\partial x_j}$  at the point x, for  $i,j=1,2,\dots,n$  (unless IFLAG is set to a negative value by FCN).  
  
If IFLAG = 1 on entry, FJAC must not be changed.
  
- 5: LDFJAC -- INTEGER Input  
On entry: the first dimension of FJAC.
  
- 6: IFLAG -- INTEGER Input/Output  
On entry: IFLAG = 1 or 2:  
    if IFLAG = 1, FVEC is to be updated;  
    if IFLAG = 2, FJAC is to be updated.  
On exit: in general, IFLAG should not be reset by FCN. If, however, the user wishes to terminate execution (perhaps because some illegal point x has been reached) then IFLAG should be set to a negative integer. This value will be returned through IFAIL.  
FCN must be declared as EXTERNAL in the (sub)program from which C05PBF is called. Parameters denoted as Input must not be changed by this procedure.
  
- 2: N -- INTEGER Input  
On entry: the number of equations, n. Constraint:  $N > 0$ .
  
- 3: X(N) -- DOUBLE PRECISION array Input/Output

On entry: an initial guess at the solution vector. On  
exit: the final estimate of the solution vector.

- 4: FVEC(N) -- DOUBLE PRECISION array Output  
On exit: the function values at the final point, X.
- 5: FJAC(LDFJAC,N) -- DOUBLE PRECISION array Output  
On exit: the orthogonal matrix Q produced by the QR  
factorization of the final approximate Jacobian.
- 6: LDFJAC -- INTEGER Input  
On entry:  
the first dimension of the array FJAC as declared in the  
(sub)program from which C05PBF is called.  
Constraint: LDFJAC  $\geq$  N.
- 7: XTOL -- DOUBLE PRECISION Input  
On entry: the accuracy in X to which the solution is  
required. Suggested value: the square root of the machine  
precision. Constraint: XTOL  $\geq$  0.0.
- 8: WA(LWA) -- DOUBLE PRECISION array Workspace
- 9: LWA -- INTEGER Input  
On entry: the dimension of the array WA. Constraint:  
LWA  $\geq$  N\*(N+13)/2.
- 10: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not  
familiar with this parameter (described in the Essential  
Introduction) the recommended value is 0.  
  
On exit: IFAIL = 0 unless the routine detects an error (see  
Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are  
output on the current error message unit (as defined by X04AAF).

IFAIL < 0

A negative value of IFAIL indicates an exit from C05PBF  
because the user has set IFLAG negative in FCN. The value of  
IFAIL will be the same as the user's setting of IFLAG.

IFAIL= 1

On entry  $N \leq 0$ ,

or  $LDFJAC < N$ ,

or  $XTOL < 0.0$ ,

or  $LWA < N*(N+13)/2$ .

IFAIL= 2

There have been  $100*(N+1)$  evaluations of the functions.  
Consider restarting the calculation from the final point  
held in X.

IFAIL= 3

No further improvement in the approximate solution X is  
possible; XTOL is too small.

IFAIL= 4

The iteration is not making good progress. This failure exit  
may indicate that the system does not have a zero or that  
the solution is very close to the origin (see Section 7).  
Otherwise, rerunning C05PBF from a different starting point  
may avoid the region of difficulty.

## 7. Accuracy

If  $\hat{x}$  is the true solution, C05PBF tries to ensure that

$$\frac{\|\hat{x} - x\|}{2} \leq XTOL * \frac{\|\hat{x}\|}{2}.$$

If this condition is satisfied with  $XTOL=10^{-k}$ , then the larger  
components of  $x$  have  $k$  significant decimal digits. There is a  
danger that the smaller components of  $x$  may have large relative  
errors, but the fast rate of convergence of C05PBF usually avoids  
the possibility.

If XTOL is less than machine precision and the above test is  
satisfied with the machine precision in place of XTOL, then the  
routine exits with IFAIL = 3.

Note: this convergence test is based purely on relative error, and may not indicate convergence if the solution is very close to the origin.

The test assumes that the functions and Jacobian are coded consistently and that the functions are reasonably well behaved. If these conditions are not satisfied then C05PBF may incorrectly indicate convergence. The coding of the Jacobian can be checked using C05ZAF. If the Jacobian is coded correctly, then the validity of the answer can be checked by rerunning C05PBF with a tighter tolerance.

#### 8. Further Comments

The time required by C05PBF to solve a given problem depends on  $n$ , the behaviour of the functions, the accuracy requested and the starting point. The number of arithmetic operations executed by

2

C05PBF is about  $11.5 \cdot n$  to process each evaluation of the

3

functions and about  $1.3 \cdot n$  to process each evaluation of the Jacobian. Unless FCN can be evaluated quickly, the timing of C05PBF will be strongly influenced by the time spent in FCN.

Ideally the problem should be scaled so that, at the solution, the function values are of comparable magnitude.

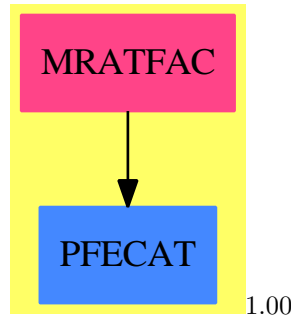

#### 9. Example

To determine the values  $x_1, \dots, x_9$  which satisfy the tridiagonal equations:

$$\begin{aligned} (3-2x_1)x_1 - 2x_2 &= -1 \\ -x_{i-1} + (3-2x_i)x_i - 2x_{i+1} &= -1, \quad i=2,3,\dots,8. \\ -x_8 + (3-2x_9)x_9 &= -1. \end{aligned}$$

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

C06 -- Summation of Series

Introduction -- C06

Chapter C06

Summation of Series

### 1. Scope of the Chapter

This chapter is concerned with calculating the discrete Fourier transform of a sequence of real or complex data values, and applying it to calculate convolutions and correlations.

### 2. Background to the Problems

#### 2.1. Discrete Fourier Transforms

##### 2.1.1. Complex transforms

Most of the routines in this chapter calculate the finite discrete Fourier transform (DFT) of a sequence of  $n$  complex numbers  $z_j$ , for  $j=0,1,\dots,n-1$ . The transform is defined by:

$$\hat{z}_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_j \exp(-i \frac{2\pi jk}{n}) \quad (1)$$

for  $k=0,1,\dots,n-1$ . Note that equation (1) makes sense for all

integral  $k$  and with this extension  $\hat{z}_k$  is periodic with period  $n$ ,

i.e.  $\hat{z}_k = \hat{z}_{k+n}$ , and in particular  $\hat{z}_{-k} = \hat{z}_{n-k}$ .

If we write  $z_j = x_j + iy_j$  and  $z_k = a_k + ib_k$ , then the definition of  $z_k$  may be written in terms of sines and cosines as:

$$a_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} \left( x_j \cos\left(\frac{2(\pi)jk}{n}\right) + y_j \sin\left(\frac{2(\pi)jk}{n}\right) \right)$$

$$b_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} \left( y_j \cos\left(\frac{2(\pi)jk}{n}\right) - x_j \sin\left(\frac{2(\pi)jk}{n}\right) \right).$$

The original data values  $z_j$  may conversely be recovered from the transform  $z_k$  by an inverse discrete Fourier transform:

$$z_j = \frac{1}{\sqrt{n}} \sum_{k=0}^{n-1} z_k \exp\left(+i \frac{2(\pi)jk}{n}\right) \quad (2)$$

for  $j=0,1,\dots,n-1$ . If we take the complex conjugate of (2), we

find that the sequence  $z_j$  is the DFT of the sequence  $\bar{z}_k$ . Hence

the inverse DFT of the sequence  $z_k$  may be obtained by: taking the

complex conjugates of the  $z_k$ ; performing a DFT; and taking the complex conjugates of the result.

Notes: definitions of the discrete Fourier transform vary. Sometimes (2) is used as the definition of the DFT, and (1) as

the definition of the inverse. Also the scale-factor of  $1/\sqrt{n}$  may be omitted in the definition of the DFT, and replaced by  $1/n$  in the definition of the inverse.

### 2.1.2. Real transforms

If the original sequence is purely real valued, i.e.  $z_j = x_j$ , then

$$\hat{z}_k = a_k + ib_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} x_j \exp(-i \frac{2(\pi)jk}{n})$$

and  $\hat{z}_{n-k}$  is the complex conjugate of  $\hat{z}_k$ . Thus the DFT of a real sequence is a particular type of complex sequence, called a Hermitian sequence, or half-complex or conjugate symmetric with the properties:

$$a_{n-k} = a_k, \quad b_{n-k} = -b_k, \quad b_0 = 0 \text{ and, if } n \text{ is even, } b_{n/2} = 0.$$

Thus a Hermitian sequence of  $n$  complex data values can be represented by only  $n$ , rather than  $2n$ , independent real values. This can obviously lead to economies in storage, the following scheme being used in this chapter: the real parts  $a_k$  for

$0 \leq k \leq n/2$  are stored in normal order in the first  $n/2+1$  locations of an array  $X$  of length  $n$ ; the corresponding non-zero imaginary parts are stored in reverse order in the remaining locations of  $X$ . In other words, if  $X$  is declared with bounds  $(0:n-1)$  in the

user's (sub)program, the real and imaginary parts of  $\hat{z}_k$  are

stored as follows:

|        | if $n=2s$ | if $n=2s-1$ |
|--------|-----------|-------------|
| $X(0)$ | $a_0$     | $a_0$       |
|        | $0$       | $0$         |
| $X(1)$ | $a_1$     | $a_1$       |
|        | $1$       | $1$         |

$$\begin{array}{rcl}
X(2) & a & a \\
& 2 & 2 \\
. & . & . \\
. & . & . \\
. & . & . \\
X(s-1) & a & a \\
& s-1 & s-1 \\
X(s) & a & b \\
& s & s-1 \\
X(s+1) & b & b \\
& s-1 & s-2 \\
. & . & . \\
. & . & . \\
. & . & . \\
X(n-2) & b & b \\
& 2 & 2 \\
X(n-1) & b & b \\
& 1 & 1
\end{array}$$

$$\text{Hence } x_j = \frac{1}{\sqrt{n}} \sum_{k=0}^{n/2-1} \left( a \cos\left(\frac{2(\pi)jk}{n}\right) - b \sin\left(\frac{2(\pi)jk}{n}\right) + a \right)$$

where  $a_{n/2} = 0$  if  $n$  is odd.

### 2.1.3. Fourier integral transforms

The usual application of the discrete Fourier transform is that of obtaining an approximation of the Fourier integral transform

$$F(s) = \int_{-\infty}^{+\infty} f(t) \exp(-i2(\pi)st) dt$$

when  $f(t)$  is negligible outside some region  $(0, c)$ . Dividing the region into  $n$  equal intervals we have

$$F(s) \sim \frac{c}{n} \sum_{j=0}^{n-1} f_j \exp(-i2(\pi)sjc/n)$$

and so

$$F_k \sim \frac{c}{n} \sum_{j=0}^{n-1} f_j \exp(-i2(\pi)jk/n)$$

for  $k=0, 1, \dots, n-1$ , where  $f_j = f(jc/n)$  and  $F_k = F(k/c)$ .

Hence the discrete Fourier transform gives an approximation to the Fourier integral transform in the region  $s=0$  to  $s=n/c$ .

If the function  $f(t)$  is defined over some more general interval  $(a, b)$ , then the integral transform can still be approximated by the discrete transform provided a shift is applied to move the point  $a$  to the origin.

#### 2.1.4. Convolutions and correlations

One of the most important applications of the discrete Fourier transform is to the computation of the discrete convolution or correlation of two vectors  $x$  and  $y$  defined (as in Brigham [1]) by:

$$\text{convolution: } z_k = \sum_{j=0}^{n-1} x_j y_{k-j}$$

$$\text{correlation: } w_k = \sum_{j=0}^{n-1} x_j y_{k+j}$$

(Here  $x$  and  $y$  are assumed to be periodic with period  $n$ .)

Under certain circumstances (see Brigham [1]) these can be used as approximations to the convolution or correlation integrals defined by:

$$z(s) = \frac{\int_{-\infty}^{+\infty} x(t)y(s-t)dt}{\int_{-\infty}^{+\infty} x(t)y(s-t)dt}$$

and

$$w(s) = \frac{\int_{-\infty}^{+\infty} x(t)y(s+t)dt}{\int_{-\infty}^{+\infty} x(t)y(s+t)dt}, \quad -\infty < s < +\infty.$$

For more general advice on the use of Fourier transforms, see Hamming [2]; more detailed information on the fast Fourier transform algorithm can be found in Van Loan [3] and Brigham [1].

## 3. Recommendations on Choice and Use of Routines

### 3.1. One-dimensional Fourier Transforms

The choice of routine is determined first of all by whether the data values constitute a real, Hermitian or general complex sequence. It is wasteful of time and storage to use an inappropriate routine.

Two groups, each of three routines, are provided

|                              | Group 1 | Group 2 |
|------------------------------|---------|---------|
| Real sequences               | C06EAF  | C06FPF  |
| Hermitian sequences          | C06EBF  | C06FQF  |
| General complex<br>sequences | C06ECF  | C06FRF  |

Group 1 routines each compute a single transform of length  $n$ , without requiring any extra working storage. The Group 1 routines impose some restrictions on the value of  $n$ , namely that no prime factor of  $n$  may exceed 19 and the total number of prime factors (including repetitions) may not exceed 20 (though the latter

6

restriction only becomes relevant when  $n > 10$  ).

Group 2 routines are designed to perform several transforms in a single call, all with the same value of  $n$ . They do however require more working storage. Even on scalar processors, they may be somewhat faster than repeated calls to Group 1 routines because of reduced overheads and because they pre-compute and store the required values of trigonometric functions. Group 2 routines impose no practical restrictions on the value of  $n$ ; however the fast Fourier transform algorithm ceases to be 'fast' if applied to values of  $n$  which cannot be expressed as a product of small prime factors. All the above routines are particularly efficient if the only prime factors of  $n$  are 2, 3 or 5.

If extensive use is to be made of these routines, users who are concerned about efficiency are advised to conduct their own timing tests.

To compute inverse discrete Fourier transforms the above routines should be used in conjunction with the utility routines C06GBF, C06GCF and C06GQF which form the complex conjugate of a Hermitian or general sequence of complex data values.

## 3.2. Multi-dimensional Fourier Transforms

C06FUF computes a 2-dimensional discrete Fourier transform of a 2-dimensional sequence of complex data values. This is defined by

$$\hat{z} = \sum_{k=0}^{n_1-1} \sum_{j=0}^{n_2-1} z_{kj} \exp(-i \frac{2\pi j k}{n_1}) \exp(-i \frac{2\pi j k}{n_2}).$$

## 3.3. Convolution and Correlation

C06EKF computes either the discrete convolution or the discrete correlation of two real vectors.

## 3.4. Index

|                                           |        |

C06 -- Summation of Series C06EAF  
C06EAF -- NAG Foundation Library Routine Document

## 1. Purpose

## 2. Specification

```

SUBROUTINE C06EAF (X, N, IFAIL)
INTEGER N, IFAIL
DOUBLE PRECISION X(N)

```

### 3. Description

Given a sequence of  $n$  real data values  $x_j$ , for  $j=0,1,\dots,n-1$ , this routine calculates their discrete Fourier transform defined by:

$$z_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} x_j \exp(-i \frac{2(\pi)jk}{n}), \quad k=0,1,\dots,n-1.$$

(Note the scale factor of  $\frac{1}{\sqrt{n}}$  in this definition.) The

transformed values  $z_k$  are complex, but they form a Hermitian sequence (i.e.,  $z_{n-k}$  is the complex conjugate of  $z_k$ ), so they are completely determined by  $n$  real numbers (see also the Chapter Introduction).

To compute the inverse discrete Fourier transform defined by:

$$w_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} x_j \exp(+i \frac{2(\pi)jk}{n}),$$

this routine should be followed by a call of C06GBF to form the complex conjugates of the  $z_k$ .

The routine uses the fast Fourier transform (FFT) algorithm

(Brigham [1]). There are some restrictions on the value of  $n$  (see Section 5).

#### 4. References

- [1] Brigham E O (1973) The Fast Fourier Transform. Prentice-Hall.

#### 5. Parameters

- 1:  $X(N)$  -- DOUBLE PRECISION array Input/Output  
 On entry: if  $X$  is declared with bounds  $(0:N-1)$  in the (sub) program from which C06EAF is called, then  $X(j)$  must contain  $x_j$ , for  $j=0,1,\dots,n-1$ . On exit: the discrete Fourier transform stored in Hermitian form. If the components of the transform  $z_k$  are written as  $a_k + ib_k$ , and if  $X$  is declared with bounds  $(0:N-1)$  in the (sub)program from which C06EAF is called, then for  $0 \leq k \leq n/2$ ,  $a_k$  is contained in  $X(k)$ , and for  $1 \leq k \leq (n-1)/2$ ,  $b_k$  is contained in  $X(n-k)$ . (See also Section 2.1.2 of the Chapter Introduction, and the Example Program.)
- 2:  $N$  -- INTEGER Input  
 On entry: the number of data values,  $n$ . The largest prime factor of  $N$  must not exceed 19, and the total number of prime factors of  $N$ , counting repetitions, must not exceed 20. Constraint:  $N > 1$ .
- 3: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

At least one of the prime factors of  $N$  is greater than 19.

```
IFAIL= 2
 N has more than 20 prime factors.
```

```
IFAIL= 3
 N <= 1.
```

#### 7. Accuracy

Some indication of accuracy can be obtained by performing a subsequent inverse transform and comparing the results with the original sequence (in exact arithmetic they would be identical).

#### 8. Further Comments

The time taken by the routine is approximately proportional to  $n \log n$ , but also depends on the factorization of  $n$ . The routine is somewhat faster than average if the only prime factors of  $n$  are 2, 3 or 5; and fastest of all if  $n$  is a power of 2.

On the other hand, the routine is particularly slow if  $n$  has several unpaired prime factors, i.e., if the 'square-free' part of  $n$  has several factors. For such values of  $n$ , routine C06FAF(\*) (which requires an additional  $n$  elements of workspace) is considerably faster.

#### 9. Example

This program reads in a sequence of real data values, and prints their discrete Fourier transform (as computed by C06EAF), after expanding it from Hermitian form into a full complex sequence.

It then performs an inverse transform using C06GBF and C06EBF, and prints the sequence so obtained alongside the original data values.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

C06EBF calculates the discrete Fourier transform of a Hermitian sequence of  $n$  complex data values. (No extra workspace required.)

### 2. Specification

```
SUBROUTINE C06EBF (X, N, IFAIL)
 INTEGER N, IFAIL
 DOUBLE PRECISION X(N)
```

### 3. Description

Given a Hermitian sequence of  $n$  complex data values  $z_j$  (i.e., a sequence such that  $z_0$  is real and  $z_{n-j}$  is the complex conjugate of  $z_j$ , for  $j=1,2,\dots,n-1$ ) this routine calculates their discrete Fourier transform defined by:

$$\hat{x}_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_j \exp(-i \frac{2(\pi)jk}{n}), \quad k=0,1,\dots,n-1.$$

(Note the scale factor of  $\frac{1}{\sqrt{n}}$  in this definition.) The

transformed values  $\hat{x}_k$  are purely real (see also the Chapter Introduction).

To compute the inverse discrete Fourier transform defined by:

$$x_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} \hat{x}_j \exp(i \frac{2(\pi)jk}{n}), \quad k=0,1,\dots,n-1.$$

$$y = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_j \exp\left(+i \frac{2(\pi)jk}{n}\right),$$

this routine should be preceded by a call of C06GBF to form the complex conjugates of the  $z_j$ .

The routine uses the fast Fourier transform (FFT) algorithm (Brigham [1]). There are some restrictions on the value of  $n$  (see Section 5).

#### 4. References

- [1] Brigham E O (1973) The Fast Fourier Transform. Prentice-Hall.

#### 5. Parameters

- 1: X(N) -- DOUBLE PRECISION array Input/Output  
 On entry: the sequence to be transformed stored in Hermitian form. If the data values  $z_j$  are written as  $x_j + iy_j$ , and if X is declared with bounds (0:N-1) in the subroutine from which C06EBF is called, then for  $0 \leq j \leq n/2$ ,  $x_j$  is contained in X(j), and for  $1 \leq j \leq (n-1)/2$ ,  $y_j$  is contained in X(n-j). (See also Section 2.1.2 of the Chapter Introduction and the Example Program.) On exit: the components of the discrete Fourier transform  $\hat{x}_k$ . If X is declared with bounds (0:N-1) in the (sub)program from which C06EBF is called, then  $\hat{x}_k$  is stored in X(k), for  $k=0,1,\dots,n-1$ .
- 2: N -- INTEGER Input  
 On entry: the number of data values, n. The largest prime factor of N must not exceed 19, and the total number of prime factors of N, counting repetitions, must not exceed 20. Constraint:  $N > 1$ .
- 3: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

At least one of the prime factors of N is greater than 19.

IFAIL= 2

N has more than 20 prime factors.

IFAIL= 3

$N \leq 1$ .

## 7. Accuracy

Some indication of accuracy can be obtained by performing a subsequent inverse transform and comparing the results with the original sequence (in exact arithmetic they would be identical).

## 8. Further Comments

The time taken by the routine is approximately proportional to  $n \cdot \log n$ , but also depends on the factorization of  $n$ . The routine is somewhat faster than average if the only prime factors of  $n$  are 2, 3 or 5; and fastest of all if  $n$  is a power of 2.

On the other hand, the routine is particularly slow if  $n$  has several unpaired prime factors, i.e., if the 'square-free' part of  $n$  has several factors. For such values of  $n$ , routine C06FBF(\*) (which requires an additional  $n$  elements of workspace) is considerably faster.

## 9. Example

This program reads in a sequence of real data values which is assumed to be a Hermitian sequence of complex data values stored in Hermitian form. The input sequence is expanded into a full complex sequence and printed alongside the original sequence. The discrete Fourier transform (as computed by C06EBF) is printed

The program then performs an inverse transform using C06EAF and C06GBF, and prints the sequence so obtained alongside the original data values.

#### 5. Parameters

- 1: X(N) -- DOUBLE PRECISION array Input/Output  
 On entry: if X is declared with bounds (0:N-1) in the (sub) program from which C06ECF is called, then X(j) must contain  $x_j$ , the real part of  $z_j$ , for  $j=0,1,\dots,n-1$ . On exit: the real parts  $a_k$  of the components of the discrete Fourier transform. If X is declared with bounds (0:N-1) in the (sub) program from which C06ECF is called, then  $a_k$  is contained in X(k), for  $k=0,1,\dots,n-1$ .
- 2: Y(N) -- DOUBLE PRECISION array Input/Output  
 On entry: if Y is declared with bounds (0:N-1) in the (sub) program from which C06ECF is called, then Y(j) must contain  $y_j$ , the imaginary part of  $z_j$ , for  $j=0,1,\dots,n-1$ . On exit:

the imaginary parts  $b_j$  of the components of the discrete  
 $k$   
 Fourier transform. If  $Y$  is declared with bounds  $(0:N-1)$  in  
 the (sub)program from which C06ECF is called, then  $b_k$  is  
 $k$   
 contained in  $Y(k)$ , for  $k=0,1,\dots,n-1$ .

3: N -- INTEGER Input  
 On entry: the number of data values,  $n$ . The largest prime  
 factor of  $N$  must not exceed 19, and the total number of  
 prime factors of  $N$ , counting repetitions, must not exceed  
 20. Constraint:  $N > 1$ .

4: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not  
 familiar with this parameter (described in the Essential  
 Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see  
 Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 At least one of the prime factors of  $N$  is greater than 19.

IFAIL= 2  
 $N$  has more than 20 prime factors.

IFAIL= 3  
 $N \leq 1$ .

## 7. Accuracy

Some indication of accuracy can be obtained by performing a  
 subsequent inverse transform and comparing the results with the  
 original sequence (in exact arithmetic they would be identical).

## 8. Further Comments

The time taken by the routine is approximately proportional to  
 $n \log n$ , but also depends on the factorization of  $n$ . The routine  
 is somewhat faster than average if the only prime factors of  $n$

On the other hand, the routine is particularly slow if  $n$  has several unpaired prime factors, i.e., if the 'square-free' part of  $n$  has several factors. For such values of  $n$ , routine C06FCF(\*) (which requires an additional  $n$  real elements of workspace) is considerably faster.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

### 3. Description

This routine computes:

if JOB =1, the discrete convolution of x and y, defined by:

$$z_k = \sum_{j=0}^{n-1} x_j y_{k-j} = \sum_{j=0}^{n-1} x_{k-j} y_j ;$$

if JOB =2, the discrete correlation of x and y defined by:

$$w_k = \sum_{j=0}^{n-1} x_j y_{k+j} .$$

Here x and y are real vectors, assumed to be periodic, with period n, i.e.,  $x_j = x_{j+n} = \dots$ ; z and w are then also periodic with period n.

Note: this usage of the terms 'convolution' and 'correlation' is taken from Brigham [1]. The term 'convolution' is sometimes used to denote both these computations.

If  $\hat{x}$ ,  $\hat{y}$ ,  $\hat{z}$  and  $\hat{w}$  are the discrete Fourier transforms of these sequences,

$$\hat{x}_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} x_j \exp(-i \frac{2(\pi)jk}{n}), \text{ etc,}$$

$$\text{then } \hat{z}_k = \sqrt{n} \hat{x}_k \hat{y}_k$$

$$\text{and } \hat{w}_k = \sqrt{n} \hat{x}_k \hat{y}_{-k}$$

(the bar denoting complex conjugate).

This routine calls the same auxiliary routines as C06EAF and C06EBF to compute discrete Fourier transforms, and there are some restrictions on the value of  $n$ .

#### 5. Parameters

1: JOB -- INTEGER Input

On entry: the computation to be performed:

$$\begin{array}{c} n-1 \\ \text{--} \\ \text{if JOB} = 1, z = \sum_{k=0}^{n-1} x_k y_{k-j} \quad (\text{convolution}); \\ \text{--} \\ j=0 \end{array}$$

$$\begin{array}{c} n-1 \\ \text{--} \\ \text{if JOB} = 2, w = \sum_{k=0}^{n-1} x_k y_{k+j} \quad (\text{correlation}). \\ \text{--} \\ j=0 \end{array}$$

Constraint: JOB = 1 or 2.

2: X(N) -- DOUBLE PRECISION array Input/Output

On entry: the elements of one period of the vector  $x$ . If  $X$  is declared with bounds (0:N-1) in the (sub)program from which C06EKF is called, then  $X(j)$  must contain  $x_j$ , for  $j=0,1,\dots,n-1$ . On exit: the corresponding elements of the discrete convolution or correlation.

3: Y(N) -- DOUBLE PRECISION array Input/Output

On entry: the elements of one period of the vector  $y$ . If  $Y$  is declared with bounds (0:N-1) in the (sub)program from which C06EKF is called, then  $Y(j)$  must contain  $y_j$ , for  $j=0,1,\dots,n-1$ . On exit: the discrete Fourier transform of the convolution or correlation returned in the array  $X$ ; the transform is stored in Hermitian form, exactly as described in the document C06EAF.

4: N -- INTEGER Input  
 On entry: the number of values, n, in one period of the vectors X and Y. The largest prime factor of N must not exceed 19, and the total number of prime factors of N, counting repetitions, must not exceed 20. Constraint:  $N > 1$ .

5: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 At least one of the prime factors of N is greater than 19.

IFAIL= 2  
 N has more than 20 prime factors.

IFAIL= 3  
 $N \leq 1$ .

IFAIL= 4  
 JOB /= 1 or 2.

#### 7. Accuracy

The results should be accurate to within a small multiple of the machine precision.

#### 8. Further Comments

The time taken by the routine is approximately proportional to  $n \cdot \log n$ , but also depends on the factorization of n. The routine is faster than average if the only prime factors are 2, 3 or 5; and fastest of all if n is a power of 2.

The routine is particularly slow if n has several unpaired prime factors, i.e., if the 'square free' part of n has several factors. For such values of n, routine C06FKF(\*) is considerably

## 9. Example

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

|              |                               |              |
|--------------|-------------------------------|--------------|
| C06FPF(3NAG) | Foundation Library (12/10/92) | C06FPF(3NAG) |
|--------------|-------------------------------|--------------|

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

C06FPF computes the discrete Fourier transforms of m sequences, each containing n real data values. This routine is designed to be particularly efficient on vector processors.

```

SUBROUTINE C06FPF (M, N, X, INIT, TRIG, WORK, IFAIL)
 INTEGER M, N, IFAIL
 DOUBLE PRECISION X(M*N), TRIG(2*N), WORK(M*N)
 CHARACTER*1 INIT

```

Given  $m$  sequences of  $n$  real data values  $x_j^p$ , for  $j=0,1,\dots,n-1$ ;  
 $p=1,2,\dots,m$ , this routine simultaneously calculates the Fourier  
transforms of all the sequences defined by:

$$z_k^{(p)} = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} x_j \exp(-i \frac{2(\pi)jk}{n}), \quad k=0,1,\dots,n-1; \quad p=1,2,\dots,m.$$

(Note the scale factor  $\frac{1}{\sqrt{n}}$  in this definition.)

$\sqrt{n}$

The transformed values  $z_k^{(p)}$  are complex, but for each value of  $p$

the  $z_k^{(p)}$  form a Hermitian sequence (i.e.,  $z_{n-k}^{(p)}$  is the complex conjugate of  $z_k^{(p)}$ ), so they are completely determined by  $mn$  real numbers (see also the Chapter Introduction).

The discrete Fourier transform is sometimes defined using a positive sign in the exponential term:

$$z_k^{(p)} = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} x_j \exp(+i \frac{2(\pi)jk}{n}).$$

To compute this form, this routine should be followed by a call to C06GQF to form the complex conjugates of the  $z_k^{(p)}$ .

The routine uses a variant of the fast Fourier transform (FFT) algorithm (Brigham [1]) known as the Stockham self-sorting algorithm, which is described in Temperton [2]. Special coding is provided for the factors 2, 3, 4, 5 and 6. This routine is designed to be particularly efficient on vector processors, and it becomes especially fast as  $M$ , the number of transforms to be computed in parallel, increases.

### 5. Parameters

- 1: M -- INTEGER Input  
 On entry: the number of sequences to be transformed, m.  
 Constraint: M ≥ 1.
  
- 2: N -- INTEGER Input  
 On entry: the number of real values in each sequence, n.  
 Constraint: N ≥ 1.
  
- 3: X(M,N) -- DOUBLE PRECISION array Input/Output  
 On entry: the data must be stored in X as if in a two-dimensional array of dimension (1:M,0:N-1); each of the m sequences is stored in a row of the array. In other words, if the data values of the pth sequence to be transformed are denoted by  $x_j^p$ , for  $j=0,1,\dots,n-1$ , then the mn elements of the array X must contain the values
 

|         |         |         |             |         |         |         |             |         |         |         |         |             |
|---------|---------|---------|-------------|---------|---------|---------|-------------|---------|---------|---------|---------|-------------|
| 1       | 2       | ...     | m           | 1       | 2       | ...     | m           | 1       | 2       | ...     | m       |             |
| $x_0^1$ | $x_1^1$ | $\dots$ | $x_{n-1}^1$ | $x_0^2$ | $x_1^2$ | $\dots$ | $x_{n-1}^2$ | $\dots$ | $x_0^m$ | $x_1^m$ | $\dots$ | $x_{n-1}^m$ |

  
 On exit: the m discrete Fourier transforms stored as if in a two-dimensional array of dimension (1:M,0:N-1). Each of the m transforms is stored in a row of the array in Hermitian form, overwriting the corresponding original sequence. If the n components of the discrete Fourier transform  $z_k^p$  are written as  $a_k^p + ib_k^p$ , then for  $0 \leq k \leq n/2$ ,  $a_k^p$  is contained in  $X(p,k)$ , and for  $1 \leq k \leq (n-1)/2$ ,  $b_k^p$  is contained in  $X(p,n-k)$ . (See also Section 2.1.2 of the Chapter Introduction.)
  
- 4: INIT -- CHARACTER\*1 Input  
 On entry: if the trigonometric coefficients required to compute the transforms are to be calculated by the routine

and stored in the array TRIG, then INIT must be set equal to 'I' (Initial call).

If INIT contains 'S' (Subsequent call), then the routine assumes that trigonometric coefficients for the specified value of  $n$  are supplied in the array TRIG, having been calculated in a previous call to one of C06FPF, C06FQF or C06FRF.

If INIT contains 'R' (Restart then the routine assumes that trigonometric coefficients for the particular value of  $n$  are supplied in the array TRIG, but does not check that C06FPF, C06FQF or C06FRF have previously been called. This option allows the TRIG array to be stored in an external file, read in and re-used without the need for a call with INIT equal to 'I'. The routine carries out a simple test to check that the current value of  $n$  is consistent with the array TRIG. Constraint: INIT = 'I', 'S' or 'R'.

- 5: TRIG(2\*N) -- DOUBLE PRECISION array Input/Output  
 On entry: if INIT = 'S' or 'R', TRIG must contain the required coefficients calculated in a previous call of the routine. Otherwise TRIG need not be set. On exit: TRIG contains the required coefficients (computed by the routine if INIT = 'I').
- 6: WORK(M\*N) -- DOUBLE PRECISION array Workspace
- 7: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry  $M < 1$ .

IFAIL= 2  
N < 1.

IFAIL= 3  
INIT is not one of 'I', 'S' or 'R'.

IFAIL= 4  
INIT = 'S', but none of C06FPF, C06FQF or C06FRF has  
previously been called.

IFAIL= 5  
INIT = 'S' or 'R', but the array TRIG and the current value  
of N are inconsistent.

#### 7. Accuracy

Some indication of accuracy can be obtained by performing a  
subsequent inverse transform and comparing the results with the  
original sequence (in exact arithmetic they would be identical).

#### 8. Further Comments

The time taken by the routine is approximately proportional to  
 $nm \cdot \log n$ , but also depends on the factors of  $n$ . The routine is  
fastest if the only prime factors of  $n$  are 2, 3 and 5, and is  
particularly slow if  $n$  is a large prime, or has large prime  
factors.

#### 9. Example

This program reads in sequences of real data values and prints  
their discrete Fourier transforms (as computed by C06FPF). The  
Fourier transforms are expanded into full complex form using  
C06GSF and printed. Inverse transforms are then calculated by  
calling C06GQF followed by C06FQF showing that the original  
sequences are restored.

The example program is not reproduced here. The source code for  
all example programs is distributed with the NAG Foundation  
Library software and should be available on-line.

C06FQF(3NAG)

Foundation Library (12/10/92)

C06FQF(3NAG)

C06 -- Summation of Series C06FQF  
 C06FQF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

C06FQF computes the discrete Fourier transforms of  $m$  Hermitian sequences, each containing  $n$  complex data values. This routine is designed to be particularly efficient on vector processors.

### 2. Specification

```
SUBROUTINE C06FQF (M, N, X, INIT, TRIG, WORK, IFAIL)
 INTEGER M, N, IFAIL
 DOUBLE PRECISION X(M*N), TRIG(2*N), WORK(M*N)
 CHARACTER*1 INIT
```

### 3. Description

Given  $m$  Hermitian sequences of  $n$  complex data values  $z_j^p$ , for  $j=0,1,\dots,n-1$ ;  $p=1,2,\dots,m$ , this routine simultaneously calculates the Fourier transforms of all the sequences defined by:

$$x_k^p = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_j^p \exp(-i \frac{2(\pi)jk}{n}), \quad k=0,1,\dots,n-1; \quad p=1,2,\dots,m.$$

(Note the scale factor  $\frac{1}{\sqrt{n}}$  in this definition.)

$\sqrt{n}$

The transformed values are purely real (see also the Chapter Introduction).

The discrete Fourier transform is sometimes defined using a

positive sign in the exponential term

$$x_k = \frac{1}{\sqrt{n}} \sum_{j=0}^{n-1} z_j^* \exp(+i \frac{2(\pi)jk}{n}).$$

To compute this form, this routine should be preceded by a call to C06GQF to form the complex conjugates of the  $z_j^*$ .

The routine uses a variant of the fast Fourier transform (FFT) algorithm (Brigham [1]) known as the Stockham self-sorting algorithm, which is described in Temperton [2]. Special code is included for the factors 2, 3, 4, 5 and 6. This routine is designed to be particularly efficient on vector processors, and it becomes especially fast as  $m$ , the number of transforms to be computed in parallel, increases.

#### 5. Parameters

- 1: M -- INTEGER Input  
On entry: the number of sequences to be transformed,  $m$ .  
Constraint:  $M \geq 1$ .
- 2: N -- INTEGER Input  
On entry: the number of data values in each sequence,  $n$ .  
Constraint:  $N \geq 1$ .
- 3: X(M,N) -- DOUBLE PRECISION array Input/Output  
On entry: the data must be stored in X as if in a two-dimensional array of dimension (1:M,0:N-1); each of the  $m$  sequences is stored in a row of the array in Hermitian form.  
If the  $n$  data values  $z_j^p$  are written as  $x + iy$ , then for  

$j$ 
 $j$ 
 $j$

$0 \leq j \leq n/2$ ,  $x_j^p$  is contained in  $X(p, j)$ , and for  $1 \leq j \leq (n-1)/2$ ,

$y_j^p$  is contained in  $X(p, n-j)$ . (See also Section 2.1.2 of the Chapter Introduction.) On exit: the components of the  $m$  discrete Fourier transforms, stored as if in a two-dimensional array of dimension  $(1:M, 0:N-1)$ . Each of the  $m$  transforms is stored as a row of the array, overwriting the corresponding original sequence. If the  $n$  components of the discrete Fourier transform are denoted by  $x_k^p$ , for  $k=0, 1, \dots, n-1$ , then the  $mn$  elements of the array  $X$  contain the values

$$\begin{matrix} x_{00}^1, x_{01}^1, \dots, x_{0n-1}^1, & x_{10}^1, x_{11}^1, \dots, x_{1n-1}^1, & \dots, & x_{m0}^1, x_{m1}^1, \dots, x_{mn-1}^1. \end{matrix}$$

- 4: INIT -- CHARACTER\*1 Input  
On entry: if the trigonometric coefficients required to compute the transforms are to be calculated by the routine and stored in the array TRIG, then INIT must be set equal to 'I' (Initial call).

If INIT contains 'S' (Subsequent call), then the routine assumes that trigonometric coefficients for the specified value of  $n$  are supplied in the array TRIG, having been calculated in a previous call to one of C06FPF, C06FQF or C06FRF.

If INIT contains 'R' (Restart), then the routine assumes that trigonometric coefficients for the particular value of  $N$  are supplied in the array TRIG, but does not check that C06FPF, C06FQF or C06FRF have previously been called. This option allows the TRIG array to be stored in an external file, read in and re-used without the need for a call with INIT equal to 'I'. The routine carries out a simple test to check that the current value of  $n$  is compatible with the array TRIG. Constraint: INIT = 'I', 'S' or 'R'.

- 5: TRIG(2\*N) -- DOUBLE PRECISION array Input/Output  
On entry: if INIT = 'S' or 'R', TRIG must contain the required coefficients calculated in a previous call of the routine. Otherwise TRIG need not be set. On exit: TRIG

contains the required coefficients (computed by the routine if `INIT = 'I'`).

6: `WORK(M*N)` -- DOUBLE PRECISION array Workspace

7: `IFAIL` -- INTEGER Input/Output

On entry: `IFAIL` must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: `IFAIL` = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry `IFAIL` = 0 or -1, explanatory error messages are output on the current error message unit (as defined by `X04AAF`).

`IFAIL`= 1

On entry `M` < 1.

`IFAIL`= 2

On entry `N` < 1.

`IFAIL`= 3

On entry `INIT` is not one of 'I', 'S' or 'R'.

`IFAIL`= 4

On entry `INIT` = 'S', but none of `C06FPF`, `C06FQF` and `C06FRF` has previously been called.

`IFAIL`= 5

On entry `INIT` = 'S' or 'R', but the array `TRIG` and the current value of `n` are inconsistent.

## 7. Accuracy

Some indication of accuracy can be obtained by performing a subsequent inverse transform and comparing the results with the original sequence (in exact arithmetic they would be identical).

## 8. Further Comments

The time taken by the routine is approximately proportional to

`nm*logn`, but also depends on the factors of `n`. The routine is fastest if the only prime factors of `n` are 2, 3 and 5, and is particularly slow if `n` is a large prime, or has large prime factors.

## 9. Example

This program reads in sequences of real data values which are assumed to be Hermitian sequences of complex data stored in Hermitian form. The sequences are expanded into full complex form using C06GSF and printed. The discrete Fourier transforms are then computed (using C06FQF) and printed out. Inverse transforms are then calculated by calling C06FPF followed by C06GQF showing that the original sequences are restored.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

#### 5. Parameters

1: M -- INTEGER Input  
 On entry: the number of sequences to be transformed, m.  
 Constraint: M >= 1.

2: N -- INTEGER Input  
 On entry: the number of complex values in each sequence, n.  
 Constraint: N >= 1.

3: X(M,N) -- DOUBLE PRECISION array Input/Output

4: Y(M,N) -- DOUBLE PRECISION array Input/Output  
 On entry: the real and imaginary parts of the complex data must be stored in X and Y respectively as if in a two-dimensional array of dimension (1:M,0:N-1); each of the m sequences is stored in a row of each array. In other words, if the real parts of the pth sequence to be transformed are denoted by  $x_j^p$ , for  $j=0,1,\dots,n-1$ , then the mn elements of the array X must contain the values

|          |          |         |          |          |          |         |          |         |             |             |         |             |
|----------|----------|---------|----------|----------|----------|---------|----------|---------|-------------|-------------|---------|-------------|
| 1        | 2        | ...     | m        | 1        | 2        | ...     | m        | 1       | 2           | ...         | m       |             |
| $x_{00}$ | $x_{01}$ | $\dots$ | $x_{0m}$ | $x_{10}$ | $x_{11}$ | $\dots$ | $x_{1m}$ | $\dots$ | $x_{n-1,0}$ | $x_{n-1,1}$ | $\dots$ | $x_{n-1,m}$ |

On exit: X and Y are overwritten by the real and imaginary parts of the complex transforms.

5: INIT -- CHARACTER\*1 Input  
 On entry: if the trigonometric coefficients required to compute the transforms are to be calculated by the routine and stored in the array TRIG, then INIT must be set equal to 'I' (Initial call).

If INIT contains 'S' (Subsequent call), then the routine assumes that trigonometric coefficients for the specified value of n are supplied in the array TRIG, having been calculated in a previous call to one of C06FPF, C06FQF or C06FRF.

If INIT contains 'R' (Restart) then the routine assumes that trigonometric coefficients for the particular value of n are supplied in the array TRIG, but does not check that C06FPF,

C06FQF or C06FRF have previously been called. This option allows the TRIG array to be stored in an external file, read in and re-used without the need for a call with INIT equal to 'I'. The routine carries out a simple test to check that the current value of n is compatible with the array TRIG. Constraint: INIT = 'I', 'S' or 'R'.

6: TRIG(2\*N) -- DOUBLE PRECISION array Input/Output  
 On entry: if INIT = 'S' or 'R', TRIG must contain the required coefficients calculated in a previous call of the routine. Otherwise TRIG need not be set. On exit: TRIG contains the required coefficients (computed by the routine if INIT = 'I').

7: WORK(2\*M\*N) -- DOUBLE PRECISION array Workspace

8: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry M < 1.

IFAIL= 2

On entry N < 1.

IFAIL= 3

On entry INIT is not one of 'I', 'S' or 'R'.

IFAIL= 4

On entry INIT = 'S', but none of C06FPF, C06FQF and C06FRF has previously been called.

IFAIL= 5

On entry INIT = 'S' or 'R', but the array TRIG and the

current value of n are inconsistent.

## 7. Accuracy

Some indication of accuracy can be obtained by performing a subsequent inverse transform and comparing the results with the original sequence (in exact arithmetic they would be identical).

## 8. Further Comments

The time taken by the routine is approximately proportional to  $\text{nm} \cdot \log n$ , but also depends on the factors of  $n$ . The routine is fastest if the only prime factors of  $n$  are 2, 3 and 5, and is particularly slow if  $n$  is a large prime, or has large prime factors.

## 9. Example

This program reads in sequences of complex data values and prints their discrete Fourier transforms (as computed by C06FRF). Inverse transforms are then calculated using C06GCF and C06FRF and printed out, showing that the original sequences are restored.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

C06FUF(3NAG)      Foundation Library (12/10/92)      C06FUF(3NAG)

C06 -- Summation of Series C06FUF

C06FUF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

C06FUF computes the two-dimensional discrete Fourier transform of a bivariate sequence of complex data values. This routine is designed to be particularly efficient on vector processors.

## 2. Specification

```

SUBROUTINE C06FUF (M, N, X, Y, INIT, TRIGM, TRIGN, WORK,
1 IFAIL)
 INTEGER M, N, IFAIL
 DOUBLE PRECISION X(M*N), Y(M*N), TRIGM(2*M), TRIGN(2*N),
1 WORK(2*M*N)
 CHARACTER*1 INIT

```

## 3. Description

This routine computes the two-dimensional discrete Fourier transform of a bivariate sequence of complex data values  $z_{j_1 j_2}$ ,

where  $j_1 = 0, 1, \dots, m-1$ ,  $j_2 = 0, 1, \dots, n-1$ .

The discrete Fourier transform is here defined by:

$$z_{k_1 k_2} = \frac{1}{\sqrt{mn}} \sum_{j_1=0}^{m-1} \sum_{j_2=0}^{n-1} z_{j_1 j_2} \exp(-2(\pi)i \left( \frac{j_1 k_1}{m} + \frac{j_2 k_2}{n} \right)),$$

where  $k_1 = 0, 1, \dots, m-1$ ,  $k_2 = 0, 1, \dots, n-1$ .

(Note the scale factor of  $\frac{1}{\sqrt{mn}}$  in this definition.)

$\sqrt{mn}$

To compute the inverse discrete Fourier transform, defined with  $\exp(+2(\pi)i(\dots))$  in the above formula instead of  $\exp(-2(\pi)i(\dots))$ , this routine should be preceded and followed by calls of C06GCF to form the complex conjugates of the data values and the transform.

This routine calls C06FRF to perform multiple one-dimensional discrete Fourier transforms by the fast Fourier transform (FFT) algorithm in Brigham [1]. It is designed to be particularly efficient on vector processors.

## 5. Parameters

1: M -- INTEGER Input  
 On entry: the number of rows, m, of the arrays X and Y.  
 Constraint: M >= 1.

2: N -- INTEGER Input  
 On entry: the number of columns, n, of the arrays X and Y.  
 Constraint: N >= 1.

3: X(M,N) -- DOUBLE PRECISION array Input/Output

4: Y(M,N) -- DOUBLE PRECISION array Input/Output  
 On entry: the real and imaginary parts of the complex data values must be stored in arrays X and Y respectively. If X and Y are regarded as two-dimensional arrays of dimension (0:M-1,0:N-1), then  $X(j_1, j_2)$  and  $Y(j_1, j_2)$  must contain the real and imaginary parts of  $z_{j_1 j_2}$ . On exit: the real and imaginary parts respectively of the corresponding elements of the computed transform.

5: INIT -- CHARACTER\*1 Input  
 On entry: if the trigonometric coefficients required to compute the transforms are to be calculated by the routine and stored in the arrays TRIGM and TRIGN, then INIT must be set equal to 'I', (Initial call).

If INIT contains 'S', (Subsequent call), then the routine assumes that trigonometric coefficients for the specified values of m and n are supplied in the arrays TRIGM and TRIGN, having been calculated in a previous call to the routine.

If INIT contains 'R', (Restart), then the routine assumes

that trigonometric coefficients for the particular values of  $m$  and  $n$  are supplied in the arrays TRIGM and TRIGN, but does not check that the routine has previously been called. This option allows the TRIGM and TRIGN arrays to be stored in an external file, read in and re-used without the need for a call with INIT equal to 'I'. The routine carries out a simple test to check that the current values of  $m$  and  $n$  are compatible with the arrays TRIGM and TRIGN. Constraint: INIT = 'I', 'S' or 'R'.

- 6: TRIGM(2\*M) -- DOUBLE PRECISION array                      Input/Output
- 7: TRIGN(2\*N) -- DOUBLE PRECISION array                      Input/Output  
 On entry: if INIT = 'S' or 'R', TRIGM and TRIGN must contain the required coefficients calculated in a previous call of the routine. Otherwise TRIGM and TRIGN need not be set.

If  $m=n$  the same array may be supplied for TRIGM and TRIGN.  
 On exit: TRIGM and TRIGN contain the required coefficients (computed by the routine if INIT = 'I').

- 8: WORK(2\*M\*N) -- DOUBLE PRECISION array                      Workspace
- 9: IFAIL -- INTEGER                                              Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry  $M < 1$ .

IFAIL= 2

On entry  $N < 1$ .

IFAIL= 3

On entry INIT is not one of 'I', 'S' or 'R'.

On entry INIT = 'S', but C06FUF has not previously been called.

On entry INIT = 'S' or 'R', but at least one of the arrays TRIGM and TRIGN is inconsistent with the current value of M or N.

Some indication of accuracy can be obtained by performing a subsequent inverse transform and comparing the results with the original sequence (in exact arithmetic they would be identical).

The time taken by the routine is approximately proportional to  $mn \cdot \log(mn)$ , but also depends on the factorization of the individual dimensions  $m$  and  $n$ . The routine is somewhat faster than average if their only prime factors are 2, 3 or 5; and fastest of all if they are powers of 2.

This program reads in a bivariate sequence of complex data values and prints the two-dimensional Fourier transform. It then performs an inverse transform and prints the sequence so obtained, which may be compared to the original data values.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

C06GBF(3NAG)      Foundation Library (12/10/92)      C06GBF(3NAG)

C06 -- Summation of Series C06GBF  
C06GBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

C06GBF forms the complex conjugate of a Hermitian sequence of  $n$  data values.

## 2. Specification

```

SUBROUTINE C06GBF (X, N, IFAIL)
 INTEGER N, IFAIL
 DOUBLE PRECISION X(N)

```

## 3. Description

This is a utility routine for use in conjunction with C06EAF, C06EBF, C06FAF(\*) or C06FBF(\*) to calculate inverse discrete Fourier transforms (see the Chapter Introduction).

## 4. References

None.

## 5. Parameters

- 1: X(N) -- DOUBLE PRECISION array Input/Output  
 On entry: if the data values  $z_j$  are written as  $x_j + iy_j$  and if X is declared with bounds (0:N-1) in the (sub)program from which C06GBF is called, then for  $0 \leq j \leq n/2$ , X(j) must contain  $x_j (=x_{n-j})$ , while for  $n/2 < j \leq n-1$ , X(j) must contain  $-y_j (=y_{n-j})$ . In other words, X must contain the Hermitian sequence in Hermitian form. (See also Section 2.1.2 of the Chapter Introduction). On exit: the imaginary parts  $y_j$  are negated. The real parts  $x_j$  are not referenced.
- 2: N -- INTEGER Input  
 On entry: the number of data values,  $n$ . Constraint:  $N \geq 1$ .
- 3: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
N < 1.

## 7. Accuracy

Exact.

## 8. Further Comments

The time taken by the routine is negligible.

## 9. Example

This program reads in a sequence of real data values, calls C06EAF followed by C06GBF to compute their inverse discrete Fourier transform, and prints this after expanding it from Hermitian form into a full complex sequence.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

[illegible]

C06 -- Summation of Series C06GCF  
C06GCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

C06GCF forms the complex conjugate of a sequence of n data values.

## 2. Specification

```

SUBROUTINE C06GCF (Y, N, IFAIL)
 INTEGER N, IFAIL
 DOUBLE PRECISION Y(N)

```

## 3. Description

This is a utility routine for use in conjunction with C06ECF or C06FCF(\*) to calculate inverse discrete Fourier transforms (see the Chapter Introduction).

## 4. References

None.

## 5. Parameters

- 1: Y(N) -- DOUBLE PRECISION array Input/Output  
 On entry: if Y is declared with bounds (0:N-1) in the (sub) program which C06GCF is called, then Y(j) must contain the imaginary part of the jth data value, for  $0 \leq j \leq n-1$ . On exit: these values are negated.
- 2: N -- INTEGER Input  
 On entry: the number of data values, n. Constraint:  $N \geq 1$ .
- 3: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

```

IFAIL= 1
 N < 1.

```

## 7. Accuracy

Exact.

## 8. Further Comments

The time taken by the routine is negligible.

## 9. Example

This program reads in a sequence of complex data values and prints their inverse discrete Fourier transform as computed by calling C06GCF, followed by C06ECF and C06GCF again.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

C06GQF(3NAG)      Foundation Library (12/10/92)      C06GQF(3NAG)

C06 -- Summation of Series C06GQF  
C06GQF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

C06GQF forms the complex conjugates of m Hermitian sequences, each containing n data values.

## 2. Specification

```

SUBROUTINE C06GQF (M, N, X, IFAIL)
 INTEGER M, N, IFAIL
 DOUBLE PRECISION X(M*N)

```

### 3. Description

This is a utility routine for use in conjunction with C06FPF and C06FQF to calculate inverse discrete Fourier transforms (see the Chapter Introduction).

## 4. References

None.

## 5. Parameters

- 1: M -- INTEGER Input  
On entry: the number of Hermitian sequences to be conjugated, m. Constraint:  $M \geq 1$ .
- 2: N -- INTEGER Input  
On entry: the number of data values in each Hermitian sequence, n. Constraint:  $N \geq 1$ .
- 3: X(M,N) -- DOUBLE PRECISION array Input/Output  
On entry: the data must be stored in array X as if in a two-dimensional array of dimension (1:M,0:N-1); each of the m sequences is stored in a row of the array in Hermitian form. If the n data values  $z_{j,p}$  are written as  $x_{j,p} + iy_{j,p}$ , then for  $0 \leq j \leq n/2$ ,  $x_{j,p}$  is contained in  $X(p,j)$ , and for  $1 \leq j \leq (n-1)/2$ ,  $y_{j,p}$  is contained in  $X(p,n-j)$ . (See also Section 2.1.2 of the Chapter Introduction.) On exit: the imaginary parts  $y_{j,p}$  are negated. The real parts  $x_{j,p}$  are not referenced.
- 4: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

IFAIL= 2

## 7. Accuracy

Exact.

## 8. Further Comments

None.

## 9. Example

This program reads in sequences of real data values which are assumed to be Hermitian sequences of complex data stored in Hermitian form. The sequences are expanded into full complex form using C06GSF and printed. The sequences are then conjugated (using C06GQF) and the conjugated sequences are expanded into complex form using C06GSF and printed out.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

C06GSF takes m Hermitian sequences, each containing n data values, and forms the real and imaginary parts of the m corresponding complex sequences.

## 2. Specification

```

SUBROUTINE C06GSF (M, N, X, U, V, IFAIL)
 INTEGER M, N, IFAIL
 DOUBLE PRECISION X(M*N), U(M*N), V(M*N)

```

### 3. Description

This is a utility routine for use in conjunction with C06FPF and C06FQF (see the Chapter Introduction).

### 4. References

None.

### 5. Parameters

- 1: M -- INTEGER Input  
On entry: the number of Hermitian sequences, m, to be converted into complex form. Constraint: M ≥ 1.
- 2: N -- INTEGER Input  
On entry: the number of data values, n, in each sequence. Constraint: N ≥ 1.
- 3: X(M,N) -- DOUBLE PRECISION array Input  
On entry: the data must be stored in X as if in a two-dimensional array of dimension (1:M,0:N-1); each of the m sequences is stored in a row of the array in Hermitian form.  
If the n data values  $z_j^p$  are written as  $x_j^p + iy_j^p$ , then for  $0 \leq j \leq n/2$ ,  $x_j^p$  is contained in X(p,j), and for  $1 \leq j \leq (n-1)/2$ ,  $y_j^p$  is contained in X(p,n-j). (See also Section 2.1.2 of the Chapter Introduction.)
- 4: U(M,N) -- DOUBLE PRECISION array Output
- 5: V(M,N) -- DOUBLE PRECISION array Output  
On exit: the real and imaginary parts of the m sequences of length n, are stored in U and V respectively, as if in two-dimensional arrays of dimension (1:M,0:N-1); each of the m sequences is stored as if in a row of each array. In other words, if the real parts of the pth sequence are denoted by

$$x_j^p, \text{ for } j=0,1,\dots,n-1 \text{ then the } mn \text{ elements of the array } U_j$$
 contain the values
 
$$\begin{array}{ccccccc}
 1 & 2 & & m & 1 & 2 & & m & & 1 & 2 & & m \\
 x & ,x & ,\dots,x & , & x & ,x & ,\dots,x & ,\dots, & x & ,x & ,\dots,x \\
 0 & 0 & & 0 & 1 & 1 & & 1 & & n-1 & n-1 & & n-1
 \end{array}$$

6: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1  
 On entry M < 1.

IFAIL= 2  
 On entry N < 1.

#### 7. Accuracy

Exact.

#### 8. Further Comments

None.

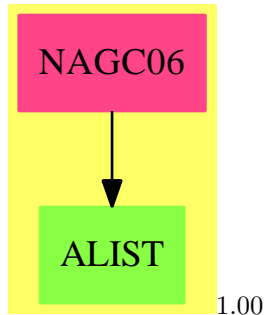

#### 9. Example

This program reads in sequences of real data values which are assumed to be Hermitian sequences of complex data stored in Hermitian form. The sequences are then expanded into full complex form using C06GSF and printed.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation

Library software and should be available on-line.

```
S -- Approximations of Special Functions Introduction -- S
 Chapter S
 Approximations of Special Functions
```

### 1. Scope of the Chapter

This chapter is concerned with the provision of some commonly occurring physical and mathematical functions.

### 2. Background to the Problems

The majority of the routines in this chapter approximate real-valued functions of a single real argument, and the techniques involved are described in Section 2.1. In addition the chapter contains routines for elliptic integrals (see Section 2.2), Bessel and Airy functions of a complex argument (see Section 2.3), and exponential of a complex argument.

#### 2.1. Functions of a Single Real Argument

Most of the routines for functions of a single real argument have been based on truncated Chebyshev expansions. This method of approximation was adopted as a compromise between the conflicting requirements of efficiency and ease of implementation on many different machine ranges. For details of the reasons behind this choice and the production and testing procedures followed in constructing this chapter see Schonfelder [7].

Basically if the function to be approximated is  $f(x)$ , then for  $x$  in  $[a, b]$  an approximation of the form

$$f(x) \approx \sum_{r=0}^T C_r T_r(t)$$

is used, (  $\approx$  ) denotes, according to the usual convention, a

summation in which the first term is halved), where  $g(x)$  is some suitable auxiliary function which extracts any singularities, asymptotes and, if possible, zeros of the function in the range in question and  $t=t(x)$  is a mapping of the general range  $[a,b]$  to the specific range  $[-1,+1]$  required by the Chebyshev polynomials,  $T(t)$ . For a detailed description of the properties of the

$r$   
Chebyshev polynomials see Clenshaw [5] and Fox and Parker [6].

The essential property of these polynomials for the purposes of function approximation is that  $T(t)$  oscillates between  $\pm 1$  and

$n$   
it takes its extreme values  $n+1$  times in the interval  $[-1,+1]$ . Therefore, provided the coefficients  $C$  decrease in magnitude

$r$   
sufficiently rapidly the error made by truncating the Chebyshev expansion after  $n$  terms is approximately given by

$$E(t) \sim C_n T(t)$$

That is the error oscillates between  $\pm C_n$  and takes its extreme

$n$   
value  $n+1$  times in the interval in question. Now this is just the condition that the approximation be a mini-max representation, one which minimizes the maximum error. By suitable choice of the interval,  $[a,b]$ , the auxiliary function,  $g(x)$ , and the mapping of the independent variable,  $t(x)$ , it is almost always possible to obtain a Chebyshev expansion with rapid convergence and hence truncations that provide near mini-max polynomial approximations to the required function. The difference between the true mini-max polynomial and the truncated Chebyshev expansion is seldom sufficiently great to be of significance.

The evaluation of the Chebyshev expansions follows one of two methods. The first and most efficient, and hence most commonly used, works with the equivalent simple polynomial. The second method, which is used on the few occasions when the first method proves to be unstable, is based directly on the truncated Chebyshev series and uses backward recursion to evaluate the sum. For the first method, a suitably truncated Chebyshev expansion (truncation is chosen so that the error is less than the machine precision) is converted to the equivalent simple polynomial. That is we evaluate the set of coefficients  $b$  such that

$r$

$$y(t) = \sum_{r=0}^{n-1} b_r t^r = \sum_{r=0}^{n-1} C_r T_r(t).$$

The polynomial can then be evaluated by the efficient Horner's method of nested multiplications,

$$y(t) = (b_0 + t(b_1 + t(b_2 + \dots t(b_{n-2} + tb_{n-1}))))).$$

This method of evaluation results in efficient routines but for some expansions there is considerable loss of accuracy due to cancellation effects. In these cases the second method is used. It is well known that if

$$\begin{aligned} b_{n-1} &= C \\ b_{n-2} &= 2tb_{n-1} + C \\ b_j &= 2tb_{j+1} - b_{j+2} + C, \quad j = n-3, n-4, \dots, 0 \end{aligned}$$

then

$$\sum_{r=0}^{n-1} C_r T_r(t) = -(b_0 - b_2)$$

and this is always stable. This method is most efficiently implemented by using three variables cyclically and explicitly constructing the recursion.

That is,

$$\begin{aligned} (\alpha) &= C \\ (\beta) &= 2t(\alpha) + C \\ (\gamma) &= 2t(\beta) - (\alpha) + C \end{aligned}$$

$$\begin{aligned}
 (\alpha) &= 2t(\gamma) - (\beta) + C \\
 (\beta) &= 2t(\alpha) - (\gamma) + C \\
 &\dots \\
 &\dots \\
 (\alpha) &= 2t(\gamma) - (\beta) + C \quad (\text{say}) \\
 (\beta) &= 2t(\alpha) - (\gamma) + C \\
 y(t) &= t(\beta) - (\alpha) + \dots
 \end{aligned}$$

The auxiliary functions used are normally functions compounded of simple polynomial (usually linear) factors extracting zeros, and the primary compiler-provided functions, sin, cos, ln, exp, sqrt, which extract singularities and/or asymptotes or in some cases basic oscillatory behaviour, leaving a smooth well-behaved function to be approximated by the Chebyshev expansion which can therefore be rapidly convergent.

The mappings of  $[a, b]$  to  $[-1, +1]$  used, range from simple linear mappings to the case when  $b$  is infinite and considerable improvement in convergence can be obtained by use of a bilinear form of mapping. Another common form of mapping is used when the function is even, that is it involves only even powers in its expansion. In this case an approximation over the whole interval  $[-a, a]$  can be provided using a mapping  $t = 2(-) - 1$ . This embodies the evenness property but the expansion in  $t$  involves all powers and hence removes the necessity of working with an expansion with half its coefficients zero.

For many of the routines an analysis of the error in principle is given, viz, if  $E$  and  $(\text{nabla})$  are the absolute errors in function and argument and  $(\text{epsilon})$  and  $(\text{delta})$  are the corresponding relative errors, then

$$\begin{aligned}
 E &\sim |f'(x)| (\text{nabla}) \\
 E &\sim |xf'(x)| (\text{delta}) \\
 (\text{epsilon}) &\sim \frac{|xf'(x)|}{\dots} (\text{delta})
 \end{aligned}$$

$$|f(x)|$$

If we ignore errors that arise in the argument of the function by propagation of data errors etc and consider only those errors that result from the fact that a real number is being represented in the computer in floating-point form with finite precision, then  $(\delta)$  is bounded and this bound is independent of the magnitude of  $x$ ; e.g. on an 11-digit machine

$$|(\delta)| \leq 10^{-11}.$$

(This of course implies that the absolute error  $(\delta) = x(\delta)$  is also bounded but the bound is now dependent on  $x$ ). However because of this the last two relations above are probably of more interest. If possible the relative error propagation is discussed; that is the behaviour of the error amplification factor  $|xf'(x)/f(x)|$  is described, but in some cases, such as near zeros of the function which cannot be extracted explicitly, absolute error in the result is the quantity of significance and here the factor  $|xf'(x)|$  is described. In general, testing of the functions has shown that their error behaviour follows fairly well these theoretical error behaviours. In regions, where the error amplification factors are less than or of the order of one, the errors are slightly larger than the above predictions. The errors are here limited largely by the finite precision of arithmetic in the machine but  $(\epsilon)$  is normally no more than a few times greater than the bound on  $(\delta)$ . In regions where the amplification factors are large, order of ten or greater, the theoretical analysis gives a good measure of the accuracy obtainable.

It should be noted that the definitions and notations used for the functions in this chapter are all taken from Abramowitz and Stegun [1]. Users are strongly recommended to consult this book for details before using the routines in this chapter.

## 2.2. Approximations to Elliptic Integrals

The functions provided here are symmetrised variants of the classic elliptic integrals. These alternative definitions have been suggested by Carlson (see [2], [3] and [4]) and he also developed the basic algorithms used in this chapter.

The standard integral of the first kind is represented by

$$R_{\text{F}}(x,y,z) = - \frac{1}{2} \int_0^{\infty} \frac{dt}{\sqrt{(t+x)(t+y)(t+z)}}$$

where  $x,y,z \geq 0$  and at most one may be equal to zero.

The normalisation factor,  $-\frac{1}{2}$ , is chosen so as to make

$$R_{\text{F}}(x,x,x) = 1/\sqrt{x}.$$

If any two of the variables are equal,  $R_{\text{F}}$  degenerates into the second function

$$R_{\text{C}}(x,y) = R_{\text{F}}(x,y,y) = - \frac{1}{2} \int_0^{\infty} \frac{dt}{\sqrt{t+x(t+y)}}$$

where the argument restrictions are now  $x \geq 0$  and  $y \neq 0$ .

This function is related to the logarithm or inverse hyperbolic functions if  $0 < y < x$ , and to the inverse circular functions if  $0 \leq x \leq y$ .

The integrals of the second kind are defined by

$$R_{\text{D}}(x,y,z) = - \frac{3}{2} \int_0^{\infty} \frac{dt}{\sqrt{(t+x)(t+y)(t+z)^3}}$$

with  $z > 0$ ,  $x \geq 0$  and  $y \geq 0$  but only one of  $x$  or  $y$  may be zero.

The function is a degenerate special case of the integral of the third kind

$$R_J(x, y, z, (\rho)) = - \frac{3}{2} \int_0^{\infty} \frac{dt}{(\sqrt{(t+x)(t+y)(t+z)})(t+(\rho))}$$

with  $(\rho) \neq 0$ ,  $x, y, z \geq 0$  with at most one equality holding. Thus  $R(x, y, z) = R(x, y, z, z)$ . The normalisation of both these functions is chosen so that

$$R_D(x, x, x) = R_J(x, x, x, x) = 1/(\sqrt{x})$$

The algorithms used for all these functions are based on duplication theorems. These allow a recursion system to be established which constructs a new set of arguments from the old using a combination of arithmetic and geometric means. The value of the function at the original arguments can then be simply related to the value at the new arguments. These recursive reductions are used until the arguments differ from the mean by an amount small enough for a Taylor series about the mean to give sufficient accuracy when retaining terms of order less than six. Each step of the recurrences reduces the difference from the mean by a factor of four, and as the truncation error is of order six, the truncation error goes like  $(4/9)^n$ , where  $n$  is the number of iterations.

The above forms can be related to the more traditional canonical forms (see Abramowitz and Stegun [1], 17.2).

If we write  $q = \cos^2(\phi)$ ,  $r = 1 - m \sin^2(\phi)$ ,  $s = 1 + n \sin^2(\phi)$ , where  $0 < \phi \leq \frac{1}{2}\pi$ , we have: the elliptic integral of the first kind:

$$\frac{\sin(\phi)}{\sqrt{1 - m \sin^2(\phi) (1 + n \sin^2(\phi))}}$$

$$F(\phi|m) = \frac{\int_0^1 (1-t)^{-1/2} (1-mt)^{-1/2} dt \sin(\phi).R(q,r,1)}{F}$$

the elliptic integral of the second kind:

$$E(\phi|m) = \frac{\int_0^1 (1-t)^{-1/2} (1-mt)^{-1/2} dt \sin(\phi)}{F} = \sin(\phi).R(q,r,1) - \frac{1}{3} m \sin^3(\phi).R(q,r,1)$$

the elliptic integral of the third kind:

$$(Pi)(n;\phi|m) = \frac{\int_0^1 (1-t)^{-1/2} (1-mt)^{-1/2} (1+nt)^{-1} dt \sin(\phi)}{F} = \sin(\phi).R(q,r,1) - \frac{1}{3} n \sin^3(\phi).R(q,r,1,s)$$

Also the complete elliptic integral of the first kind:

$$K(m) = \frac{\int_0^{\pi/2} (1-m \sin^2(\theta))^{-1/2} d(\theta)}{F} = R(0,1-m,1);$$

the complete elliptic integral of the second kind:

$$E(m) = \frac{\int_0^{\pi/2} (1-m \sin^2(\theta))^{1/2} d(\theta)}{F} = R(0,1-m,1) - \frac{1}{3} m R(0,1-m,1).$$

### 2.3. Bessel and Airy Functions of a Complex Argument

The routines for Bessel and Airy functions of a real argument are based on Chebyshev expansions, as described in Section 2.1. The routines for functions of a complex argument, however, use different methods. These routines relate all functions to the modified Bessel functions  $I_{\nu}(z)$  and  $K_{\nu}(z)$  computed in the right-half complex plane, including their analytic continuations.  $I_{\nu}$  and  $K_{\nu}$  are computed by different methods according to the values of  $z$  and  $\nu$ . The methods include power series, asymptotic expansions and Wronskian evaluations. The relations between functions are based on well known formulae (see Abramowitz and Stegun [1]).

### 3. Recommendations on Choice and Use of Routines

#### 3.1. Elliptic Integrals

IMPORTANT ADVICE: users who encounter elliptic integrals in the course of their work are strongly recommended to look at transforming their analysis directly to one of the Carlson forms, rather than the traditional canonical Legendre forms. In general,

the extra symmetry of the Carlson forms is likely to simplify the analysis, and these symmetric forms are much more stable to calculate.

The routine S21BAF for R is largely included as an auxiliary to C the other routines for elliptic integrals. This integral essentially calculates elementary functions, e.g.

$$\ln x = (x-1) \cdot R \left( \frac{(1+x)^2}{C(2)}, x \right), x > 0;$$

$$\arcsin x = x \cdot R \left( \frac{1-x^2}{C}, 1 \right), |x| \leq 1;$$

$$\operatorname{arcsinh} x = x \cdot R \left( \frac{1+x^2}{C}, 1 \right), \text{ etc}$$

In general this method of calculating these elementary functions is not recommended as there are usually much more efficient specific routines available in the Library. However, S21BAF may be used, for example, to compute  $\ln x/(x-1)$  when  $x$  is close to 1, without the loss of significant figures that occurs when  $\ln x$  and  $x-1$  are computed separately.

### 3.2. Bessel and Airy Functions

For computing the Bessel functions  $J_{(\nu)}(x)$ ,  $Y_{(\nu)}(x)$ ,  $I_{(\nu)}(x)$  and  $K_{(\nu)}(x)$  where  $x$  is real and  $(\nu)=0$  or 1, special routines are provided, which are much faster than the more general routines that allow a complex argument and arbitrary real  $(\nu) \geq 0$  functions and their derivatives  $Ai(x)$ ,  $Bi(x)$ ,  $Ai'(x)$ ,  $Bi'(x)$  for a real argument which are much faster than the routines for complex arguments.

S01 -- Approximations of Special Functions
S01EAF -- NAG Foundation Library Routine Document

```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

S01EAF evaluates the exponential function  $e^z$ , for complex  $z$ .

## 2. Specification

```

COMPLEX(KIND(1.0D0)) FUNCTION S01EAF (Z, IFAIL)
INTEGER IFAIL
COMPLEX(KIND(1.0D0)) Z

```

## 3. Description

This routine evaluates the exponential function  $e^z$ , taking care to avoid machine overflow, and giving a warning if the result cannot be computed to more than half precision. The function is evaluated as  $e^z = e^{x+iy} = e^x (\cos y + i \sin y)$ , where  $x$  and  $y$  are the real and imaginary parts respectively of  $z$ .

Since  $\cos y$  and  $\sin y$  are less than or equal to 1 in magnitude, it is possible that  $e^x$  may overflow although  $e^x \cos y$  or  $e^x \sin y$  does not. In this case the alternative formula  $\text{sign}(\cos y)e^{x+\ln|\cos y|}$  is used for the real part of the result, and  $\text{sign}(\sin y)e^{x+\ln|\sin y|}$  for the imaginary part. If either part of the result still overflows, a warning is returned through parameter IFAIL.

If  $\text{Im } z$  is too large, precision may be lost in the evaluation of  $\sin y$  and  $\cos y$ . Again, a warning is returned through IFAIL.

## 4. References

None.

## 5. Parameters

- 1: Z -- COMPLEX(KIND(1.0D0)) Input  
On entry: the argument  $z$  of the function.
- 2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not

familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

The real part of the result overflows, and is set to the largest safe number with the correct sign. The imaginary part of the result is meaningful.

IFAIL= 2

The imaginary part of the result overflows, and is set to the largest safe number with the correct sign. The real part of the result is meaningful.

IFAIL= 3

Both real and imaginary parts of the result overflow, and are set to the largest safe number with the correct signs.

IFAIL= 4

The computed result is accurate to less than half precision, due to the size of  $\text{Im } z$ .

IFAIL= 5

The computed result has no precision, due to the size of  $\text{Im } z$ , and is set to zero.

## 7. Accuracy

Accuracy is limited in general only by the accuracy of the Fortran intrinsic functions in the computation of  $\sin y$ ,  $\cos y$  and  $e^x$

, where  $x = \text{Re } z$ ,  $y = \text{Im } z$ . As  $y$  gets larger, precision will probably be lost due to argument reduction in the evaluation of the sine and cosine functions, until the warning error IFAIL = 4

occurs when  $y$  gets larger than  $\sqrt{1/(\text{epsilon})}$ , where (epsilon) is the machine precision. Note that on some machines, the intrinsic functions SIN and COS will not operate on arguments larger than

about  $\sqrt{1/(\epsilon)}$ , and so IFAIL can never return as 4.

In the comparatively rare event that the result is computed by  

$$\frac{x + \ln|\cos y|}{x + \ln|\sin y|}$$
the formulae  $\text{sign}(\cos y)e$  and  $\text{sign}(\sin y)e$ , a  
further small loss of accuracy may be expected due to rounding  
errors in the logarithmic function.

#### 8. Further Comments

None.

#### 9. Example

The example program reads values of the argument  $z$  from a file,  
evaluates the function at each value of  $z$  and prints the results.

The example program is not reproduced here. The source code for  
all example programs is distributed with the NAG Foundation  
Library software and should be available on-line.

S13 -- Approximations of Special Functions S13AAF  
S13AAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for  
your implementation to check implementation-dependent details.  
The symbol (\*) after a NAG routine name denotes a routine that is  
not included in the Foundation Library.

#### 1. Purpose

S13AAF returns the value of the exponential integral  $E(x)$ , via  
1  
the routine name.

#### 2. Specification

```
DOUBLE PRECISION FUNCTION S13AAF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

#### 3. Description

The routine calculates an approximate value for

$$E(x) = \frac{1}{x} \int_0^{\infty} \frac{e^{-u}}{u} du, \quad x > 0.$$

For  $0 < x \leq 4$ , the approximation is based on the Chebyshev expansion

$$E(x) = y(t) - \ln x = \sum_{r=0}^{\infty} a_r T_r(t) - \ln x, \quad \text{where } t = \frac{-x-1}{2}.$$

For  $x > 4$ ,

$$E(x) = \frac{e^{-x}}{x} y(t) = \frac{e^{-x}}{x} \sum_{r=0}^{\infty} a_r T_r(t),$$

$$\text{where } t = -1.0 + 14.5/(x+3.25) = \frac{11.25-x}{3.25+x}.$$

In both cases,  $-1 \leq t \leq +1$ .

To guard against producing underflows, if  $x > x_{hi}$  the result is set directly to zero. For the value  $x_{hi}$  see the Users' Note for your implementation.

#### 4. References

- [1] Abramowitz M and Stegun I A (1965) Handbook of Mathematical Functions. Dover Publications. Ch. 26.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument x of the function. Constraint: X > 0.  
 0.

2: IFAIL -- INTEGER Input/Output  
 Before entry, IFAIL must be assigned a value. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

Unless the routine detects an error (see Section 6), IFAIL contains 0 on exit.

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

The routine has been called with an argument less than or equal to zero for which the function is not defined. The result returned is zero.

## 7. Accuracy

If (delta) and (epsilon) are the relative errors in argument and result respectively, then in principle,

$$|(\text{epsilon})| \sim \frac{e^{-x}}{E(x)} |(\text{delta})|$$

so the relative error in the argument is amplified in the result by at least a factor  $e^{-x}$ .

The equality should hold if

(delta) is greater than the machine precision ((delta) due to data errors etc) but if (delta) is simply a result of round-off in the machine representation, it is possible that an extra figure may be lost in internal calculation and round-off.

The behaviour of this amplification factor is shown in Figure 1.

Figure 1

Please see figure in printed Reference Manual

It should be noted that, for small x, the amplification factor tends to zero and eventually the error in the result will be limited by machine precision.

For large  $x$ ,

$$(\epsilon)^x (\delta) = (\Delta),$$

the absolute error in the argument.

#### 8. Further Comments

None.

#### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S13 -- Approximations of Special Functions

S13ACF

S13ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S13ACF returns the value of the cosine integral

$$Ci(x) = (\gamma) + \ln x + \int_0^x \frac{\cos u - 1}{u} du, \quad x > 0$$

via the routine name, where  $(\gamma)$  denotes Euler's constant.

#### 2. Specification

DOUBLE PRECISION FUNCTION S13ACF (X, IFAIL)

INTEGER IFAIL

## DOUBLE PRECISION X

## 3. Description

The routine calculates an approximate value for  $Ci(x)$ .

For  $0 < x \leq 16$  it is based on the Chebyshev expansion

$$Ci(x) = \ln x + \sum_{r=0}^{16} a_r T_r\left(\frac{x}{16}\right), \quad t = 2\left(\frac{x}{16}\right) - 1.$$

For  $16 < x < x_{hi}$  where the value of  $x_{hi}$  is given in the Users' Note for your implementation,

$$Ci(x) = \frac{f(x)\sin x}{x} + \frac{g(x)\cos x}{x^2}$$

$$\text{where } f(x) = \sum_{r=0}^{16} f_r T_r\left(\frac{x}{16}\right) \text{ and } g(x) = \sum_{r=0}^{16} g_r T_r\left(\frac{x}{16}\right), \quad t = 2\left(\frac{x}{16}\right) - 1.$$

For  $x \geq x_{hi}$ ,  $Ci(x) = 0$  to within the accuracy possible (see Section 7).

## 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

## 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
On entry: the argument x of the function. Constraint: X > 0.  
0.
- 2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

The routine has been called with an argument less than or equal to zero for which the function is not defined. The result returned is zero.

## 7. Accuracy

If  $E$  and  $(\epsilon)$  are the absolute and relative errors in the result and  $(\delta)$  is the relative error in the argument then in principle these are related by

$$|E| \sim |(\delta)\cos x| \quad \text{and} \quad |(\epsilon)| \sim \frac{|(\delta)\cos x|}{|Ci(x)|}.$$

That is accuracy will be limited by machine precision near the origin and near the zeros of  $\cos x$ , but near the zeros of  $Ci(x)$  only absolute accuracy can be maintained.

The behaviour of this amplification is shown in Figure 1.

Figure 1

Please see figure in printed Reference Manual

For large values of  $x$ ,  $Ci(x) \sim \frac{\sin x}{x}$  therefore

$(\epsilon) \sim (\delta)x \cot x$  and since  $(\delta)$  is limited by the finite precision of the machine it becomes impossible to return results which have any relative accuracy. That is, when  $x \geq 1/(\delta)$  we have that  $|Ci(x)| \leq 1/x \sim E$  and hence is not significantly different from zero.

Hence  $x_{hi}$  is chosen such that for values of  $x \geq x_{hi}$ ,  $Ci(x)$  in principle would have values less than the machine precision and so is essentially zero.

### 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S13 -- Approximations of Special Functions S13ADF  
 S13ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S13ADF returns the value of the sine integral

$$\text{Si}(x) = \int_0^x \frac{\sin u}{u} du,$$

via the routine name.

### 2. Specification

```
DOUBLE PRECISION FUNCTION S13ADF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

### 3. Description

The routine calculates an approximate value for  $\text{Si}(x)$ .

For  $|x| \leq 16.0$  it is based on the Chebyshev expansion

$$\text{Si}(x) = x \sum_{r=0}^{\infty} a_r T_r(t), \quad t = 2 \left( \frac{x}{16} \right)^2 - 1.$$

For  $16 < |x| < x_{hi}$ , where  $x_{hi}$  is an implementation dependent number,

$$\text{Si}(x) = \text{sign}(x) \left\{ \frac{(\pi)}{2} \frac{f(x) \cos x}{x^2} - \frac{g(x) \sin x}{x^2} \right\}$$

$$\text{where } f(x) = \sum_{r=0}^{\infty} f_r T_r(t) \text{ and } g(x) = \sum_{r=0}^{\infty} g_r T_r(t), \quad t = 2 \left( \frac{x}{16} \right)^2 - 1.$$

For  $|x| > x_{hi}$ ,  $\text{Si}(x) = \frac{1}{2} (\pi) \text{sign} x$  to within machine precision.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
On entry: the argument x of the function.
- 2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL

has been included for consistency with other routines in this chapter.

#### 7. Accuracy

If (delta) and (epsilon) are the relative errors in the argument and result, respectively, then in principle

$$\frac{|(\text{epsilon})|}{|\text{Si}(x)|} \approx \frac{|(\text{delta})\sin x|}{| \text{Si}(x) |}.$$

The equality may hold if (delta) is greater than the machine precision ((delta) due to data errors etc) but if (delta) is simply due to round-off in the machine representation, then since the factor relating (delta) to (epsilon) is always less than one, the accuracy will be limited by machine precision.

#### 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

#### 9. Example

The example program reads values of the argument x from a file, evaluates the function at each value of x and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S14 -- Approximations of Special Functions

S14AAF

S14AAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S14AAF returns the value of the Gamma function (Gamma)(x), via the routine name.

## 2. Specification

```

DOUBLE PRECISION FUNCTION S14AAF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X

```

## 3. Description

This routine evaluates an approximation to the Gamma function  $(\text{Gamma})(x)$ . The routine is based on the Chebyshev expansion:

$$(\text{Gamma})(1+u) = \sum_{r=0}^{\infty} a_r T_r(t), \text{ where } 0 \leq u < 1, t = 2u - 1,$$

and uses the property  $(\text{Gamma})(1+x) = x(\text{Gamma})(x)$ . If  $x = N + 1 + u$  where  $N$  is integral and  $0 \leq u < 1$  then it follows that:

$$\begin{aligned}
 \text{for } N > 0 \quad (\text{Gamma})(x) &= (x-1)(x-2)\dots(x-N)(\text{Gamma})(1+u), \\
 \text{for } N = 0 \quad (\text{Gamma})(x) &= (\text{Gamma})(1+u), \\
 \text{for } N < 0 \quad (\text{Gamma})(x) &= \frac{(\text{Gamma})(1+u)}{x(x+1)(x+2)\dots(x-N-1)}.
 \end{aligned}$$

There are four possible failures for this routine:

- (i) if  $x$  is too large, there is a danger of overflow since  $(\text{Gamma})(x)$  could become too large to be represented in the machine;
- (ii) if  $x$  is too large and negative, there is a danger of underflow;
- (iii) if  $x$  is equal to a negative integer,  $(\text{Gamma})(x)$  would overflow since it has poles at such points;
- (iv) if  $x$  is too near zero, there is again the danger of overflow on some machines. For small  $x$ ,  $(\text{Gamma})(x) \sim \frac{1}{x}$ , and on some machines there exists a range of non-zero but small values of  $x$  for which  $1/x$  is larger than the greatest

representable value.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

1: X -- DOUBLE PRECISION Input  
On entry: the argument x of the function. Constraint: X must not be a negative integer.

2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

The argument is too large. On soft failure the routine returns the approximate value of  $(\Gamma)(x)$  at the nearest valid argument.

IFAIL= 2

The argument is too large and negative. On soft failure the routine returns zero.

IFAIL= 3

The argument is too close to zero. On soft failure the routine returns the approximate value of  $(\Gamma)(x)$  at the nearest valid argument.

IFAIL= 4

The argument is a negative integer, at which value  $(\Gamma)(x)$  is infinite. On soft failure the routine returns a large positive value.

#### 7. Accuracy

Let  $(\delta)$  and  $(\epsilon)$  be the relative errors in the argument and the result respectively. If  $(\delta)$  is somewhat larger than the machine precision (i.e., is due to data errors etc), then  $(\epsilon)$  and  $(\delta)$  are approximately related by:

$$(\epsilon) \sim |x(\Psi)(x)|(\delta)$$

(provided  $(\epsilon)$  is also greater than the representation error). Here  $(\Psi)(x)$  is the digamma function  $\frac{(\Gamma)'(x)}{(\Gamma)(x)}$ .

Figure 1 shows the behaviour of the error amplification factor  $|x(\Psi)(x)|$ .

Figure 1  
Please see figure in printed Reference Manual

If  $(\delta)$  is of the same order as machine precision, then rounding errors could make  $(\epsilon)$  slightly larger than the above relation predicts.

There is clearly a severe, but unavoidable, loss of accuracy for arguments close to the poles of  $(\Gamma)(x)$  at negative integers. However relative accuracy is preserved near the pole at  $x=0$  right up to the point of failure arising from the danger of overflow.

Also accuracy will necessarily be lost as  $x$  becomes large since in this region

$$(\epsilon) \sim (\delta)x \ln x.$$

However since  $(\Gamma)(x)$  increases rapidly with  $x$ , the routine must fail due to the danger of overflow before this loss of accuracy is too great. (e.g. for  $x=20$ , the amplification factor  $\sim 60$ .)

#### 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

#### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S14 -- Approximations of Special Functions S14ABF  
 S14ABF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S14ABF returns a value for the logarithm of the Gamma function,  $\ln(\Gamma(x))$ , via the routine name.

### 2. Specification

```
DOUBLE PRECISION FUNCTION S14ABF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

### 3. Description

This routine evaluates an approximation to  $\ln(\Gamma(x))$ . It is based on two Chebyshev expansions.

For  $0 < x \leq x_{\text{small}}$ ,  $\ln(\Gamma(x)) = -\ln x$  to within machine accuracy.

For  $x_{\text{small}} < x \leq 15.0$ , the recursive relation

$(\Gamma(x+1)) = x(\Gamma(x))$  is used to reduce the calculation to one involving  $(\Gamma(1+u))$ ,  $0 \leq u < 1$  which is evaluated as:

$$(\Gamma(1+u)) = \prod_{r=0}^{\infty} \frac{a_r}{t+r}, \quad t=2u-1.$$

Once  $(\Gamma(x))$  has been calculated, the required result is produced by taking the logarithm.

For  $15.0 < x \leq x_{\text{big}}$ ,

$$\ln(\text{Gamma})(x) = \left(x - \frac{1}{2}\right) \ln x - x + \frac{1}{2} \ln 2(\pi) + y(x)/x$$

where  $y(x) = \sum_{r=0}^{\infty} \frac{b_r}{r!} T_r(t)$ ,  $t = 2\left(\frac{1}{x}\right)^{-1}$ .

For  $x_{\text{big}} < x \leq x_{\text{vbig}}$  the term  $y(x)/x$  is negligible and so its calculation is omitted.

For  $x > x_{\text{vbig}}$  there is a danger of setting overflow so the routine must fail.

For  $x \leq 0.0$  the function is not defined and the routine fails.

Note:  $x_{\text{small}}$  is calculated so that if  $x < x_{\text{small}}$ ,  $(\text{Gamma})(x) = 1/x$  to within machine accuracy.  $x_{\text{big}}$  is calculated so that if  $x > x_{\text{big}}$ ,

$$\ln(\text{Gamma})(x) = \left(x - \frac{1}{2}\right) \ln x - x + \frac{1}{2} \ln 2(\pi)$$

to within machine accuracy.  $x_{\text{vbig}}$  is calculated so that

$\ln(\text{Gamma})(x_{\text{vbig}})$  is close to the value returned by X02ALF(\*).

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

1: X -- DOUBLE PRECISION Input  
On entry: the argument  $x$  of the function. Constraint:  $X > 0$ .

0.

2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

X <= 0.0, the function is undefined. On soft failure, the routine returns zero.

IFAIL= 2

X is too large, the function would overflow. On soft failure, the routine returns the value of the function at the largest permissible argument.

## 7. Accuracy

Let  $(\delta)$  and  $(\epsilon)$  be the relative errors in the argument and result respectively, and  $E$  be the absolute error in the result.

If  $(\delta)$  is somewhat larger than the relative machine precision, then

$$E \sim |x * (\Psi)(x)| (\delta) \quad \text{and} \quad (\epsilon) \sim \frac{|x * (\Psi)(x)|}{|\ln(\Gamma)(x)|} (\delta)$$

where  $(\Psi)(x)$  is the digamma function  $\frac{(\Gamma)'(x)}{(\Gamma)(x)}$ . Figure 1 and Figure 2 show the behaviour of these error amplification factors.

Figure 1

Please see figure in printed Reference Manual

Figure 2

Please see figure in printed Reference Manual

These show that relative error can be controlled, since except near  $x=1$  or  $2$  relative error is attenuated by the function or at least is not greatly amplified.

$$\text{For large } x, (\text{epsilon})^{\sim} = \frac{(1 + \frac{1}{\ln x})}{\ln x} (\text{delta}) \text{ and for small } x,$$

$$(\text{epsilon})^{\sim} = \frac{1}{\ln x} (\text{delta}).$$

The function  $\ln(\Gamma(x))$  has zeros at  $x=1$  and  $2$  and hence relative accuracy is not maintainable near those points. However absolute accuracy can still be provided near those zeros as is shown above.

If however,  $(\text{delta})$  is of the order of the machine precision, then rounding errors in the routine's internal arithmetic may result in errors which are slightly larger than those predicted by the equalities. It should be noted that even in areas where strong attenuation of errors is predicted the relative precision is bounded by the effective machine precision.

#### 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

#### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S14 -- Approximations of Special Functions

S14BAF

S14BAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details.

The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S14BAF computes values for the incomplete gamma functions  $P(a,x)$  and  $Q(a,x)$ .

### 2. Specification

```

SUBROUTINE S14BAF (A, X, TOL, P, Q, IFAIL)
 INTEGER IFAIL
 DOUBLE PRECISION A, X, TOL, P, Q

```

### 3. Description

This subroutine evaluates the incomplete gamma functions in the normalised form

$$P(a,x) = \frac{1}{(\Gamma(a))} \int_0^x t^{a-1} e^{-t} dt,$$

$$Q(a,x) = \frac{1}{(\Gamma(a))} \int_x^{\infty} t^{a-1} e^{-t} dt,$$

with  $x \geq 0$  and  $a > 0$ , to a user-specified accuracy. With this normalisation,  $P(a,x) + Q(a,x) = 1$ .

Several methods are used to evaluate the functions depending on the arguments  $a$  and  $x$ , the methods including Taylor expansion for  $P(a,x)$ , Legendre's continued fraction for  $Q(a,x)$ , and power series for  $Q(a,x)$ . When both  $a$  and  $x$  are large, and  $a \sim x$ , the uniform asymptotic expansion of Temme [3] is employed for greater efficiency - specifically, this expansion is used when  $a \geq 20$  and  $0.7a \leq x \leq 1.4a$ .

Once either of  $P$  or  $Q$  is computed, the other is obtained by subtraction from 1. In order to avoid loss of relative precision in this subtraction, the smaller of  $P$  and  $Q$  is computed first.

This routine is derived from subroutine GAM in Gautschi [2].

- [2] Gautschi W (1979) Algorithm 542: Incomplete Gamma Functions. ACM Trans. Math. Softw. 5 482--489.
- [3] Temme N M (1987) On the Computation of the Incomplete Gamma Functions for Large Values of the Parameters. Algorithms for Approximation. (ed J C Mason and M G Cox) Oxford University Press.

#### 5. Parameters

- 1: A -- DOUBLE PRECISION Input  
On entry: the argument a of the functions. Constraint: A > 0.0.
- 2: X -- DOUBLE PRECISION Input  
On entry: the argument x of the functions. Constraint: X >= 0.0.
- 3: TOL -- DOUBLE PRECISION Input  
On entry: the relative accuracy required by the user in the results. If S14BAF is entered with TOL greater than 1.0 or less than machine precision, then the value of machine precision is used instead.
- 4: P -- DOUBLE PRECISION Output
- 5: Q -- DOUBLE PRECISION Output  
On exit: the values of the functions P(a,x) and Q(a,x) respectively.
- 6: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

On entry  $A \leq 0.0$ .

IFAIL= 2

On entry  $X < 0.0$ .

IFAIL= 3

Convergence of the Taylor series or Legendre continued fraction fails within 600 iterations. This error is extremely unlikely to occur; if it does, contact NAG.

#### 7. Accuracy

There are rare occasions when the relative accuracy attained is somewhat less than that specified by parameter TOL. However, the error should never exceed more than one or two decimal places. Note also that there is a limit of 18 decimal places on the achievable accuracy, because constants in the routine are given to this precision.

#### 8. Further Comments

The time taken for a call of S14BAF depends on the precision requested through TOL, and also varies slightly with the input arguments  $a$  and  $x$ .

#### 9. Example

The example program reads values of the argument  $a$  and  $x$  from a file, evaluates the function and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S15 -- Approximations of Special Functions

S15ADF

S15ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is

not included in the Foundation Library.

### 1. Purpose

S15ADF returns the value of the complementary error function, `erfcx`, via the routine name.

### 2. Specification

```
DOUBLE PRECISION FUNCTION S15ADF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

### 3. Description

The routine calculates an approximate value for the complement of the error function

$$\operatorname{erfc} x = \frac{2}{\sqrt{\pi} x} \int_x^{\infty} e^{-u^2} du = 1 - \operatorname{erf} x.$$

For  $x \geq 0$ , it is based on the Chebyshev expansion

$$\operatorname{erfc} x = e^{-x^2} y(x),$$

where  $y(x) = \sum_{r=0}^{\infty} a_r T_r(t)$  and  $t = (x-3.75)/(x+3.75)$ ,  $-1 \leq t \leq +1$ .  
 $r=0$

For  $x \geq x_{hi}$ , where there is a danger of setting underflow, the result is returned as zero.

$$\text{For } x < 0, \operatorname{erfc} x = 2 - e^{-x^2} y(|x|).$$

For  $x < x_{low} < 0$ , the result is returned as 2.0 which is correct to

within machine precision. The values of  $x_{hi}$  and  $x_{low}$  are given in the Users' Note for your implementation.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

1: X -- DOUBLE PRECISION Input  
On entry: the argument x of the function.

2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL has been included for consistency with other routines in this chapter.

#### 7. Accuracy

If (delta) and (epsilon) are relative errors in the argument and result, respectively, then in principle

$$|(\epsilon)| \sim \frac{2|x|}{\sqrt{\pi} \operatorname{erfc} x} (\delta).$$

That is, the relative error in the argument, x, is amplified by a

factor  $\frac{2|x|}{\sqrt{\pi} \operatorname{erfc} x}$  in the result.

$$\sqrt{\pi} \operatorname{erfc} x$$

The behaviour of this factor is shown in Figure 1.

Figure 1

Please see figure in printed Reference Manual

It should be noted that near  $x=0$  this factor behaves as  $\frac{2x}{\sqrt{\pi}}$

and hence the accuracy is largely determined by the machine precision. Also for large negative  $x$ , where the factor is

$\frac{e^{-x}}{\sqrt{\pi}}$ , accuracy is mainly limited by machine precision.

However, for large positive  $x$ , the factor becomes  $\frac{e^{-x}}{\sqrt{\pi}}$  and to an extent relative accuracy is necessarily lost. The absolute accuracy  $E$  is given by

$$E \sim \frac{e^{-x}}{\sqrt{\pi}} (\delta)$$

so absolute accuracy is guaranteed for all  $x$ .

#### 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

#### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S15 -- Approximations of Special Functions S15AEF  
 S15AEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S15AEF returns the value of the error function  $\operatorname{erf} x$ , via the routine name.

### 2. Specification

```
DOUBLE PRECISION FUNCTION S15AEF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

### 3. Description

Evaluates the error function,

$$\operatorname{erf} x = \frac{\int_0^x e^{-t^2} dt}{\sqrt{\pi}}$$

For  $|x| \leq 2$ ,

$$\operatorname{erf} x = x \left[ 1 - \frac{1}{2} a^2 T(t) \right], \text{ where } t = \frac{x}{\sqrt{1 + a^2}}, \quad a = \frac{1}{x}, \quad x \neq 0$$

```

For 2<|x|<xhi ,
{ 2 }
{ -x }
{ e -- }
erf x = signx{1- ----- > 'b T (t)}, where t= ---.
{ r r }
{ |x|\/(pi) r=0 }

```

```

For |x|>=xhi ,
erf x = signx.

```

x<sub>hi</sub> is the value above which erf x=+-1 within machine precision.

Its value is given in the Users' Note for your implementation.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument x of the function.
- 2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL has been included for consistency with other routines in this chapter.

#### 7. Accuracy

On a machine with approximately 11 significant figures the routine agrees with available tables to 10 figures and consistency checking with S15ADF of the relation

```
erf x+erfc x=1.0
```

shows errors in at worst the 11th figure.

#### 8. Further Comments

None.

#### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

```
%%%
```

```
S17 -- Approximations of Special Functions S17ACF
 S17ACF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S17ACF returns the value of the Bessel Function  $Y(x)$ , via the  
 0  
 routine name.

#### 2. Specification

```
DOUBLE PRECISION FUNCTION S17ACF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

#### 3. Description

This routine evaluates an approximation to the Bessel Function of the second kind  $Y(x)$ .

0

Note:  $Y(x)$  is undefined for  $x \leq 0$  and the routine will fail for such arguments.

The routine is based on four Chebyshev expansions:

For  $0 < x \leq 8$ ,

$$Y(x) = \frac{2}{(\pi)} \ln x + \sum_{r=0}^{\infty} a_r T_r(t) + \sum_{r=0}^{\infty} b_r T_r(t), \text{ with } t = 2\left(\frac{x}{8}\right) - 1,$$

For  $x > 8$ ,

$$Y(x) = \frac{1}{\sqrt{(\pi)x}} \left\{ \sum_{r=0}^{\infty} P_r(x) \sin\left(x - \frac{r\pi}{4}\right) + Q_r(x) \cos\left(x - \frac{r\pi}{4}\right) \right\}$$

$$\text{where } P_r(x) = \sum_{r=0}^{\infty} c_r T_r(t),$$

$$\text{and } Q_r(x) = \sum_{r=0}^{\infty} d_r T_r(t), \text{ with } t = 2\left(\frac{x}{8}\right) - 1.$$

$$\text{For } x \text{ near zero, } Y(x) \sim \frac{2}{(\pi)} \left( \ln\left(\frac{x}{2}\right) + (\gamma) \right), \text{ where } (\gamma)$$

denotes Euler's constant. This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision.

For very large  $x$ , it becomes impossible to provide results with any reasonable accuracy (see Section 7), hence the routine fails. Such arguments contain insufficient information to determine the

phase of oscillation of  $Y(x)$ ; only the amplitude,  $\frac{1}{\sqrt{x}}$ , can be

determined and this is returned on soft failure. The range for which this occurs is roughly related to the machine precision: the routine will fail if  $x > 1/\text{machine precision}$  (see the Users' Note for your implementation for details).

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.
- [2] Clenshaw C W (1962) Mathematical Tables. Chebyshev Series for Mathematical Functions. HMSO.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
On entry: the argument x of the function. Constraint:  $X > 0$ .  
0.
- 2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

X is too large. On soft failure the routine returns the amplitude of the Y oscillation,  $\sqrt{2}/(\pi)x$ .  
0

IFAIL= 2

$X \leq 0.0$ , Y is undefined. On soft failure the routine  
0  
returns zero.

#### 7. Accuracy

Let  $(\delta)$  be the relative error in the argument and E be the absolute error in the result. (Since Y (x) oscillates about zero,  
0

absolute error and not relative error is significant, except for very small  $x$ .)

If  $(\delta)$  is somewhat larger than the machine representation error (e.g. if  $(\delta)$  is due to data errors etc), then  $E$  and  $(\delta)$  are approximately related by

$$E \sim |xY(x)|(\delta)$$

(provided  $E$  is also within machine bounds). Figure 1 displays the behaviour of the amplification factor  $|xY(x)|$ .

1

Figure 1

Please see figure in printed Reference Manual

However, if  $(\delta)$  is of the same order as the machine representation errors, then rounding errors could make  $E$  slightly larger than the above relation predicts.

For very small  $x$ , the errors are essentially independent of  $(\delta)$  and the routine should provide relative accuracy bounded by the machine precision.

For very large  $x$ , the above relation ceases to apply. In this

region,  $Y(x) \sim \frac{1}{\sqrt{(\pi)x}} \sin(x - \frac{(\pi)}{4})$ . The amplitude  $\frac{1}{\sqrt{(\pi)x}}$  can be calculated with reasonable accuracy for all  $x$ , but  $\sin(x - \frac{(\pi)}{4})$  cannot. If  $x - \frac{(\pi)}{4}$  is written as  $2N(\pi) + (\theta)$

where  $N$  is an integer and  $0 \leq (\theta) < 2(\pi)$ , then  $\sin(x - \frac{(\pi)}{4})$  is

-1

determined by  $(\theta)$  only. If  $x \sim (\delta)$ ,  $(\theta)$  cannot be determined with any accuracy at all. Thus if  $x$  is greater than, or of the order of the inverse of machine precision, it is impossible to calculate the phase of  $Y(x)$  and the routine must

0

fail.

### 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions S17ADF  
 S17ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S17ADF returns the value of the Bessel Function  $Y(x)$ , via the  
 1  
 routine name.

### 2. Specification

```
DOUBLE PRECISION FUNCTION S17ADF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

### 3. Description

This routine evaluates an approximation to the Bessel Function of the second kind  $Y(x)$ .

1

Note:  $Y(x)$  is undefined for  $x \leq 0$  and the routine will fail for  
 1  
 such arguments.

The routine is based on four Chebyshev expansions:

For  $0 < x \leq 8$ ,

$$Y(x) = \frac{1}{(\pi)^2} \ln x - \sum_{r=0}^8 \frac{a_r T_r(t)}{8^{r+1}} - \frac{1}{(\pi)^2} x + \sum_{r=0}^8 \frac{b_r T_r(t)}{8^{r+1}}, \text{ with } t = 2\left(\frac{x}{8}\right) - 1;$$

For  $x > 8$ ,

$$Y(x) = \frac{1}{\sqrt{(\pi)x}} \frac{1}{x} \left\{ \frac{1}{(\pi)^2} \left[ P(x) \sin\left(x - 3\frac{(\pi)}{4}\right) + Q(x) \cos\left(x - 3\frac{(\pi)}{4}\right) \right] \right\}$$

where  $P(x) = \sum_{r=0}^8 \frac{c_r T_r(t)}{8^{r+1}}$ ,

and  $Q(x) = \sum_{r=0}^8 \frac{d_r T_r(t)}{8^{r+1}}$ , with  $t = 2\left(\frac{x}{8}\right) - 1$ .

For  $x$  near zero,  $Y(x) \sim -\frac{1}{(\pi)x}$ . This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision. For extremely small  $x$ , there is a danger of overflow in calculating  $-\frac{1}{(\pi)x}$  and for such arguments the routine will fail.

For very large  $x$ , it becomes impossible to provide results with any reasonable accuracy (see Section 7), hence the routine fails. Such arguments contain insufficient information to determine the

phase of oscillation of  $Y_1(x)$ , only the amplitude,  $\frac{1}{\sqrt{(pi)x^2}}$ , can be determined and this is returned on soft failure. The range for which this occurs is roughly related to machine precision; the routine will fail if  $x \sim 1/\text{machine precision}$  (see the Users' Note for your implementation for details).

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.
- [2] Clenshaw C W (1962) Mathematical Tables. Chebyshev Series for Mathematical Functions. HMSO.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
On entry: the argument x of the function. Constraint: X > 0.0.
- 2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

X is too large. On soft failure the routine returns the

amplitude of the  $Y_1$  oscillation,  $\frac{1}{\sqrt{(pi)x^2}}$ .

IFAIL= 2

X <= 0.0,  $Y_1$  is undefined. On soft failure the routine

returns zero.

IFAIL= 3

X is too close to zero, there is a danger of overflow. On soft failure, the routine returns the value of  $Y(x)$  at the smallest valid argument.

### 7. Accuracy

Let  $(\delta)$  be the relative error in the argument and  $E$  be the absolute error in the result. (Since  $Y(x)$  oscillates about zero, absolute error and not relative error is significant, except for very small  $x$ .)

If  $(\delta)$  is somewhat larger than the machine precision (e.g. if  $(\delta)$  is due to data errors etc), then  $E$  and  $(\delta)$  are approximately related by:

$$E \sim |x Y_0(x) - Y_1(x)| (\delta)$$

(provided  $E$  is also within machine bounds). Figure 1 displays the behaviour of the amplification factor  $|x Y_0(x) - Y_1(x)|$ .

Figure 1

Please see figure in printed Reference Manual

However, if  $(\delta)$  is of the same order as machine precision, then rounding errors could make  $E$  slightly larger than the above relation predicts.

For very small  $x$ , absolute error becomes large, but the relative error in the result is of the same order as  $(\delta)$ .

For very large  $x$ , the above relation ceases to apply. In this region,  $Y(x) \sim \frac{2(\pi)}{x} \sin(x - \frac{3(\pi)}{4})$ . The amplitude  $\frac{2(\pi)}{x}$  can be calculated with reasonable accuracy for all  $x$ , but  $\sin(x - \frac{3(\pi)}{4})$

cannot. If  $x - \frac{\pi}{4}$  is written as  $2N(\pi) + (\theta)$  where  $N$  is an integer and  $0 \leq (\theta) < 2(\pi)$ , then  $\sin(x - \frac{\pi}{4})$  is determined by  $(\theta)$  only. If  $x > (\delta)$ ,  $(\theta)$  cannot be determined with any accuracy at all. Thus if  $x$  is greater than, or of the order of, the inverse of the machine precision, it is impossible to calculate the phase of  $Y(x)$  and the routine must fail.

#### 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

#### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions S17AEF  
 S17AEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S17AEF returns the value of the Bessel Function  $J_0(x)$ , via the routine name.

#### 2. Specification

DOUBLE PRECISION FUNCTION S17AEF (X, IFAIL)  
 INTEGER IFAIL

## DOUBLE PRECISION X

## 3. Description

This routine evaluates an approximation to the Bessel Function of the first kind  $J_0(x)$ .

0

Note:  $J_0(-x) = J_0(x)$ , so the approximation need only consider  $x \geq 0$ .

0 0

The routine is based on three Chebyshev expansions:

For  $0 < x \leq 8$ ,

$$J_0(x) = \sum_{r=0}^{\infty} a_r T_r(t), \text{ with } t = 2\left(\frac{x}{8}\right)^2 - 1.$$

For  $x > 8$ ,

$$J_0(x) = \frac{1}{\sqrt{(\pi)x}} \left\{ \frac{(\pi)}{4} P_0(x) \cos\left(x - \frac{(\pi)}{4}\right) - Q_0(x) \sin\left(x - \frac{(\pi)}{4}\right) \right\}$$

where  $P_0(x) = \sum_{r=0}^{\infty} b_r T_r(t)$ ,

and  $Q_0(x) = \sum_{r=0}^{\infty} c_r T_r(t)$ , with  $t = 2\left(\frac{x}{8}\right)^2 - 1$ .

For  $x$  near zero,  $J_0(x) \sim 1$ . This approximation is used when  $x$  is

sufficiently small for the result to be correct to machine precision.

For very large  $x$ , it becomes impossible to provide results with any reasonable accuracy (see Section 7), hence the routine fails. Such arguments contain insufficient information to determine the

phase of oscillation of  $J_0(x)$ ; only the amplitude,  $\sqrt{\frac{2}{(\pi)|x|}}$ , can be determined and this is returned on soft failure. The range for which this occurs is roughly related to the machine precision; the routine will fail if  $|x| > 1/\text{machine precision}$  (see the Users' Note for your implementation).

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.
- [2] Clenshaw C W (1962) Mathematical Tables. Chebyshev Series for Mathematical Functions. HMSO.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
On entry: the argument x of the function.
- 2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

X is too large. On soft failure the routine returns the

amplitude of the  $J_0$  oscillation,  $\sqrt{\frac{2}{(\pi)|x|}}$ .

#### 7. Accuracy

Let  $(\delta)$  be the relative error in the argument and E be the absolute error in the result. (Since  $J_0(x)$  oscillates about zero,

absolute error and not relative error is significant.)

If (delta) is somewhat larger than the machine precision (e.g. if (delta) is due to data errors etc), then E and (delta) are approximately related by:

$$E \sim |xJ_1(x)|(\delta)$$

(provided E is also within machine bounds). Figure 1 displays the behaviour of the amplification factor  $|xJ_1(x)|$ .

1

Figure 1

Please see figure in printed Reference Manual

However, if (delta) is of the same order as machine precision, then rounding errors could make E slightly larger than the above relation predicts.

For very large x, the above relation ceases to apply. In this

region,  $J_0(x) \sim \frac{1}{\sqrt{(\pi)|x|}} \cos(x - \frac{\pi}{4})$ . The amplitude

$\frac{1}{\sqrt{(\pi)|x|}}$  can be calculated with reasonable accuracy for all x

but  $\cos(x - \frac{\pi}{4})$  cannot. If  $x - \frac{\pi}{4}$  is written as

$2N(\pi) + (\theta)$  where N is an integer and  $0 \leq (\theta) < 2(\pi)$ , then  $\cos(x - \frac{\pi}{4})$  is determined by (theta) only. If  $x \sim (\delta)^{-1}$ ,

(theta) cannot be determined with any accuracy at all. Thus if x is greater than, or of the order of, the inverse of the machine precision, it is impossible to calculate the phase of  $J_0(x)$  and

0

the routine must fail.

## 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S17 -- Approximations of Special Functions S17AFF  
 S17AFF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S17AFF returns the value of the Bessel Function  $J_1(x)$ , via the routine name.

### 2. Specification

```
DOUBLE PRECISION FUNCTION S17AFF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

### 3. Description

This routine evaluates an approximation to the Bessel Function of the first kind  $J_1(x)$ .

Note:  $J_1(-x) = -J_1(x)$ , so the approximation need only consider  $x \geq 0$

The routine is based on three Chebyshev expansions:

For  $0 < x \leq 8$ ,

$$J_1(x) = \frac{x}{8} \int_0^x a(r) T(r) dr, \text{ with } t = 2\left(\frac{x}{8}\right) - 1.$$

For  $x > 8$ ,

$$J_1(x) = \frac{1}{\sqrt{\pi}} \left\{ \frac{1}{4} P(x) \cos\left(x - \frac{3\pi}{4}\right) - Q(x) \sin\left(x - \frac{3\pi}{4}\right) \right\}$$

--',  
where  $P(x) = \int_0^x b(r) T(r) dr$ ,  
and  $Q(x) = \int_0^x c(r) T(r) dr$ , with  $t = 2\left(\frac{x}{8}\right) - 1$ .

For  $x$  near zero,  $J_1(x) \sim -\frac{x}{2}$ . This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision.

For very large  $x$ , it becomes impossible to provide results with any reasonable accuracy (see Section 7), hence the routine fails. Such arguments contain insufficient information to determine the

phase of oscillation of  $J_1(x)$ ; only the amplitude,  $\frac{1}{\sqrt{\pi}} \frac{1}{|x|}$ , can be determined and this is returned on soft failure. The range for which this occurs is roughly related to the machine precision; the routine will fail if  $|x| > 1/\text{machine precision}$  (see the Users' Note for your implementation for details).

 On entry: the argument x of the function.
- 2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

X is too large. On soft failure the routine returns the

amplitude of the  $J_1$  oscillation,  $\frac{1}{\sqrt{2}} \frac{1}{(\pi)|x|}$ .

## 7. Accuracy

Let  $(\delta)$  be the relative error in the argument and E be the absolute error in the result. (Since  $J_1(x)$  oscillates about zero, absolute error and not relative error is significant.)

If  $(\delta)$  is somewhat larger than machine precision (e.g. if  $(\delta)$  is due to data errors etc), then E and  $(\delta)$  are approximately related by:

$$E \approx |x J_0(x) - J_1(x)| (\delta)$$

(provided E is also within machine bounds). Figure 1 displays the behaviour of the amplification factor  $|x J_0(x) - J_1(x)|$ .

0 1

Figure 1

Please see figure in printed Reference Manual

However, if  $(\delta)$  is of the same order as machine precision, then rounding errors could make  $E$  slightly larger than the above relation predicts.

For very large  $x$ , the above relation ceases to apply. In this

region,  $J_1(x) \sim \frac{1}{\sqrt{(\pi)|x|}} \frac{2}{(\pi)^{3/4}} \cos(x - \frac{3\pi}{4})$ . The amplitude

$\frac{2}{\sqrt{(\pi)|x|}}$  can be calculated with reasonable accuracy for all  $x$

but  $\cos(x - \frac{3\pi}{4})$  cannot. If  $x - \frac{3\pi}{4}$  is written as

$2N(\pi) + (\theta)$  where  $N$  is an integer and  $0 \leq (\theta) < 2(\pi)$ , then  $\cos(x - \frac{3\pi}{4})$  is determined by  $(\theta)$  only. If  $x \sim (\delta)$ ,  $(\theta)$  cannot be determined with any accuracy at all. Thus if  $x$

is greater than, or of the order of, machine precision, it is impossible to calculate the phase of  $J_1(x)$  and the routine must

fail.

#### 8. Further Comments

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions S17AGF  
 S17AGF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S17AGF returns a value for the Airy function,  $Ai(x)$ , via the routine name.

### 2. Specification

```
DOUBLE PRECISION FUNCTION S17AGF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

### 3. Description

This routine evaluates an approximation to the Airy function,  $Ai(x)$ . It is based on a number of Chebyshev expansions:

For  $x < -5$ ,

$$Ai(x) = \frac{a(t)\sin z - b(t)\cos z}{(-x)^{1/4}}$$

where  $z = \frac{(\pi)^{2/3}}{4} - \sqrt[3]{-x}$ , and  $a(t)$  and  $b(t)$  are expansions in the variable  $t = -2\sqrt[3]{-x} - 1$ .

For  $-5 \leq x \leq 0$ ,

$$Ai(x) = f(t) - xg(t),$$

where  $f$  and  $g$  are expansions in  $t = -2\left(\frac{x}{5}\right)^{-1}$ .

For  $0 < x < 4.5$ ,

$$Ai(x) = e^{-3x/2} y(t),$$

where  $y$  is an expansion in  $t = 4x/9 - 1$ .

For  $4.5 \leq x < 9$ ,

$$Ai(x) = e^{-5x/2} u(t),$$

where  $u$  is an expansion in  $t = 4x/9 - 3$ .

For  $x \geq 9$ ,

$$Ai(x) = \frac{e^{-z} v(t)}{x^{1/4}},$$

where  $z = \frac{2}{3} \sqrt{x}$  and  $v$  is an expansion in  $t = 2\left(\frac{z}{18}\right)^{-1}$ .

For  $|x| <$  the machine precision, the result is set directly to  $Ai(0)$ . This both saves time and guards against underflow in intermediate calculations.

For large negative arguments, it becomes impossible to calculate the phase of the oscillatory function with any precision and so

the routine must fail. This occurs if  $x < -\left(\frac{2}{3}\right)^{2/3} \frac{1}{2(\epsilon)}$ , where  $\epsilon$  is the machine precision.

For large positive arguments, where  $A_i$  decays in an essentially exponential manner, there is a danger of underflow so the routine must fail.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument x of the function.
- 2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 X is too large and positive. On soft failure, the routine returns zero.

IFAIL= 2  
 X is too large and negative. On soft failure, the routine returns zero.

#### 7. Accuracy

For negative arguments the function is oscillatory and hence absolute error is the appropriate measure. In the positive region the function is essentially exponential-like and here relative error is appropriate. The absolute error, E, and the relative error, (epsilon), are related in principle to the relative error in the argument, (delta), by

$$E \sim |x A_i'(x)| (\delta), \quad (\epsilon) \sim \frac{|x A_i'(x)|}{|A_i(x)|} (\delta).$$

In practice, approximate equality is the best that can be expected. When (delta), (epsilon) or E is of the order of the machine precision, the errors in the result will be somewhat larger.

For small x, errors are strongly damped by the function and hence will be bounded by the machine precision.

For moderate negative x, the error behaviour is oscillatory but the amplitude of the error grows like

$$\text{amplitude} \left( \frac{(E) |x|^{5/4}}{(\text{delta})} \right) \sim \frac{1}{\sqrt{\pi}}.$$

However the phase error will be growing roughly like  $\frac{2}{3} \sqrt{|x|}$

and hence all accuracy will be lost for large negative arguments due to the impossibility of calculating sin and cos to any

$$\text{accuracy if } \frac{2}{3} \sqrt{|x|} > \frac{1}{(\text{delta})}.$$

For large positive arguments, the relative error amplification is considerable:

$$\frac{(\text{epsilon})}{(\text{delta})} \sim \frac{1}{\sqrt{x}}.$$

This means a loss of roughly two decimal places accuracy for arguments in the region of 20. However very large arguments are not possible due to the danger of setting underflow and so the errors are limited in practice.

## 8. Further Comments

None.

### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions S17AHF  
 S17AHF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S17AHF returns a value of the Airy function,  $Bi(x)$ , via the routine name.

### 2. Specification

```
DOUBLE PRECISION FUNCTION S17AHF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

### 3. Description

This routine evaluates an approximation to the Airy function  $Bi(x)$ . It is based on a number of Chebyshev expansions.

For  $x < -5$ ,

$$Bi(x) = \frac{a(t)\cos z + b(t)\sin z}{1/4},$$

$(-x)$

$$\text{where } z = \frac{(\pi)^{2/3}}{4} + \frac{-\sqrt{-x}}{3} \text{ and } a(t) \text{ and } b(t) \text{ are expansions in the}$$

$$\text{variable } t = -2 \left( \frac{5}{x} \right) - 1.$$

For  $-5 \leq x \leq 0$ ,

$$Bi(x) = \sqrt[3]{3(f(t) + xg(t))},$$

$$\text{where } f \text{ and } g \text{ are expansions in } t = -2 \left( \frac{5}{x} \right) - 1.$$

For  $0 < x < 4.5$ ,

$$Bi(x) = e^{\frac{11x}{8}} y(t),$$

$$\text{where } y \text{ is an expansion in } t = 4x/9 - 1.$$

For  $4.5 \leq x \leq 9$ ,

$$Bi(x) = e^{\frac{5x}{2}} v(t),$$

$$\text{where } v \text{ is an expansion in } t = 4x/9 - 3.$$

For  $x \geq 9$ ,

$$Bi(x) = \frac{e^{\frac{z}{4}} u(t)}{x},$$

$$\text{where } z = \frac{2}{3} \sqrt{x} \text{ and } u \text{ is an expansion in } t = 2 \left( \frac{18}{z} \right) - 1.$$

For  $|x| <$  the machine precision, the result is set directly to  $Bi(0)$ . This both saves time and avoids possible intermediate underflows.

For large negative arguments, it becomes impossible to calculate the phase of the oscillating function with any accuracy so the

routine must fail. This occurs if  $x < - \frac{(3)^{2/3}}{(2(\epsilon))}$ , where  $(\epsilon)$  is the machine precision.

For large positive arguments, there is a danger of causing overflow since  $Bi$  grows in an essentially exponential manner, so the routine must fail.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
On entry: the argument  $x$  of the function.
- 2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

X is too large and positive. On soft failure, the routine returns zero.

IFAIL= 2

X is too large and negative. On soft failure, the routine returns zero.

## 7. Accuracy

For negative arguments the function is oscillatory and hence absolute error is the appropriate measure. In the positive region the function is essentially exponential-like and here relative error is appropriate. The absolute error,  $E$ , and the relative error,  $(\epsilon)$ , are related in principle to the relative error in the argument,  $(\delta)$ , by

$$E \sim |x \text{Bi}'(x)| (\delta), \quad (\epsilon) \sim \frac{|x \text{Bi}'(x)|}{|\text{Bi}(x)|} (\delta).$$

In practice, approximate equality is the best that can be expected. When  $(\delta)$ ,  $(\epsilon)$  or  $E$  is of the order of the machine precision, the errors in the result will be somewhat larger.

For small  $x$ , errors are strongly damped and hence will be bounded essentially by the machine precision.

For moderate to large negative  $x$ , the error behaviour is clearly oscillatory but the amplitude of the error grows like amplitude

$$\begin{aligned} & \left( \frac{E}{(\delta)} \right) |x|^{5/4} \\ & \left( \frac{E}{(\delta)} \right) \sim \frac{|x|^{5/4}}{\sqrt{\pi}}. \end{aligned}$$

However the phase error will be growing roughly as  $-\frac{2}{3} \sqrt{|x|}$  and hence all accuracy will be lost for large negative arguments.

This is due to the impossibility of calculating  $\sin$  and  $\cos$  to

$$\text{any accuracy if } -\frac{2}{3} \sqrt{|x|} > \frac{1}{(\delta)}.$$

For large positive arguments, the relative error amplification is considerable:

$$\frac{(\text{epsilon})}{(\text{delta})} \sim \frac{1}{x^3}$$

This means a loss of roughly two decimal places accuracy for arguments in the region of 20. However very large arguments are not possible due to the danger of causing overflow and errors are therefore limited in practice.

#### 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

#### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S17 -- Approximations of Special Functions S17AJF  
 S17AJF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S17AJF returns a value of the derivative of the Airy function  $Ai(x)$ , via the routine name.

#### 2. Specification

```
DOUBLE PRECISION FUNCTION S17AJF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

## 3. Description

This routine evaluates an approximation to the derivative of the Airy function  $Ai(x)$ . It is based on a number of Chebyshev expansions.

For  $x < -5$ ,

$$Ai'(x) = \sqrt[4]{-x} \left[ a(t) \cos z + \frac{b(t)}{(zeta)^3} \sin z \right],$$

where  $z = \frac{\pi}{4} + (zeta)$ ,  $(zeta) = \frac{2}{3} \sqrt[3]{-x}$  and  $a(t)$  and  $b(t)$  are expansions in variable  $t = -2 \left( \frac{5}{x} \right) - 1$ .

For  $-5 \leq x \leq 0$ ,

$$Ai'(x) = x^2 f(t) - g(t),$$

where  $f$  and  $g$  are expansions in  $t = -2 \left( \frac{5}{x} \right) - 1$ .

For  $0 < x < 4.5$ ,

$$Ai'(x) = e^{-11x/8} y(t),$$

where  $y(t)$  is an expansion in  $t = 4 \left( \frac{5}{x} \right) - 1$ .

For  $4.5 \leq x < 9$ ,

$$Ai'(x) = e^{-5x/2} v(t),$$

( x )

where  $v(t)$  is an expansion in  $t=4(-)-3$ .  
( 9)

For  $x \geq 9$ ,

$$Ai'(x) = \sqrt[4]{-xe^{-z}} u(t),$$

where  $z = \sqrt[2]{x} / 3$  and  $u(t)$  is an expansion in  $t = 2(\sqrt[3]{z}) - 1$ .  
( 18)  
( z )

For  $|x| <$  the square of the machine precision, the result is set directly to  $Ai'(0)$ . This both saves time and avoids possible intermediate underflows.

For large negative arguments, it becomes impossible to calculate a result for the oscillating function with any accuracy and so

4/7  
( )  
( \/(pi) )

the routine must fail. This occurs for  $x < -(\frac{4}{7\epsilon})$ , where  
( (epsilon))

(epsilon) is the machine precision.

For large positive arguments, where  $Ai'$  decays in an essentially exponential manner, there is a danger of underflow so the routine must fail.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

1: X -- DOUBLE PRECISION Input  
On entry: the argument  $x$  of the function.

2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see

Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

X is too large and positive. On soft failure, the routine returns zero.

IFAIL= 2

X is too large and negative. On soft failure, the routine returns zero.

## 7. Accuracy

For negative arguments the function is oscillatory and hence absolute error is the appropriate measure. In the positive region the function is essentially exponential in character and here relative error is needed. The absolute error, E, and the relative error, (epsilon), are related in principle to the relative error in the argument, (delta), by

$$E \sim |x| \text{Ai}(x) |(\delta)|^2 \quad (\epsilon) \sim \frac{|x| \text{Ai}(x)|^2}{|\text{Ai}'(x)|} |(\delta)|.$$

In practice, approximate equality is the best that can be expected. When (delta), (epsilon) or E is of the order of the machine precision, the errors in the result will be somewhat larger.

For small x, positive or negative, errors are strongly attenuated by the function and hence will be roughly bounded by the machine precision.

For moderate to large negative x, the error, like the function, is oscillatory; however the amplitude of the error grows like

$$\frac{|x|^{7/4}}{\sqrt{\pi}}.$$

Therefore it becomes impossible to calculate the function with

$$\text{any accuracy if } |x| > \frac{7/4 \sqrt{\pi}}{(\delta)}.$$

For large positive  $x$ , the relative error amplification is considerable:

$$\frac{(\epsilon)}{(\delta)} \sim \frac{1}{3} \sqrt{x}.$$

However, very large arguments are not possible due to the danger of underflow. Thus in practice error amplification is limited.

#### 8. Further Comments

None.

#### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S17 -- Approximations of Special Functions

S17AKF

S17AKF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S17AKF returns a value for the derivative of the Airy function

Bi(x), via the routine name.

## 2. Specification

```
DOUBLE PRECISION FUNCTION S17AKF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

## 3. Description

This routine calculates an approximate value for the derivative of the Airy function Bi(x). It is based on a number of Chebyshev expansions.

For  $x < -5$ ,

$$\text{Bi}'(x) = \sqrt{-x} \left[ -a(t) \sin z + \frac{b(t)}{(zeta)} \cos z \right],$$

where  $z = \frac{\pi}{4} + (zeta)$ ,  $(zeta) = \frac{2}{3} \sqrt{-x}$  and  $a(t)$  and  $b(t)$  are expansions in the variable  $t = -2 \left( \frac{5}{x} \right) - 1$ .

For  $-5 \leq x \leq 0$ ,

$$\text{Bi}'(x) = \sqrt{3} (x f(t) + g(t)),$$

where  $f$  and  $g$  are expansions in  $t = -2 \left( \frac{5}{x} \right) - 1$ .

For  $0 < x < 4.5$ ,

$$\text{Bi}'(x) = e^{3x/2} y(t),$$

where  $y(t)$  is an expansion in  $t = 4x/9 - 1$ .

For  $4.5 \leq x < 9$ ,

$$Bi'(x) = e^{21x/8} u(t),$$

where  $u(t)$  is an expansion in  $t = 4x/9 - 3$ .

For  $x \geq 9$ ,

$$Bi'(x) = \sqrt[4]{x} e^z v(t),$$

where  $z = -\sqrt[3]{x}$  and  $v(t)$  is an expansion in  $t = 2\left(\frac{18}{z}\right) - 1$ .

For  $|x| <$  the square of the machine precision, the result is set directly to  $Bi'(0)$ . This saves time and avoids possible underflows in calculation.

For large negative arguments, it becomes impossible to calculate a result for the oscillating function with any accuracy so the

routine must fail. This occurs for  $x < -\left(\frac{4/7}{\sqrt[4]{\pi}}\right)^{4/7}$ , where  $(\epsilon)$  is the machine precision.

For large positive arguments, where  $Bi'$  grows in an essentially exponential manner, there is a danger of overflow so the routine must fail.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- |                                           |              |
|-------------------------------------------|--------------|
| 1: X -- DOUBLE PRECISION                  | Input        |
| On entry: the argument x of the function. |              |
| 2: IFAIL -- INTEGER                       | Input/Output |

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

X is too large and positive. On soft failure the routine returns zero.

IFAIL= 2

X is too large and negative. On soft failure the routine returns zero.

## 7. Accuracy

For negative arguments the function is oscillatory and hence absolute error is appropriate. In the positive region the function has essentially exponential behaviour and hence relative error is needed. The absolute error, E, and the relative error (epsilon), are related in principle to the relative error in the argument (delta), by

$$E \sim |x| \text{Bi}(x) (\delta)^2 \quad (\epsilon) \sim \frac{|x| \text{Bi}(x)|^2}{|\text{Bi}'(x)|} (\delta).$$

In practice, approximate equality is the best that can be expected. When (delta), (epsilon) or E is of the order of the machine precision, the errors in the result will be somewhat larger.

For small x, positive or negative, errors are strongly attenuated by the function and hence will effectively be bounded by the machine precision.

For moderate to large negative x, the error is, like the function, oscillatory. However, the amplitude of the absolute

error grows like  $\frac{|x|^{7/4}}{}$ . Therefore it becomes impossible to

$$\sqrt[7]{\pi}$$

calculate the function with any accuracy if  $|x| > \frac{7/4 \sqrt[7]{\pi}}{(\delta)}$ .

For large positive  $x$ , the relative error amplification is

considerable:  $\frac{(\epsilon)}{(\delta)} / 3 \sqrt[7]{x}$ . However, very large arguments are not possible due to the danger of overflow. Thus in practice the actual amplification that occurs is limited.

#### 8. Further Comments

None.

#### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions

S17DCF

S17DCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S17DCF returns a sequence of values for the Bessel functions  $Y_n(z)$  for complex  $z$ , non-negative  $(nu)$  and  $n=0,1,\dots,N-1$ ,  $(nu)+n$

with an option for exponential scaling.

## 2. Specification

```

SUBROUTINE S17DCF (FNU, Z, N, SCALE, CY, NZ, CWRK, IFAIL)
INTEGER N, NZ, IFAIL
DOUBLE PRECISION FNU
COMPLEX(KIND(1.0D0)) Z, CY(N), CWRK(N)
CHARACTER*1 SCALE

```

## 3. Description

This subroutine evaluates a sequence of values for the Bessel function  $Y_{(\nu)}(z)$ , where  $z$  is complex,  $-(\pi) < \arg z \leq (\pi)$ , and  $(\nu)$

$(\nu)$  is the real, non-negative order. The  $N$ -member sequence is generated for orders  $(\nu)$ ,  $(\nu)+1, \dots, (\nu)+N-1$ . Optionally, the sequence is scaled by the factor  $e^{-|\operatorname{Im} z|}$ .

Note: although the routine may not be called with  $(\nu)$  less than zero, for negative orders the formula  $Y_{-(\nu)}(z) = Y_{(\nu)}(z) \cos((\pi)(\nu)) + J_{(\nu)}(z) \sin((\pi)(\nu))$  may be used (for the Bessel function  $J_{(\nu)}(z)$ , see S17DEF).

The routine is derived from the routine CBESY in Amos [2]. It is based on the relation  $Y_{(\nu)}^{(1)}(z) = \frac{H_{(\nu)}^{(1)}(z) - H_{(\nu)}^{(2)}(z)}{2i}$ , where  $H_{(\nu)}^{(1)}(z)$  and  $H_{(\nu)}^{(2)}(z)$  are the Hankel functions of the first and second kinds respectively (see S17DLF).

When  $N$  is greater than 1, extra values of  $Y_{(\nu)}(z)$  are computed using recurrence relations.

For very large  $|z|$  or  $((\nu)+N-1)$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller  $|z|$  or  $((\nu)+N-1)$ , the computation is performed but results are accurate to less than half of machine precision.

If  $|z|$  is very small, near the machine underflow threshold, or  $((nu)+N-1)$  is too large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

#### 4. References

- [2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

#### 5. Parameters

- 1: FNU -- DOUBLE PRECISION Input  
On entry: the order, (nu), of the first member of the sequence of functions. Constraint: FNU  $\geq$  0.0.
- 2: Z -- COMPLEX(KIND(1.0D0)) Input  
On entry: the argument, z, of the functions. Constraint: Z  $\neq$  (0.0, 0.0).
- 3: N -- INTEGER Input  
On entry: the number, N, of members required in the sequence  $Y_{(nu)}(z), Y_{(nu)+1}(z), \dots, Y_{(nu)+N-1}(z)$ . Constraint: N  $\geq$  1.
- 4: SCALE -- CHARACTER\*1 Input  
On entry: the scaling option.  
  
If SCALE = 'U', the results are returned unscaled.  
  
If SCALE = 'S', the results are returned scaled by the factor  $e^{-|\text{Im}z|}$ . Constraint: SCALE = 'U' or 'S'.
- 5: CY(N) -- COMPLEX(KIND(1.0D)) array Output  
On exit: the N required function values: CY(i) contains  $Y_{(nu)+i-1}(z)$ , for  $i=1,2,\dots,N$ .
- 6: NZ -- INTEGER Output  
On exit: the number of components of CY that are set to zero due to underflow. The positions of such components in the

array CY are arbitrary.

7: CWRK(N) -- COMPLEX(KIND(1.0D)) array Workspace

8: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry FNU < 0.0,

or  $Z = (0.0, 0.0)$ ,

or  $N < 1$ ,

or SCALE /= 'U' or 'S'.

IFAIL= 2

No computation has been performed due to the likelihood of overflow, because ABS(Z) is less than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 3

No computation has been performed due to the likelihood of overflow, because FNU + N - 1 is too large - how large depends on Z as well as the overflow threshold of the machine.

IFAIL= 4

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by S17DCF are accurate to less than half of machine precision. This error exit may occur if either ABS(Z) or FNU + N - 1 is greater than a machine-

dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S17DCF would be lost. This error exit may occur if either  $ABS(Z)$  or  $FNU + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 6

No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S17DCF would have caused overflow or underflow.

## 7. Accuracy

All constants in subroutine S17DCF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the maximum number of correct digits in the results obtained is limited by  $p = \min(t, 18)$ . Because of errors in argument reduction when computing elementary functions inside S17DCF, the actual number of correct digits is limited, in general, by  $p - s$ , where  $s \sim \max(1, \log_{10} |z|, \log_{10} (nu))$  represents the number of digits

lost due to the argument reduction. Thus the larger the values of  $|z|$  and  $(nu)$ , the less the precision in the result. If S17DCF is called with  $N > 1$ , then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S17DCF with different base values of  $(nu)$  and different  $N$ , the computed values may not agree exactly. Empirical tests with modest values of  $(nu)$  and  $z$  have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

## 8. Further Comments

The time taken by the routine for a call of S17DCF is approximately proportional to the value of  $N$ , plus a constant. In general it is much cheaper to call S17DCF with  $N$  greater than 1, rather than to make  $N$  separate calls to S17DCF.

Paradoxically, for some values of  $z$  and  $(nu)$ , it is cheaper to call S17DCF with a larger value of  $N$  than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different  $N$ , and the costs in each region may differ greatly.

Note that if the function required is  $Y_0(x)$  or  $Y_1(x)$ , i.e.,  $(nu) = 0.0$  or  $1.0$ , where  $x$  is real and positive, and only a single unscaled function value is required, then it may be much cheaper to call S17ACF or S17ADF respectively.

#### 9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the order FNU, the second is a complex value for the argument,  $Z$ , and the third is a value for the parameter SCALE. The program calls the routine with  $N = 2$  to evaluate the function for orders FNU and FNU + 1, and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions S17DEF  
 S17DEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S17DEF returns a sequence of values for the Bessel functions  $J_n(z)$  for complex  $z$ , non-negative  $(nu)$  and  $n=0,1,\dots,N-1$ ,  $(nu)+n$  with an option for exponential scaling.

## 2. Specification

```

SUBROUTINE S17DEF (FNU, Z, N, SCALE, CY, NZ, IFAIL)
 INTEGER N, NZ, IFAIL
 DOUBLE PRECISION FNU
 COMPLEX(KIND(1.0D0)) Z, CY(N)
 CHARACTER*1 SCALE

```

## 3. Description

This subroutine evaluates a sequence of values for the Bessel function  $J_{(\text{nu})}(z)$ , where  $z$  is complex,  $-(\pi) < \arg z \leq (\pi)$ , and

$(\text{nu})$  is the real, non-negative order. The  $N$ -member sequence is generated for orders  $(\text{nu})$ ,  $(\text{nu})+1, \dots, (\text{nu})+N-1$ . Optionally, the sequence is scaled by the factor  $e^{-|\text{Im } z|}$ .

Note: although the routine may not be called with  $(\text{nu})$  less than zero, for negative orders the formula  $J_{-(\text{nu})}(z) = J_{(\text{nu})}(z) \cos((\pi)(\text{nu})) - Y_{(\text{nu})}(z) \sin((\pi)(\text{nu}))$  may be used (for the Bessel function  $Y_{(\text{nu})}(z)$ , see S17DCF).

The routine is derived from the routine CBESJ in Amos [2]. It is based on the relations  $J_{(\text{nu})}(z) = e^{(\text{nu})(\pi)i/2} I_{(\text{nu})}(-iz)$ ,  $\text{Im } z \geq 0.0$  and  $J_{(\text{nu})}(z) = e^{-(\text{nu})(\pi)i/2} I_{(\text{nu})}(iz)$ ,  $\text{Im } z < 0.0$ .

The Bessel function  $I_{(\text{nu})}(z)$  is computed using a variety of techniques depending on the region under consideration.

When  $N$  is greater than 1, extra values of  $J_{(\text{nu})}(z)$  are computed using recurrence relations.

For very large  $|z|$  or  $((\text{nu})+N-1)$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller  $|z|$  or  $((\text{nu})+N-1)$ , the computation is performed but results are accurate to less than half of machine precision.

If  $\text{Im } z$  is large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

#### 5. Parameters

- 1: FNU -- DOUBLE PRECISION Input  
On entry: the order, (nu), of the first member of the sequence of functions. Constraint: FNU  $\geq$  0.0.
- 2: Z -- COMPLEX(KIND(1.0D0)) Input  
On entry: the argument  $z$  of the functions.
- 3: N -- INTEGER Input  
On entry: the number, N, of members required in the sequence  $J_{(z)}, J_{(z)}, \dots, J_{(z)}$ . Constraint: N  $\geq$  1.  
 $(nu) \quad (nu)+1 \quad (nu)+N-1$
- 4: SCALE -- CHARACTER\*1 Input  
On entry: the scaling option.  
If SCALE = 'U', the results are returned unscaled.  
  
If SCALE = 'S', the results are returned scaled by the  $-|\text{Im}z|$  factor  $e$  .  
Constraint: SCALE = 'U' or 'S'.
- 5: CY(N) -- COMPLEX(KIND(1.0D0)) array Output  
On exit: the N required function values: CY(i) contains  $J_{(z)}$ , for  $i=1,2,\dots,N$ .  
 $(nu)+i-1$
- 6: NZ -- INTEGER Output  
On exit: the number of components of CY that are set to zero due to underflow. If NZ  $>$  0, then elements CY(N-NZ+1), CY(N-NZ+2), ..., CY(N) are set to zero.

7: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry FNU < 0.0,

or  $N < 1$ ,

or SCALE /= 'U' or 'S'.

IFAIL= 2

No computation has been performed due to the likelihood of overflow, because  $\text{Im } Z$  is larger than a machine-dependent threshold value (given in the Users' Note for your implementation). This error exit can only occur when SCALE = 'U'.

IFAIL= 3

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by S17DEF are accurate to less than half of machine precision. This error exit may occur if either  $\text{ABS}(Z)$  or  $\text{FNU} + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 4

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S17DEF would be lost. This error exit may occur when either  $\text{ABS}(Z)$  or  $\text{FNU} + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5

No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S17DEF would have caused overflow or underflow.

## 7. Accuracy

All constants in subroutine S17DEF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the maximum number of correct digits in the results obtained is limited by  $p = \min(t, 18)$ . Because of errors in argument reduction when computing elementary functions inside S17DEF, the actual number of correct digits is limited, in general, by  $p - s$ , where  $s \sim \max(1, \log_{10}(|z|), \log_{10}(\nu))$  represents the number of digits

lost due to the argument reduction. Thus the larger the values of  $|z|$  and  $(\nu)$ , the less the precision in the result. If S17DEF is called with  $N > 1$ , then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S17DEF with different base values of  $(\nu)$  and different  $N$ , the computed values may not agree exactly. Empirical tests with modest values of  $(\nu)$  and  $z$  have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

## 8. Further Comments

The time taken by the routine for a call of S17DEF is approximately proportional to the value of  $N$ , plus a constant. In general it is much cheaper to call S17DEF with  $N$  greater than 1, rather than to make  $N$  separate calls to S17DEF.

Paradoxically, for some values of  $z$  and  $(\nu)$ , it is cheaper to call S17DEF with a larger value of  $N$  than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different  $N$ , and the costs in each region may differ greatly.

Note that if the function required is  $J(x)$  or  $J'(x)$ , i.e.,  $(\nu)$

0 1

= 0.0 or 1.0, where  $x$  is real and positive, and only a single unscaled function value is required, then it may be much cheaper to call S17AEF or S17AFF respectively.

### 9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the order FNU, the second is a complex value for the argument,  $Z$ , and the third is a value for the parameter SCALE.

The program calls the routine with  $N = 2$  to evaluate the function for orders FNU and FNU + 1, and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S17 -- Approximations of Special Functions S17DGF  
 S17DGF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S17DGF returns the value of the Airy function  $Ai(z)$  or its derivative  $Ai'(z)$  for complex  $z$ , with an option for exponential scaling.

### 2. Specification

```
SUBROUTINE S17DGF (DERIV, Z, SCALE, AI, NZ, IFAIL)
 INTEGER NZ, IFAIL
 COMPLEX(KIND(1.0D0)) Z, AI
 CHARACTER*1 DERIV, SCALE
```

### 3. Description

This subroutine returns a value for the Airy function  $Ai(z)$  or

its derivative  $Ai'(z)$ , where  $z$  is complex,  $-(\pi) < \arg z \leq (\pi)$ .

Optionally, the value is scaled by the factor  $e^{2z\sqrt{z}/3}$ .

The routine is derived from the routine CAIRY in Amos [2]. It is

based on the relations  $Ai(z) = \frac{\sqrt{z} K_{1/3}(w)}{(\pi)^{1/3}}$ , and  $Ai'(z) = \frac{-z K_{2/3}(w)}{(\pi)^{2/3}}$ ,

where  $K_{(\nu)}$  is the modified Bessel function and  $w=2z\sqrt{z}/3$ .

For very large  $|z|$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller  $|z|$ , the computation is performed but results are accurate to less than half of machine precision. If  $\text{Re } w$  is too large, and the unscaled function is required, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.
- [2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

#### 5. Parameters

- 1: DERIV -- CHARACTER\*1 Input  
 On entry: specifies whether the function or its derivative is required.  
 If DERIV = 'F',  $Ai(z)$  is returned.  
 If DERIV = 'D',  $Ai'(z)$  is returned.  
 Constraint: DERIV = 'F' or 'D'.

- 2: Z -- COMPLEX(KIND(1.0D0)) Input  
 On entry: the argument z of the function.
- 3: SCALE -- CHARACTER\*1 Input  
 On entry: the scaling option.
- If SCALE = 'U', the result is returned unscaled.
- If SCALE = 'S', the result is returned scaled by the factor
- $2z\backslash/z/3$
- e . Constraint: SCALE = 'U' or 'S'.
- 4: AI -- COMPLEX(KIND(1.0D0)) Output  
 On exit: the required function or derivative value.
- 5: NZ -- INTEGER Output  
 On exit: NZ indicates whether or not AI is set to zero due to underflow. This can only occur when SCALE = 'U'.
- If NZ = 0, AI is not set to zero.
- If NZ = 1, AI is set to zero.
- 6: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry DERIV /= 'F' or 'D'.

or SCALE /= 'U' or 'S'.

IFAIL= 2

No computation has been performed due to the likelihood of

overflow, because  $\text{Re } w$  is too large, where  $w=2Z\sqrt{Z}/3$  -- how large depends on  $Z$  and the overflow threshold of the machine. This error exit can only occur when  $\text{SCALE} = 'U'$ .

IFAIL= 3

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the result returned by S17DGF is accurate to less than half of machine precision. This error exit may occur if  $\text{ABS}(Z)$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 4

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in the result returned by S17DGF would be lost. This error exit may occur if  $\text{ABS}(Z)$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5

No result is returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S17DGF would have caused overflow or underflow.

## 7. Accuracy

All constants in subroutine S17DGF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the maximum number of correct digits in the results obtained is limited by  $p=\min(t,18)$ . Because of errors in argument reduction when computing elementary functions inside S17DGF, the actual number of correct digits is limited, in general, by  $p-s$ , where  $s \sim \max(1, |\log |z||)$  represents the number of digits lost due to

10

the argument reduction. Thus the larger the value of  $|z|$ , the less the precision in the result.

Empirical tests with modest values of  $z$ , checking relations between Airy functions  $\text{Ai}(z)$ ,  $\text{Ai}'(z)$ ,  $\text{Bi}(z)$  and  $\text{Bi}'(z)$ , have

shown errors limited to the least significant 3-4 digits of precision.

#### 8. Further Comments

Note that if the function is required to operate on a real argument only, then it may be much cheaper to call S17AGF or S17AJF.

#### 9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the parameter DERIV, the second is a complex value for the argument, Z, and the third is a value for the parameter SCALE. The program calls the routine and prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions S17DHF  
 S17DHF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S17DHF returns the value of the Airy function  $Bi(z)$  or its derivative  $Bi'(z)$  for complex  $z$ , with an option for exponential scaling.

#### 2. Specification

```
SUBROUTINE S17DHF (DERIV, Z, SCALE, BI, IFAIL)
 INTEGER IFAIL
 COMPLEX(KIND(1.0D0)) Z, BI
 CHARACTER*1 DERIV, SCALE
```

### 3. Description

This subroutine returns a value for the Airy function  $\text{Bi}(z)$  or its derivative  $\text{Bi}'(z)$ , where  $z$  is complex,  $-(\pi) < \arg z \leq (\pi)$ .

Optionally, the value is scaled by the factor  $e^{\frac{1}{3}\text{Re}(2z\sqrt{z/3})}$ .

The routine is derived from the routine CBIRY in Amos [2]. It is

based on the relations  $\text{Bi}(z) = \frac{\sqrt{z}}{\sqrt{3}} \left( I_{-1/3}(w) + I_{1/3}(w) \right)$ , and

$$\text{Bi}'(z) = \frac{z}{\sqrt{3}} \left( I_{-2/3}(w) + I_{2/3}(w) \right), \text{ where } I_{\nu}(w) \text{ is the modified Bessel function}$$

function and  $w = 2z\sqrt{z/3}$ .

For very large  $|z|$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller  $|z|$ , the computation is performed but results are accurate to less than half of machine precision. If  $\text{Re } z$  is too large, and the unscaled function is required, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

### 4. References

- [2] Hammersley J M and Handscomb D C (1967) Monte-Carlo Methods. Methuen.

### 5. Parameters

1: DERIV -- CHARACTER\*1 Input  
 On entry: specifies whether the function or its derivative is required.

If DERIV = 'F', Bi(z) is returned.

If DERIV = 'D', Bi'(z) is returned.

Constraint: DERIV = 'F' or 'D'.

2: Z -- COMPLEX(KIND(1.0D0)) Input  
On entry: the argument z of the function.

3: SCALE -- CHARACTER\*1 Input  
On entry: the scaling option.  
If SCALE = 'U', the result is returned unscaled.

If SCALE = 'S', the result is returned scaled by the

$| \operatorname{Re}(2z \backslash z/3) |$   
factor e .  
Constraint: SCALE = 'U' or 'S'.

4: BI -- COMPLEX(KIND(1.0D0)) Output  
On exit: the required function or derivative value.

5: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry DERIV /= 'F' or 'D'.

or SCALE /= 'U' or 'S'.

IFAIL= 2

No computation has been performed due to the likelihood of overflow, because real(Z) is too large - how large depends on the overflow threshold of the machine. This error exit

can only occur when SCALE = 'U'.

IFAIL= 3

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the result returned by S17DHF is accurate to less than half of machine precision. This error exit may occur if  $ABS(Z)$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 4

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in the result returned by S17DHF would be lost. This error exit may occur if  $ABS(Z)$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5

No result is returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S17DHF would have caused overflow or underflow.

## 7. Accuracy

All constants in subroutine S17DHF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the maximum number of correct digits in the results obtained is limited by  $p = \min(t, 18)$ . Because of errors in argument reduction when computing elementary functions inside S17DHF, the actual number of correct digits is limited, in general, by  $p - s$ , where  $s \sim \max(1, |\log_{10} |z||)$  represents the number of digits lost due to

the argument reduction. Thus the larger the value of  $|z|$ , the less the precision in the result.

Empirical tests with modest values of  $z$ , checking relations between Airy functions  $Ai(z)$ ,  $Ai'(z)$ ,  $Bi(z)$  and  $Bi'(z)$ , have shown errors limited to the least significant 3-4 digits of precision.

## 8. Further Comments

Note that if the function is required to operate on a real

argument only, then it may be much cheaper to call S17AHF or S17AKF.

### 9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the parameter DERIV, the second is a complex value for the argument, Z, and the third is a value for the parameter SCALE. The program calls the routine and prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S17 -- Approximations of Special Functions S17DLF  
 S17DLF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S17DLF returns a sequence of values for the Hankel functions  
 (1) (2)  
 $H_{(\nu)}^{(1)}(z)$  or  $H_{(\nu)}^{(2)}(z)$  for complex  $z$ , non-negative  $(\nu)$  and  
 $(\nu)+n$   $(\nu)+n$   
 $n=0,1,\dots,N-1$ , with an option for exponential scaling.

### 2. Specification

```

SUBROUTINE S17DLF (M, FNU, Z, N, SCALE, CY, NZ, IFAIL)
 INTEGER M, N, NZ, IFAIL
 DOUBLE PRECISION FNU
 COMPLEX(KIND(1.0D0)) Z, CY(N)
 CHARACTER*1 SCALE

```

### 3. Description

This subroutine evaluates a sequence of values for the Hankel function  $H_{(\nu)}^{(1)}(z)$  or  $H_{(\nu)}^{(2)}(z)$ , where  $z$  is complex,  $-(\pi) < \arg z \leq (\pi)$ , and  $(\nu)$  is the real, non-negative order. The  $N$ -member sequence is generated for orders  $(\nu)$ ,  $(\nu)+1, \dots, (\nu)+N-1$ .

Optionally, the sequence is scaled by the factor  $e^{-iz}$  if the function is  $H_{(\nu)}^{(1)}(z)$  or by the factor  $e^{iz}$  if the function is  $H_{(\nu)}^{(2)}(z)$ .

Note: although the routine may not be called with  $(\nu)$  less than zero, for negative orders the formulae

$H_{(\nu)}^{(1)}(z) = e^{(\nu)(\pi)i} H_{(\nu)}^{(1)}(z)$ , and  $H_{(\nu)}^{(2)}(z) = e^{-(\nu)(\pi)i} H_{(\nu)}^{(2)}(z)$  may be used.

The routine is derived from the routine CBESH in Amos [2]. It is based on the relation

$$H_{(\nu)}^{(m)}(z) = -e^{\frac{1}{2}p(\nu)} K_{(\nu)}^{(p)}(ze^{\frac{1}{2}p(\nu)}),$$

where  $p=i$  if  $m=1$  and  $p=-i$  if  $m=2$ , and the Bessel function  $K_{(\nu)}(z)$  is computed in the right half-plane only.

Continuation of  $K_{(\nu)}(z)$  to the left half-plane is computed in terms of the Bessel function  $I_{(\nu)}(z)$ . These functions are evaluated using a variety of different techniques, depending on the region under consideration.

When  $N$  is greater than 1, extra values of  $H_{(\nu)}^{(m)}(z)$  are computed using recurrence relations.

For very large  $|z|$  or  $((nu)+N-1)$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller  $|z|$  or  $((nu)+N-1)$ , the computation is performed but results are accurate to less than half of machine precision. If  $|z|$  is very small, near the machine underflow threshold, or  $((nu)+N-1)$  is too large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.
- [2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

#### 5. Parameters

- 1: M -- INTEGER Input  
 On entry: the kind of functions required.  

(1)

 If M = 1, the functions are  $H_{(nu)}^{(1)}(z)$ .  

(2)

 If M = 2, the functions are  $H_{(nu)}^{(2)}(z)$ .  

(nu)

 Constraint: M = 1 or 2.
- 2: FNU -- DOUBLE PRECISION Input  
 On entry: the order, (nu), of the first member of the sequence of functions. Constraint: FNU >= 0.0.
- 3: Z -- COMPLEX(KIND(1.0D0)) Input  
 On entry: the argument z of the functions. Constraint: Z /= (0.0, 0.0).
- 4: N -- INTEGER Input  
 On entry: the number, N, of members required in the sequence  

(M)        (M)        (M)

 $H_{(nu)}^{(M)}, H_{(nu)+1}^{(M)}, \dots, H_{(nu)+N-1}^{(M)}$ . Constraint: N >= 1.
- 5: SCALE -- CHARACTER\*1 Input

On entry: the scaling option.

If SCALE = 'U', the results are returned unscaled.

If SCALE = 'S', the results are returned scaled by the  
 $e^{-iz}$  when  $M = 1$ , or by the factor  $e^{iz}$  when  $M = 2$ .

Constraint: SCALE = 'U' or 'S'.

6: CY(N) -- COMPLEX(KIND(1.0D)) array Output

On exit: the N required function values: CY(i) contains  
 (M)

$H$ , for  $i=1,2,\dots,N$ .  
 (nu)+i-1

7: NZ -- INTEGER Output

On exit: the number of components of CY that are set to zero due to underflow. If  $NZ > 0$ , then if  $\text{Im}z > 0.0$  and  $M = 1$ , or  $\text{Im}z < 0.0$  and  $M = 2$ , elements CY(1), CY(2), ..., CY(NZ) are set to zero. In the complementary half-planes, NZ simply states the number of underflows, and not which elements they are.

8: IFAIL -- INTEGER Input/Output

On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry  $M \neq 1$  and  $M \neq 2$ ,

or  $\text{FNU} < 0.0$ ,

or  $Z = (0.0, 0.0)$ ,

or  $N < 1$ ,

or           SCALE /= 'U' or 'S'.

IFAIL= 2

No computation has been performed due to the likelihood of overflow, because  $\text{ABS}(Z)$  is less than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 3

No computation has been performed due to the likelihood of overflow, because  $\text{FNU} + N - 1$  is too large - how large depends on  $Z$  and the overflow threshold of the machine.

IFAIL= 4

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by S17DLF are accurate to less than half of machine precision. This error exit may occur if either  $\text{ABS}(Z)$  or  $\text{FNU} + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S17DLF would be lost. This error exit may occur when either of  $\text{ABS}(Z)$  or  $\text{FNU} + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 6

No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S17DLF would have caused overflow or underflow.

## 7. Accuracy

All constants in subroutine S17DLF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the maximum number of correct digits in the results obtained is limited by  $p = \min(t, 18)$ . Because of errors in argument reduction when computing elementary functions inside S17DLF, the actual number of correct digits is limited, in general, by  $p - s$ , where  $s = \max(1, \lceil \log |z| \rceil, \lceil \log (\text{nu}) \rceil)$  represents the number of digits

10                    10

lost due to the argument reduction. Thus the larger the values of  $|z|$  and  $(nu)$ , the less the precision in the result. If S17DLF is called with  $N > 1$ , then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S17DLF with different base values of  $(nu)$  and different  $N$ , the computed values may not agree exactly. Empirical tests with modest values of  $(nu)$  and  $z$  have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

#### 8. Further Comments

The time taken by the routine for a call of S17DLF is approximately proportional to the value of  $N$ , plus a constant. In general it is much cheaper to call S17DLF with  $N$  greater than 1, rather than to make  $N$  separate calls to S17DLF.

Paradoxically, for some values of  $z$  and  $(nu)$ , it is cheaper to call S17DLF with a larger value of  $N$  than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different  $N$ , and the costs in each region may differ greatly.

#### 9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the kind of function,  $M$ , the second is a value for the order  $FNU$ , the third is a complex value for the argument,  $Z$ , and the fourth is a value for the parameter  $SCALE$ . The program calls the routine with  $N = 2$  to evaluate the function for orders  $FNU$  and  $FNU + 1$ , and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S18 -- Approximations of Special Functions

S18ACF

## S18ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

S18ACF returns the value of the modified Bessel Function  $K_0(x)$ , via the routine name.

## 2. Specification

```
DOUBLE PRECISION FUNCTION S18ACF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

## 3. Description

This routine evaluates an approximation to the modified Bessel Function of the second kind  $K_0(x)$ .

Note:  $K_0(x)$  is undefined for  $x \leq 0$  and the routine will fail for such arguments.

The routine is based on five Chebyshev expansions:

For  $0 < x \leq 1$ ,

$$K_0(x) = -\ln x + \sum_{r=0}^{\infty} a_r T_r(t) + \sum_{r=0}^{\infty} b_r T_r(t), \text{ where } t = 2x - 1;$$

For  $1 < x \leq 2$ ,

$$K_0(x) = e^{-x} + \sum_{r=0}^{\infty} c_r T_r(t), \text{ where } t = 2x - 3;$$

For  $2 < x \leq 4$ ,

$$K_0(x) = e^{-x} \int_0^x T(t) dt, \text{ where } t = x-3; \\ r=0$$

For  $x > 4$ ,

$$K_0(x) = e^{-x} \int_{\sqrt{x}}^9 T(t) dt, \text{ where } t = \frac{9-x}{1+x}; \\ r=0$$

For  $x$  near zero,  $K_0(x) \sim -(\gamma) - \ln(-)$ , where  $(\gamma)$  denotes Euler's constant. This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision.

For large  $x$ , where there is a danger of underflow due to the smallness of  $K_0$ , the result is set exactly to zero.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument  $x$  of the function. Constraint:  $X > 0$ .  
 0.
- 2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 X <= 0.0, K is undefined. On soft failure the routine  
 0  
 returns zero.

## 7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e., if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

$$(\epsilon) \sim \frac{|xK(x)|}{|K(x)|} (\delta).$$

Figure 1 shows the behaviour of the error amplification factor

$$\frac{|xK(x)|}{|K(x)|}$$

Figure 1

Please see figure in printed Reference Manual

However, if (delta) is of the same order as machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

For small x, the amplification factor is approximately  $\frac{1}{\ln x}$ , which implies strong attenuation of the error, but in general (epsilon) can never be less than the machine precision.

For large x,  $(\epsilon) \sim x(\delta)$  and we have strong amplification of the relative error. Eventually K, which is asymptotically

$$e$$
given by  $---$ , becomes so small that it cannot be calculated

$$\sqrt{x}$$
without underflow and hence the routine will return zero. Note that for large  $x$  the errors will be dominated by those of the Fortran intrinsic function EXP.

#### 8. Further Comments

For details of the time taken by the routine see the appropriate the Users' Note for your implementation.

#### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S18 -- Approximations of Special Functions S18ADF  
S18ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S18ADF returns the value of the modified Bessel Function  $K(x)$ ,  
1  
via the routine name.

#### 2. Specification

DOUBLE PRECISION FUNCTION S18ADF (X, IFAIL)  
INTEGER IFAIL  
DOUBLE PRECISION X

#### 3. Description

This routine evaluates an approximation to the modified Bessel Function of the second kind  $K(x)$ .

1

Note:  $K(x)$  is undefined for  $x \leq 0$  and the routine will fail for such arguments.

1

The routine is based on five Chebyshev expansions:

For  $0 < x \leq 1$ ,

$$K(x) = \frac{1}{x} \ln x + \sum_{r=0}^{\infty} \frac{a_r}{r!} T_r(t) - x \sum_{r=0}^{\infty} \frac{b_r}{r!} T_r(t), \text{ where } t = 2x - 1;$$

For  $1 < x \leq 2$ ,

$$K(x) = e^{-x} \sum_{r=0}^{\infty} \frac{c_r}{r!} T_r(t), \text{ where } t = 2x - 3;$$

For  $2 < x \leq 4$ ,

$$K(x) = e^{-x} \sum_{r=0}^{\infty} \frac{d_r}{r!} T_r(t), \text{ where } t = x - 3;$$

For  $x > 4$ ,

$$K(x) = \frac{e^{-x}}{\sqrt{x}} \sum_{r=0}^{\infty} \frac{e_r}{r!} T_r(t), \text{ where } t = \frac{9-x}{1+x}.$$

For  $x$  near zero,  $K(x) \sim \frac{1}{x}$ . This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision. For very small  $x$  on some machines, it is impossible to

1

calculate - without overflow and the routine must fail.  
 $x$

For large  $x$ , where there is a danger of underflow due to the smallness of  $K$ , the result is set exactly to zero.

1

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

1: X -- DOUBLE PRECISION Input  
 On entry: the argument  $x$  of the function. Constraint:  $X > 0$ .  
 0.

2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1  
 $X \leq 0.0$ ,  $K$  is undefined. On soft failure the routine  
 1  
 returns zero.

IFAIL= 2  
 $X$  is too small, there is a danger of overflow. On soft failure the routine returns approximately the largest representable value.

#### 7. Accuracy

Let  $(\delta)$  and  $(\epsilon)$  be the relative errors in the argument and result respectively.

If  $(\delta)$  is somewhat larger than the machine precision (i.e.,

if  $(\delta)$  is due to data errors etc), then  $(\epsilon)$  and  $(\delta)$  are approximately related by:

$$(\epsilon) \sim \frac{|xK(x) - K(x)|}{|K(x)|} (\delta).$$

Figure 1 shows the behaviour of the error amplification factor

$$\frac{|xK(x) - K(x)|}{|K(x)|}.$$

Figure 1

Please see figure in printed Reference Manual

However if  $(\delta)$  is of the same order as the machine precision, then rounding errors could make  $(\epsilon)$  slightly larger than the above relation predicts.

For small  $x$ ,  $(\epsilon) \sim (\delta)$  and there is no amplification of errors.

For large  $x$ ,  $(\epsilon) \sim x(\delta)$  and we have strong amplification of the relative error. Eventually  $K$ , which is asymptotically

$$\frac{-x}{e}$$

given by  $---$ , becomes so small that it cannot be calculated

$$\sqrt{x}$$

without underflow and hence the routine will return zero. Note that for large  $x$  the errors will be dominated by those of the Fortran intrinsic function EXP.

## 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

## 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S18 -- Approximations of Special Functions S18AEF  
 S18AEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S18AEF returns the value of the modified Bessel Function  $I_0(x)$ ,  
 via the routine name.

### 2. Specification

```
DOUBLE PRECISION FUNCTION S18AEF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

### 3. Description

This routine evaluates an approximation to the modified Bessel Function of the first kind  $I_0(x)$ .  
 0

Note:  $I_0(-x) = I_0(x)$ , so the approximation need only consider  $x \geq 0$ .  
 0 0

The routine is based on three Chebyshev expansions:

For  $0 < x \leq 4$ ,

$$I_0(x) = e^{\frac{x^2}{4}} \sum_{r=0}^{\infty} a_r T_r(t), \text{ where } t = 2\left(\frac{x}{4}\right)^2 - 1;$$

$r=0$

For  $4 < x \leq 12$ ,

$$I(x) = e^{-\frac{x}{r}} \int_0^{\frac{x}{r}} b T(t) dt, \text{ where } t = \frac{x-8}{4};$$

$r=0$

For  $x > 12$ ,

$$I(x) = \frac{e^{-\frac{x}{r}}}{\sqrt{x}} \int_0^{\frac{x}{r}} c T(t) dt, \text{ where } t = 2\left(\frac{x}{r}\right)^{-1}.$$

$r=0$

For small  $x$ ,  $I(x) \sim 1$ . This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision.

For large  $x$ , the routine must fail because of the danger of overflow in calculating  $e^{-\frac{x}{r}}$ .

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1:  $X$  -- DOUBLE PRECISION Input  
On entry: the argument  $x$  of the function.
- 2:  $IFAIL$  -- INTEGER Input/Output  
On entry:  $IFAIL$  must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
On exit:  $IFAIL = 0$  unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

X is too large. On soft failure the routine returns the approximate value of I (x) at the nearest valid argument.  
0

## 7. Accuracy

Let (delta) and (epsilon) be the relative errors in the argument and result respectively.

If (delta) is somewhat larger than the machine precision (i.e., if (delta) is due to data errors etc), then (epsilon) and (delta) are approximately related by:

$$(\epsilon) \sim \frac{|xI(x)|}{|I(x)|} (\delta).$$

Figure 1 shows the behaviour of the error amplification factor

$$\frac{|xI(x)|}{|I(x)|}$$

Figure 1

Please see figure in printed Reference Manual

However if (delta) is of the same order as machine precision, then rounding errors could make (epsilon) slightly larger than the above relation predicts.

For small x the amplification factor is approximately  $\frac{x^2}{2}$ , which implies strong attenuation of the error, but in general (epsilon) can never be less than the machine precision.

For large x,  $(\epsilon) \sim x(\delta)$  and we have strong amplification of errors. However the routine must fail for quite moderate

values of  $x$ , because  $I(x)$  would overflow; hence in practice the  
 $0$   
 loss of accuracy for large  $x$  is not excessive. Note that for  
 large  $x$  the errors will be dominated by those of the Fortran  
 intrinsic function EXP.

#### 8. Further Comments

For details of the time taken by the routine see the Users' Note  
 for your implementation.

#### 9. Example

The example program reads values of the argument  $x$  from a file,  
 evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for  
 all example programs is distributed with the NAG Foundation  
 Library software and should be available on-line.

S18 -- Approximations of Special Functions S18AFF  
 S18AFF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for  
 your implementation to check implementation-dependent details.  
 The symbol (\*) after a NAG routine name denotes a routine that is  
 not included in the Foundation Library.

#### 1. Purpose

S18AFF returns a value for the modified Bessel Function  $I(x)$ ,  
 $1$   
 via the routine name.

#### 2. Specification

```
DOUBLE PRECISION FUNCTION S18AFF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

#### 3. Description

This routine evaluates an approximation to the modified Bessel  
 Function of the first kind  $I(x)$ .

1

Note:  $I_1(-x) = -I_1(x)$ , so the approximation need only consider  $x \geq 0$

The routine is based on three Chebyshev expansions:

For  $0 < x \leq 4$ ,

$$I_1(x) = x \sum_{r=0}^{\infty} a_r T_r(t), \text{ where } t = \frac{x^2}{4} - 1;$$

For  $4 < x \leq 12$ ,

$$I_1(x) = e^{\frac{x-8}{4}} \sum_{r=0}^{\infty} b_r T_r(t), \text{ where } t = \frac{x-8}{4};$$

For  $x > 12$ ,

$$I_1(x) = \frac{e^{\frac{x}{\sqrt{x}}}}{\sqrt{x}} \sum_{r=0}^{\infty} c_r T_r(t), \text{ where } t = 2\left(\frac{x}{\sqrt{x}}\right) - 1.$$

For small  $x$ ,  $I_1(x) \sim x$ . This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision.

For large  $x$ , the routine must fail because  $I_1(x)$  cannot be represented without overflow.

#### 4. References

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S18 -- Approximations of Special Functions S18DCF  
S18DCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S18DCF returns a sequence of values for the modified Bessel functions  $K_{\nu}(z)$  for complex  $z$ , non-negative  $(\nu)$  and  $(\nu)+n$   $n=0,1,\dots,N-1$ , with an option for exponential scaling.

#### 2. Specification

```

SUBROUTINE S18DCF (FNU, Z, N, SCALE, CY, NZ, IFAIL)
 INTEGER N, NZ, IFAIL
 DOUBLE PRECISION FNU
 COMPLEX(KIND(1.0D0)) Z, CY(N)
 CHARACTER*1 SCALE

```

### 3. Description

This subroutine evaluates a sequence of values for the modified Bessel function  $K_{(\text{nu})}(z)$ , where  $z$  is complex,  $-(\pi) < \arg z \leq (\pi)$ , and  $(\text{nu})$  is the real, non-negative order. The  $N$ -member sequence is generated for orders  $(\text{nu})$ ,  $(\text{nu})+1, \dots, (\text{nu})+N-1$ .

Optionally, the sequence is scaled by the factor  $e^{\frac{z}{2}}$ .

The routine is derived from the routine CBESK in Amos [2].

Note: although the routine may not be called with  $(\text{nu})$  less than zero, for negative orders the formula  $K_{-(\text{nu})}(z) = K_{(\text{nu})}(z)$  may be used.

When  $N$  is greater than 1, extra values of  $K_{(\text{nu})}(z)$  are computed using recurrence relations.

For very large  $|z|$  or  $((\text{nu})+N-1)$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller  $|z|$  or  $((\text{nu})+N-1)$ , the computation is performed but results are accurate to less than half of machine precision. If  $|z|$  is very small, near the machine underflow threshold, or  $((\text{nu})+N-1)$  is too large, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.
- [2] Amos D E (1986) Algorithm 644: A Portable Package for Bessel Functions of a Complex Argument and Nonnegative Order. ACM Trans. Math. Softw. 12 265--273.

## 5. Parameters

- 1: FNU -- DOUBLE PRECISION Input  
 On entry: the order, (nu), of the first member of the sequence of functions. Constraint: FNU >= 0.0.
  
- 2: Z -- COMPLEX(KIND(1.0D0)) Input  
 On entry: the argument z of the functions. Constraint: Z /= (0.0, 0.0).
  
- 3: N -- INTEGER Input  
 On entry: the number, N, of members required in the sequence  
 $K_{(nu)}(z), K_{(nu)+1}(z), \dots, K_{(nu)+N-1}(z)$ . Constraint: N >= 1.
  
- 4: SCALE -- CHARACTER\*1 Input  
 On entry: the scaling option.  
  
 If SCALE = 'U', the results are returned unscaled.  
  
 If SCALE = 'S', the results are returned scaled by the  
 $z$   
 factor  $e^z$ . Constraint: SCALE = 'U' or 'S'.
  
- 5: CY(N) -- COMPLEX(KIND(1.0D)) array Output  
 On exit: the N required function values: CY(i) contains  
 $K_{(nu)+i-1}(z)$ , for  $i=1,2,\dots,N$ .
  
- 6: NZ -- INTEGER Output  
 On exit: the number of components of CY that are set to zero due to underflow. If NZ > 0 and  $\text{Re}z \geq 0.0$ , elements CY(1), CY(2), ..., CY(NZ) are set to zero. If  $\text{Re}z < 0.0$ , NZ simply states the number of underflows, and not which elements they are.
  
- 7: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry  $IFAIL = 0$  or  $-1$ , explanatory error messages are output on the current error message unit (as defined by `X04AAF`).

$IFAIL = 1$

On entry  $FNU < 0.0$ ,

or  $Z = (0.0, 0.0)$ ,

or  $N < 1$ ,

or  $SCALE \neq 'U'$  or  $'S'$ .

$IFAIL = 2$

No computation has been performed due to the likelihood of overflow, because  $ABS(Z)$  is less than a machine-dependent threshold value (given in the Users' Note for your implementation).

$IFAIL = 3$

No computation has been performed due to the likelihood of overflow, because  $FNU + N - 1$  is too large - how large depends on  $Z$  and the overflow threshold of the machine.

$IFAIL = 4$

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by `S18DCF` are accurate to less than half of machine precision. This error exit may occur if either  $ABS(Z)$  or  $FNU + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

$IFAIL = 5$

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by `S18DCF` would be lost. This error exit may occur when either  $ABS(Z)$  or  $FNU + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

$IFAIL = 6$

No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to `S18DCF` would have caused overflow or

underflow.

## 7. Accuracy

All constants in subroutine S18DCF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the maximum number of correct digits in the results obtained is limited by  $p = \min(t, 18)$ . Because of errors in argument reduction when computing elementary functions inside S18DCF, the actual number of correct digits is limited, in general, by  $p - s$ , where  $s \sim \max(1, \log_{10} |z|, \log_{10} (\nu))$  represents the number of digits

lost due to the argument reduction. Thus the larger the values of  $|z|$  and  $(\nu)$ , the less the precision in the result. If S18DCF is called with  $N > 1$ , then computation of function values via recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S18DCF with different base values of  $(\nu)$  and different  $N$ , the computed values may not agree exactly. Empirical tests with modest values of  $(\nu)$  and  $z$  have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

## 8. Further Comments

The time taken by the routine for a call of S18DCF is approximately proportional to the value of  $N$ , plus a constant. In general it is much cheaper to call S18DCF with  $N$  greater than 1, rather than to make  $N$  separate calls to S18DCF.

Paradoxically, for some values of  $z$  and  $(\nu)$ , it is cheaper to call S18DCF with a larger value of  $N$  than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different  $N$ , and the costs in each region may differ greatly.

Note that if the function required is  $K_0(x)$  or  $K_1(x)$ , i.e.,

$(\nu) = 0.0$  or  $1.0$ , where  $x$  is real and positive, and only a single function value is required, then it may be much cheaper to call S18ACF, S18ADF, S18CCF(\*) or S18CDF(\*), depending on whether a

scaled result is required or not.

### 9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the order FNU, the second is a complex value for the argument, Z, and the third is a value for the parameter SCALE. The program calls the routine with  $N = 2$  to evaluate the function for orders FNU and FNU + 1, and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S18 -- Approximations of Special Functions S18DEF  
 S18DEF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S18DEF returns a sequence of values for the modified Bessel functions  $I_{\nu}(z)$  for complex  $z$ , non-negative ( $\nu$ ) and  $(\nu)+n$   
 $n=0,1,\dots,N-1$ , with an option for exponential scaling.

### 2. Specification

```

SUBROUTINE S18DEF (FNU, Z, N, SCALE, CY, NZ, IFAIL)
 INTEGER N, NZ, IFAIL
 DOUBLE PRECISION FNU
 COMPLEX(KIND(1.0D0)) Z, CY(N)
 CHARACTER*1 SCALE

```

### 3. Description

This subroutine evaluates a sequence of values for the modified Bessel function  $I_{\nu}(z)$ , where  $z$  is complex,  $-(\pi) < \arg z \leq$

$(\pi i)$ , and  $(nu)$  is the real, non-negative order. The  $N$ -member sequence is generated for orders  $(nu)$ ,  $(nu)+1, \dots, (nu)+N-1$ .

Optionally, the sequence is scaled by the factor  $e^{-|Re(z)|}$ .

The routine is derived from the routine CBESI in Amos [2].

Note: although the routine may not be called with  $(nu)$  less than zero, for negative orders the formula

$$I_{-(nu)}(z) = I_{(nu)}(z) + \frac{2}{\pi} \sin((\pi)(nu)) K_{(nu)}(z)$$

may be used (for the Bessel function  $K_{(nu)}(z)$ , see S18DCF).

When  $N$  is greater than 1, extra values of  $I_{(nu)}(z)$  are computed using recurrence relations.

For very large  $|z|$  or  $((nu)+N-1)$ , argument reduction will cause total loss of accuracy, and so no computation is performed. For slightly smaller  $|z|$  or  $((nu)+N-1)$ , the computation is performed but results are accurate to less than half of machine precision. If  $Re(z)$  is too large and the unscaled function is required, there is a risk of overflow and so no computation is performed. In all the above cases, a warning is given by the routine.

#### 4. References

#### 5. Parameters

- 1: FNU -- DOUBLE PRECISION Input  
On entry: the order,  $(nu)$ , of the first member of the sequence of functions. Constraint: FNU  $\geq$  0.0.
- 2: Z -- COMPLEX(KIND(1.0D0)) Input  
On entry: the argument  $z$  of the functions.

- 3: N -- INTEGER Input  
 On entry: the number, N, of members required in the sequence  
 $I_{(nu)}(z), I_{(nu)+1}(z), \dots, I_{(nu)+N-1}(z)$ . Constraint:  $N \geq 1$ .
- 4: SCALE -- CHARACTER\*1 Input  
 On entry: the scaling option.  
 If SCALE = 'U', the results are returned unscaled.  
  
 If SCALE = 'S', the results are returned scaled by the  
 $-|Re z|$   
 factor  $e$  .  
 Constraint: SCALE = 'U' or 'S'.
- 5: CY(N) -- COMPLEX(KIND(1.0D)) array Output  
 On exit: the N required function values: CY(i) contains  
 $I_{(nu)+i-1}(z)$ , for  $i=1,2,\dots,N$ .
- 6: NZ -- INTEGER Output  
 On exit: the number of components of CY that are set to zero  
 due to underflow.  
  
 If  $NZ > 0$ , then elements  $CY(N-NZ+1), CY(N-NZ+2), \dots, CY(N)$  are  
 set to zero.
- 7: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not  
 familiar with this parameter (described in the Essential  
 Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see  
 Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are  
 output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry FNU < 0.0,

or  $N < 1$ ,

or SCALE /= 'U' or 'S'.

IFAIL= 2

No computation has been performed due to the likelihood of overflow, because  $\text{real}(Z)$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation). This error exit can only occur when SCALE = 'U'.

IFAIL= 3

The computation has been performed, but the errors due to argument reduction in elementary functions make it likely that the results returned by S18DEF are accurate to less than half of machine precision. This error exit may occur when either  $\text{ABS}(Z)$  or  $\text{FNU} + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 4

No computation has been performed because the errors due to argument reduction in elementary functions mean that all precision in results returned by S18DEF would be lost. This error exit may occur when either  $\text{ABS}(Z)$  or  $\text{FNU} + N - 1$  is greater than a machine-dependent threshold value (given in the Users' Note for your implementation).

IFAIL= 5

No results are returned because the algorithm termination condition has not been met. This may occur because the parameters supplied to S18DEF would have caused overflow or underflow.

## 7. Accuracy

All constants in subroutine S18DEF are given to approximately 18 digits of precision. Calling the number of digits of precision in the floating-point arithmetic being used  $t$ , then clearly the maximum number of correct digits in the results obtained is limited by  $p = \min(t, 18)$ . Because of errors in argument reduction when computing elementary functions inside S18DEF, the actual number of correct digits is limited, in general, by  $p - s$ , where  $s = \max(1, \lceil \log_{10} |z| \rceil, \lceil \log_{10} (\text{nu}) \rceil)$  represents the number of digits

lost due to the argument reduction. Thus the larger the values of  $|z|$  and  $(\text{nu})$ , the less the precision in the result. If S18DEF is called with  $N > 1$ , then computation of function values via

recurrence may lead to some further small loss of accuracy.

If function values which should nominally be identical are computed by calls to S18DEF with different base values of (nu) and different N, the computed values may not agree exactly. Empirical tests with modest values of (nu) and z have shown that the discrepancy is limited to the least significant 3-4 digits of precision.

#### 8. Further Comments

The time taken by the routine for a call of S18DEF is approximately proportional to the value of N, plus a constant. In general it is much cheaper to call S18DEF with N greater than 1, rather than to make N separate calls to S18DEF.

Paradoxically, for some values of z and (nu), it is cheaper to call S18DEF with a larger value of N than is required, and then discard the extra function values returned. However, it is not possible to state the precise circumstances in which this is likely to occur. It is due to the fact that the base value used to start recurrence may be calculated in different regions for different N, and the costs in each region may differ greatly.

Note that if the function required is  $I_0(x)$  or  $I_1(x)$ , i.e.,

(nu)=0.0 or 1.0, where x is real and positive, and only a single function value is required, then it may be much cheaper to call S18AEF, S18AFF, S18CEF(\*) or S18CFF(\*), depending on whether a scaled result is required or not.

#### 9. Example

The example program prints a caption and then proceeds to read sets of data from the input data stream. The first datum is a value for the order FNU, the second is a complex value for the argument, Z, and the third is a value for the parameter SCALE. The program calls the routine with N = 2 to evaluate the function for orders FNU and FNU + 1, and it prints the results. The process is repeated until the end of the input data stream is encountered.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S19 -- Approximations of Special Functions S19AAF  
 S19AAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S19AAF returns a value for the Kelvin function ber x via the routine name.

### 2. Specification

```
DOUBLE PRECISION FUNCTION S19AAF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

### 3. Description

This routine evaluates an approximation to the Kelvin function berx.

Note: ber(-x)=berx, so the approximation need only consider x>=0.0.

The routine is based on several Chebyshev expansions:

For 0<=x<=5,

```
--' (x)4
berx= > a T (t) with t=2(-) -1;
-- r r (5)
r=0
```

For x>5,

$$\text{berx} = \frac{e^{x/\sqrt{2}}}{\left[ \begin{pmatrix} 1 \\ x \end{pmatrix} \right]} \left[ \begin{pmatrix} 1 \\ x \end{pmatrix} \cos(\alpha) + \begin{pmatrix} 1 \\ x \end{pmatrix} \sin(\alpha) \right]$$

$$\sqrt{2(\pi)x}$$

$$\frac{e^{-x/\sqrt{2}}}{\sqrt{2(\pi)x}} \left[ \frac{(1 - c(t)) \sin(\beta) + \frac{1}{x} d(t) \cos(\beta)}{(1 - c(t)) \sin(\beta) + \frac{1}{x} d(t) \cos(\beta)} \right]$$

$$\text{where } (\alpha) = \frac{x}{8} \frac{(\pi)}{\sqrt{2}}, \quad (\beta) = \frac{x}{8} \frac{(\pi)}{\sqrt{2}},$$

and  $a(t)$ ,  $b(t)$ ,  $c(t)$ , and  $d(t)$  are expansions in the variable

$$t = \frac{10}{x}.$$

When  $x$  is sufficiently close to zero, the result is set directly to `ber 0=1.0`.

For large  $x$ , there is a danger of the result being totally inaccurate, as the error amplification factor grows in an essentially exponential manner; therefore the routine must fail.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument  $x$  of the function.
- 2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

On entry ABS(X) is too large for an accurate result to be returned. On soft failure, the routine returns zero.

#### 7. Accuracy

Since the function is oscillatory, the absolute error rather than the relative error is important. Let E be the absolute error in the result and (delta) be the relative error in the argument. If (delta) is somewhat larger than the machine precision, then we have:

$$E \sim \left| \frac{x}{\sqrt{2}} (\text{ber } x + \text{bei } x) \right| (\text{delta})$$

(provided E is within machine bounds).

For small x the error amplification is insignificant and thus the absolute error is effectively bounded by the machine precision.

For medium and large x, the error behaviour is oscillatory and

its amplitude grows like  $\frac{x}{\sqrt{2}} e^{x/\sqrt{2}}$ . Therefore it is not

possible to calculate the function with any accuracy when

$\frac{x/\sqrt{2}}{\sqrt{x e}} > \frac{1}{2(\pi)}$ . Note that this value of x is much smaller than (delta)

the minimum value of x for which the function overflows.

#### 8. Further Comments

For details of the time taken by the routine see the Users' Note for your implementation.

### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

```
S19 -- Approximations of Special Functions S19ABF
 S19ABF -- NAG Foundation Library Routine Document
```

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S19ABF returns a value for the Kelvin function  $\text{bei } x$  via the routine name.

#### 2. Specification

```
DOUBLE PRECISION FUNCTION S19ABF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

#### 3. Description

This routine evaluates an approximation to the Kelvin function  $\text{beix}$ .

Note:  $\text{bei}(-x) = \text{beix}$ , so the approximation need only consider  $x \geq 0.0$ .

The routine is based on several Chebyshev expansions:

For  $0 \leq x \leq 5$ ,

$$\text{bei } x = \sum_{r=0}^4 \frac{a_r}{r!} T_r(t), \quad \text{with } t = 2\left(\frac{x}{5}\right) - 1;$$

r=0

For  $x > 5$ ,

$$\text{bei } x = \frac{e^{x/\sqrt{2}}}{\sqrt{2(\pi)x}} \frac{\begin{bmatrix} 1 \\ (1 + a(t))\sin(\alpha) - b(t)\cos(\alpha) \end{bmatrix}}{\begin{bmatrix} 1 \\ x \end{bmatrix}}$$

$$+ \frac{e^{x/\sqrt{2}}}{\sqrt{2(\pi)x}} \frac{\begin{bmatrix} 1 \\ ((1 + c(t))\cos(\beta) - d(t)\sin(\beta)) \end{bmatrix}}{\begin{bmatrix} 1 \\ x \end{bmatrix}}$$

$$\text{where } \alpha = \frac{x}{\sqrt{2}} \frac{(\pi)}{8}, \beta = \frac{x}{\sqrt{2}} \frac{(\pi)}{8},$$

and  $a(t)$ ,  $b(t)$ ,  $c(t)$ , and  $d(t)$  are expansions in the variable

$$t = \frac{10}{x}.$$

When  $x$  is sufficiently close to zero, the result is computed as

$$\text{bei } x = \frac{x^2}{4}. \text{ If this result would underflow, the result returned is } \text{beix} = 0.0.$$

For large  $x$ , there is a danger of the result being totally inaccurate, as the error amplification factor grows in an essentially exponential manner; therefore the routine must fail.

#### 4. References

## 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument x of the function.
- 2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

On entry ABS(X) is too large for an accurate result to be returned. On soft failure, the routine returns zero.

## 7. Accuracy

Since the function is oscillatory, the absolute error rather than the relative error is important. Let E be the absolute error in the function, and (delta) be the relative error in the argument. If (delta) is somewhat larger than the machine precision, then we have:

$$E \sim \frac{x}{\sqrt{2}} |(-\operatorname{ber} x + \operatorname{bei} x)| (\delta)$$

(provided E is within machine bounds).

For small x the error amplification is insignificant and thus the absolute error is effectively bounded by the machine precision.

For medium and large x, the error behaviour is oscillatory and

its amplitude grows like  $\frac{x}{\sqrt{2\pi}} e^{x\sqrt{2}}$ . Therefore it is

impossible to calculate the functions with any accuracy when

$$\frac{x}{\sqrt{x e^{x/\sqrt{2}} / 2(\pi)}} > \text{-----}. \text{ Note that this value of } x \text{ is much smaller than } (\delta)$$

the minimum value of  $x$  for which the function overflows.

S19 -- Approximations of Special Functions S19ACF  
 S19ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S19ACF returns a value for the Kelvin function  $\ker x$ , via the routine name.

#### 2. Specification

```
DOUBLE PRECISION FUNCTION S19ACF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

#### 3. Description

This routine evaluates an approximation to the Kelvin function  $\text{ker } x$ .

Note: for  $x < 0$  the function is undefined and at  $x = 0$  it is infinite so we need only consider  $x > 0$ .

The routine is based on several Chebyshev expansions:

For  $0 < x \leq 1$ ,

$$\text{ker } x = -f(t) \log x + \frac{(\pi)^2}{16} g(t) + y(t)$$

where  $f(t)$ ,  $g(t)$  and  $y(t)$  are expansions in the variable  $t = 2x - 1$ ;

For  $1 < x \leq 3$ ,

$$\text{ker } x = \exp\left(-\frac{11}{16}x\right) q(t)$$

where  $q(t)$  is an expansion in the variable  $t = x - 2$ ;

For  $x > 3$ ,

$$\text{ker } x = \frac{(\pi)^{-x/\sqrt{2}}}{\sqrt{2x}} \frac{[(1 - c(t)) \cos(\beta) - \frac{1}{x} d(t) \sin(\beta)]}{[(1 + c(t)) \cos(\beta) + \frac{1}{x} d(t) \sin(\beta)]}$$

where  $(\beta) = \frac{x}{8} + \frac{(\pi)}{8}$ , and  $c(t)$  and  $d(t)$  are expansions in the

variable  $t = \frac{\sqrt{2}}{x} - 1$ .

When  $x$  is sufficiently close to zero, the result is computed as

$$\text{ker } x = -(\gamma) - \log\left(\frac{x}{2}\right) + \left(\frac{\pi}{8}\right) - \frac{x^2}{16} + \dots$$

and when  $x$  is even closer to zero, simply as

$$\text{ker } x = -(\gamma) - \log\left(\frac{x}{2}\right) + \dots$$

For large  $x$ ,  $\text{ker } x$  is asymptotically given by  $\frac{1}{\sqrt{2x}} e^{-(\pi/2)x}$  and

this becomes so small that it cannot be computed without underflow and the routine fails.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument  $x$  of the function. Constraint:  $X > 0$ .
- 2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

On entry  $X$  is too large, the result underflows. On soft failure, the routine returns zero.

IFAIL= 2

On entry  $X \leq 0$ , the function is undefined. On soft failure

the routine returns zero.

### 7. Accuracy

Let  $E$  be the absolute error in the result,  $(\epsilon)$  be the relative error in the result and  $(\delta)$  be the relative error in the argument. If  $(\delta)$  is somewhat larger than the machine precision, then we have:

$$E \approx \frac{x}{\sqrt{2}} \left( \frac{1}{\text{ker } x} + \frac{1}{\text{ker } x + 1} \right) (\delta),$$

$$(\epsilon) \approx \frac{\text{ker } x + 1}{x \sqrt{2}} (\delta).$$

For very small  $x$ , the relative error amplification factor is

approximately given by  $\frac{1}{|\log x|}$ , which implies a strong

attenuation of relative error. However,  $(\epsilon)$  in general cannot be less than the machine precision.

For small  $x$ , errors are damped by the function and hence are limited by the machine precision.

For medium and large  $x$ , the error behaviour, like the function itself, is oscillatory, and hence only the absolute accuracy for the function can be maintained. For this range of  $x$ , the

amplitude of the absolute error decays like  $\frac{1}{\sqrt{2}} \frac{(\pi)x^{-x/\sqrt{2}}}{2}$

which implies a strong attenuation of error. Eventually,  $\text{ker } x$ ,

which asymptotically behaves like  $\frac{1}{\sqrt{2}} \frac{(\pi)^{-x/\sqrt{2}}}{2x}$ , becomes so

small that it cannot be calculated without causing underflow, and the routine returns zero. Note that for large  $x$  the errors are dominated by those of the Fortran intrinsic function EXP.

### 8. Further Comments

Underflow may occur for a few values of  $x$  close to the zeros of  $\ker x$ , below the limit which causes a failure with IFAIL = 1.

### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S19 -- Approximations of Special Functions S19ADF  
 S19ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S19ADF returns a value for the Kelvin function  $\ker x$  via the routine name.

### 2. Specification

```
DOUBLE PRECISION FUNCTION S19ADF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

### 3. Description

This routine evaluates an approximation to the Kelvin function  $\ker x$ .

Note: for  $x < 0$  the function is undefined, so we need only consider  $x \geq 0$ .

The routine is based on several Chebyshev expansions:

For  $0 \leq x \leq 1$ ,

$$keix = -\frac{(\pi)}{4} f(t) + \frac{x^2}{4} [-g(t) \log x + v(t)]$$

where  $f(t)$ ,  $g(t)$  and  $v(t)$  are expansions in the variable  $t = 2x - 1$ ;

For  $1 < x \leq 3$ ,

$$keix = \exp\left(-\frac{(9)}{(8)} x\right) u(t)$$

where  $u(t)$  is an expansion in the variable  $t = x - 2$ ;

For  $x > 3$ ,

$$keix = \frac{1}{\sqrt{2x}} e^{-\frac{(\pi)}{2x} x} \frac{[(1 + \frac{1}{x}) c(t) \sin(\beta) + \frac{1}{x} d(t) \cos(\beta)]}{[(\frac{1}{x})]}$$

where  $(\beta) = \frac{x}{8} + \frac{(\pi)}{8}$ , and  $c(t)$  and  $d(t)$  are expansions in the

variable  $t = \frac{\sqrt{2}}{x}$ .

For  $x < 0$ , the function is undefined, and hence the routine fails and returns zero.

When  $x$  is sufficiently close to zero, the result is computed as

$$keix = -\frac{(\pi)}{2} (1 - (\gamma) - \log(-)) \frac{x^2}{2}$$

$$4 \quad ( \quad ( 2 ) ) 4$$

and when  $x$  is even closer to zero simply as

$$keix = - \frac{(\pi)}{4}.$$

For large  $x$ ,  $keix$  is asymptotically given by  $\frac{(\pi)}{2x} e^{-x/\sqrt{2}}$  and

this becomes so small that it cannot be computed without underflow and the routine fails.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument  $x$  of the function. Constraint:  $X \geq 0$ .
- 2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

IFAIL= 1

On entry  $X$  is too large, the result underflows. On soft failure, the routine returns zero.

IFAIL= 2

On entry  $X < 0$ , the function is undefined. On soft failure

the routine returns zero.

### 7. Accuracy

Let  $E$  be the absolute error in the result, and  $(\delta)$  be the relative error in the argument. If  $(\delta)$  is somewhat larger than the machine representation error, then we have:

$$E \sim \left| \frac{x}{\sqrt{2}} - \frac{(-\ker x + \text{kei } x)}{1} \right| (\delta).$$

For small  $x$ , errors are attenuated by the function and hence are limited by the machine precision.

For medium and large  $x$ , the error behaviour, like the function itself, is oscillatory and hence only absolute accuracy of the function can be maintained. For this range of  $x$ , the amplitude of

the absolute error decays like  $\frac{1}{\sqrt{2}} \frac{(\pi)x^{-x/\sqrt{2}}}{2}$ , which implies a

strong attenuation of error. Eventually,  $\text{kei } x$ , which is

asymptotically given by  $\frac{1}{\sqrt{2}} \frac{(\pi) -x/\sqrt{2}}{2x} e^{-x/\sqrt{2}}$ , becomes so small that it

cannot be calculated without causing underflow and therefore the routine returns zero. Note that for large  $x$ , the errors are dominated by those of the Fortran intrinsic function EXP.

### 8. Further Comments

Underflow may occur for a few values of  $x$  close to the zeros of  $\text{kei } x$ , below the limit which causes a failure with  $\text{IFAIL} = 1$ .

### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S20 -- Approximations of Special Functions S20ACF  
 S20ACF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S20ACF returns a value for the Fresnel Integral  $S(x)$ , via the routine name.

### 2. Specification

```
DOUBLE PRECISION FUNCTION S20ACF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

### 3. Description

This routine evaluates an approximation to the Fresnel Integral

$$S(x) = \frac{x}{\sqrt{\pi}} \int_0^x \sin\left(\frac{t^2}{2}\right) dt.$$

Note:  $S(x) = -S(-x)$ , so the approximation need only consider  $x \geq 0.0$

The routine is based on three Chebyshev expansions:

For  $0 < x \leq 3$ ,

$$S(x) = x \sum_{r=0}^3 a_r T_r(t), \quad \text{with } t = 2\left(\frac{x}{3}\right)^4 - 1;$$

For  $x > 3$ ,

$$S(x) = \frac{1}{2} \frac{f(x)}{x} \cos\left(\frac{(\pi)^2}{2} x\right) - \frac{g(x)}{3} \frac{(\pi)^2}{x} \sin\left(\frac{(\pi)^2}{2} x\right),$$

$$\text{where } f(x) = \int_{r=0}^{\infty} b_r T_r(t),$$

$$\text{and } g(x) = \int_{r=0}^{\infty} c_r T_r(t), \text{ with } t = 2\left(\frac{3}{x}\right)^{-1}.$$

For small  $x$ ,  $S(x) \sim \frac{(\pi)^3}{6} x^3$ . This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision. For very small  $x$ , this approximation would underflow; the result is then set exactly to zero.

For large  $x$ ,  $f(x) \sim \frac{1}{(\pi)^2}$  and  $g(x) \sim \frac{1}{(\pi)^2}$ . Therefore for

moderately large  $x$ , when  $\frac{1}{(\pi)^2 x^3}$  is negligible compared with  $\frac{1}{2}$ ,

the second term in the approximation for  $x > 3$  may be dropped. For very large  $x$ , when  $\frac{1}{(\pi)^2 x}$  becomes negligible,  $S(x) \sim \frac{1}{2}$ . However there will be considerable difficulties in calculating

$\cos\left(\frac{(\pi)^2}{2} x\right)$  accurately before this final limiting value can be

used. Since  $\cos\left(\frac{(\pi)^2}{2} x\right)$  is periodic, its value is essentially

determined by the fractional part of  $x^2$ . If  $x^2 = N + (\theta)$  where  $N$

is an integer and  $0 \leq (\text{theta}) < 1$ , then  $\cos\left(\frac{---x}{(2)}\right)$  depends on  $(\text{theta})$  and on  $N$  modulo 4. By exploiting this fact, it is possible to retain significance in the calculation of  $\cos\left(\frac{---x}{(2)}\right)$  either all the way to the very large  $x$  limit, or at least until the integer part of  $\frac{x}{2}$  is equal to the maximum integer allowed on the machine.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
On entry: the argument  $x$  of the function.
- 2: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL has been included for consistency with other routines in this chapter.

#### 7. Accuracy

Let  $(\delta)$  and  $(\epsilon)$  be the relative errors in the argument and result respectively.

If  $(\delta)$  is somewhat larger than the machine precision (i.e., if  $(\delta)$  is due to data errors etc), then  $(\epsilon)$  and  $(\delta)$  are approximately related by:

$$| \cos\left(\frac{---x}{(2)}\right) |$$

$$(\epsilon) \sim \frac{\left| \frac{x \sin(\frac{\pi}{2} x)}{S(x)} \right|}{\left| \frac{x \sin(\frac{\pi}{2} x)}{S(x)} \right|} (\delta).$$

Figure 1 shows the behaviour of the error amplification factor

$$\frac{\left| \frac{x \sin(\frac{\pi}{2} x)}{S(x)} \right|}{\left| \frac{x \sin(\frac{\pi}{2} x)}{S(x)} \right|}.$$

Figure 1

Please see figure in printed Reference Manual

However if  $(\delta)$  is of the same order as the machine precision, then rounding errors could make  $(\epsilon)$  slightly larger than the above relation predicts.

For small  $x$ ,  $(\epsilon) \sim 3(\delta)$  and hence there is only moderate amplification of relative error. Of course for very small  $x$  where the correct result would underflow and exact zero is returned, relative error-control is lost.

For moderately large values of  $x$ ,

$$(\epsilon) \sim \frac{\left| \frac{x \sin(\frac{\pi}{2} x)}{S(x)} \right|}{\left| \frac{x \sin(\frac{\pi}{2} x)}{S(x)} \right|} (\delta)$$

and the result will be subject to increasingly large amplification of errors. However the above relation breaks down

for large values of  $x$  (i.e., when  $\frac{1}{2}$  is of the order of the

machine precision in this region the relative error in the result is essentially bounded by  $\frac{x}{(\pi)x}$ ).

Hence the effects of error amplification are limited and at worst the relative error loss should not exceed half the possible number of significant figures.

## 8. Further Comments

None.

## 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S20 -- Approximations of Special Functions S20ADF  
 S20ADF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

S20ADF returns a value for the Fresnel Integral  $C(x)$ , via the routine name.

## 2. Specification

```
DOUBLE PRECISION FUNCTION S20ADF (X, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X
```

## 3. Description

This routine evaluates an approximation to the Fresnel Integral

$$C(x) = \frac{x}{\sqrt{\pi}} \int_0^x \cos\left(\frac{t^3}{3}\right) dt.$$

Note:  $C(x) = -C(-x)$ , so the approximation need only consider  $x \geq 0.0$

The routine is based on three Chebyshev expansions:

For  $0 < x \leq 3$ ,

$$C(x) = x + \sum_{r=0}^{\infty} a_r T_r(t), \text{ with } t = 2\left(\frac{x}{3}\right)^4 - 1;$$

For  $x > 3$ ,

$$C(x) = \frac{1}{2} \frac{f(x)}{x} \sin\left(\frac{(\pi)^2}{2} x\right) - \frac{g(x)}{3} \cos\left(\frac{(\pi)^2}{2} x\right),$$

$$\text{where } f(x) = \sum_{r=0}^{\infty} b_r T_r(t),$$

$$\text{and } g(x) = \sum_{r=0}^{\infty} c_r T_r(t), \text{ with } t = 2\left(\frac{x}{3}\right)^4 - 1.$$

For small  $x$ ,  $C(x) \sim x$ . This approximation is used when  $x$  is sufficiently small for the result to be correct to machine precision.

$$\text{For large } x, f(x) \sim \frac{1}{(\pi)^2} \text{ and } g(x) \sim \frac{1}{2(\pi)^2}. \text{ Therefore for}$$

moderately large  $x$ , when  $\frac{1}{2^3 (\pi)^2 x}$  is negligible compared with  $\frac{1}{2}$ ,

the second term in the approximation for  $x > 3$  may be dropped. For

very large  $x$ , when  $\frac{1}{(\pi)^2 x}$  becomes negligible,  $C(x) \sim \frac{1}{2}$ . However

there will be considerable difficulties in calculating

$\sin\left(\frac{(\pi)^2}{2} x\right)$  accurately before this final limiting value can be

$$\left( \frac{x^2}{2} \right)$$

$$\left( \frac{(\pi)^2}{2} \right)$$
 used. Since  $\sin\left(\frac{x^2}{2}\right)$  is periodic, its value is essentially
 
$$\left( \frac{x^2}{2} \right)$$
 determined by the fractional part of  $x^2$ . If  $x^2 = N + (\theta)$ , where  $N$ 

$$\left( \frac{(\pi)^2}{2} \right)$$
 is an integer and  $0 \leq (\theta) < 1$ , then  $\sin\left(\frac{x^2}{2}\right)$  depends on
$$\left( \frac{x^2}{2} \right)$$
 $(\theta)$  and on  $N$  modulo 4. By exploiting this fact, it is
 possible to retain some significance in the calculation of
$$\left( \frac{(\pi)^2}{2} \right)$$
 $\sin\left(\frac{x^2}{2}\right)$  either all the way to the very large  $x$  limit, or at
$$\left( \frac{x^2}{2} \right)$$
 least until the integer part of  $\frac{x^2}{2}$  is equal to the maximum
 integer allowed on the machine.

#### 4. References

- [1] Abramowitz M and Stegun I A (1968) Handbook of Mathematical Functions. Dover Publications.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input  
 On entry: the argument  $x$  of the function.
- 2: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.
- On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

There are no failure exits from this routine. The parameter IFAIL has been included for consistency with other routines in this chapter.

#### 7. Accuracy

Let  $(\delta)$  and  $(\epsilon)$  be the relative errors in the argument

and result respectively.

If  $(\delta)$  is somewhat larger than the machine precision (i.e. if  $(\delta)$  is due to data errors etc), then  $(\epsilon)$  and  $(\delta)$  are approximately related by:

$$(\epsilon) \sim \frac{(\pi)^2}{2} \frac{(\delta)}{C(x)}$$

Figure 1 shows the behaviour of the error amplification factor

$$\frac{(\pi)^2}{2} \frac{(\delta)}{C(x)}$$

Figure 1

Please see figure in printed Reference Manual

However if  $(\delta)$  is of the same order as the machine precision, then rounding errors could make  $(\epsilon)$  slightly larger than the above relation predicts.

For small  $x$ ,  $(\epsilon) \sim (\delta)$  and there is no amplification of relative error.

For moderately large values of  $x$ ,

$$(\epsilon) \sim 2 \frac{(\pi)^2}{2} \frac{(\delta)}{C(x)}$$

and the result will be subject to increasingly large amplification of errors. However the above relation breaks down

for large values of  $x$  (i.e., when  $\frac{1}{2}$  is of the order of the machine precision); in this region the relative error in the result is essentially bounded by  $\frac{x}{2}$ .

(pi)x

Hence the effects of error amplification are limited and at worst the relative error loss should not exceed half the possible number of significant figures.

#### 8. Further Comments

None.

#### 9. Example

The example program reads values of the argument  $x$  from a file, evaluates the function at each value of  $x$  and prints the results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

S21 -- Approximations of Special Functions S21BAF  
 S21BAF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

#### 1. Purpose

S21BAF returns a value of an elementary integral, which occurs as a degenerate case of an elliptic integral of the first kind, via the routine name.

#### 2. Specification

```
DOUBLE PRECISION FUNCTION S21BAF (X, Y, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X, Y
```

#### 3. Description

This routine calculates an approximate value for the integral

infty

$$R_C(x,y) = \frac{1}{2} \int_0^{\infty} \frac{dt}{\sqrt{t+x(t+y)}}$$

where  $x \geq 0$  and  $y \neq 0$ .

This function, which is related to the logarithm or inverse hyperbolic functions for  $y < x$  and to inverse circular functions if  $x < y$ , arises as a degenerate form of the elliptic integral of the first kind. If  $y < 0$ , the result computed is the Cauchy principal value of the integral.

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the system:

$$x_n = x,$$

$$0$$

$$y_n = y$$

$$0$$

$$(\mu)_n = (x_n + 2y_n)/3,$$

$$S_n = (y_n - x_n)/3(\mu)_n$$

$$(\lambda)_n = y_n + 2 \sqrt{x_n y_n}$$

$$x_{n+1} = (x_n + (\lambda)_n)/4,$$

$$y_{n+1} = (y_n + (\lambda)_n)/4.$$

The quantity  $|S_n|$  for  $n=0,1,2,3,\dots$  decreases with increasing  $n$ ,

eventually  $|S_n| \sim 1/4$ . For small enough  $S_n$  the required function value can be approximated by the first few terms of the Taylor

series about the mean. That is

$$R(x,y) = \frac{(1 + \frac{2S^2}{10n} + \frac{3S^3}{7n^2} + \frac{4S^4}{8n^3} + \frac{5S^5}{22n^4})}{C} \sqrt{\frac{1}{\mu}}$$

The truncation error involved in using this approximation is

bounded by  $\frac{16|S|^6}{n^6(1-2|S|)}$  and the recursive process is stopped when  $|S|$  is small enough for this truncation error to be negligible compared to the machine precision.

Within the domain of definition, the function value is itself representable for all representable values of its arguments. However, for values of the arguments near the extremes the above algorithm must be modified so as to avoid causing underflows or overflows in intermediate steps. In extreme regions arguments are pre-scaled away from the extremes and compensating scaling of the result is done before returning to the calling program.

#### 4. References

- [2] Carlson B C (1978) Computing Elliptic Integrals by Duplication. (Preprint) Department of Physics, Iowa State University.
- [3] Carlson B C (1988) A Table of Elliptic Integrals of the Third Kind. Math. Comput. 51 267--280.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input
- 2: Y -- DOUBLE PRECISION Input  
On entry: the arguments x and y of the function, respectively. Constraint: X >= 0.0 and Y /= 0.0.
- 3: IFAIL -- INTEGER Input/Output  
On entry: IFAIL must be set to 0, -1 or 1. For users not

familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry  $X < 0.0$ ; the function is undefined.

IFAIL= 2

On entry  $Y = 0.0$ ; the function is undefined.

On soft failure the routine returns zero.

## 7. Accuracy

In principle the routine is capable of producing full machine precision. However round-off errors in internal arithmetic will result in slight loss of accuracy. This loss should never be excessive as the algorithm does not involve any significant amplification of round-off error. It is reasonable to assume that the result is accurate to within a small multiple of the machine precision.

## 8. Further Comments

Users should consult the Chapter Introduction which shows the relationship of this function to the classical definitions of the elliptic integrals.

## 9. Example

This example program simply generates a small set of non-extreme arguments which are used with the routine to produce the table of low accuracy results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S21 -- Approximations of Special Functions S21BBF  
 S21BBF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S21BBF returns a value of the symmetrised elliptic integral of the first kind, via the routine name.

### 2. Specification

```
DOUBLE PRECISION FUNCTION S21BBF (X, Y, Z, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X, Y, Z
```

### 3. Description

This routine calculates an approximation to the integral

$$R_F(x,y,z) = \frac{1}{2} \int_0^{\infty} \frac{dt}{\sqrt{(t+x)(t+y)(t+z)}}$$

where  $x, y, z \geq 0$  and at most one is zero.

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the rule:

```
x = min(x,y,z), z = max(x,y,z),
0 0
```

```
y = remaining third intermediate value argument.
0
```

(This ordering, which is possible because of the symmetry of the function, is done for technical reasons related to the avoidance of overflow and underflow.)

$$(\mu)_n = (x_n + y_n + 3z_n)/3$$

$$X_n = (1 - x_n)/(\mu)_n$$

$$Y_n = (1 - y_n)/(\mu)_n$$

$$Z_n = (1 - z_n)/(\mu)_n$$

$$(\lambda)_n = \sqrt{x_n y_n} + \sqrt{y_n z_n} + \sqrt{z_n x_n}$$

$$x_{n+1} = (x_n + (\lambda)_n)/4$$

$$y_{n+1} = (y_n + (\lambda)_n)/4$$

$$z_{n+1} = (z_n + (\lambda)_n)/4$$

$(\epsilon)_n = \max(|X_n|, |Y_n|, |Z_n|)$  and the function may be approximated adequately by a 5th order power series:

$$R_F(x, y, z) = \frac{1}{(\mu)_n} \left( \begin{array}{c} ( \\ (E^2 + 3EE + E^2) \\ (E^2 + 2E^2 + 2E^3 + 3E^3) \\ (10 + 24 + 44 + 14) \end{array} \right)$$

where  $E^2 = X_n Y_n + Y_n Z_n + Z_n X_n$ ,  $E^3 = X_n Y_n Z_n$ .

The truncation error involved in using this approximation is bounded by  $(\epsilon)_n^6 / 4(1 - (\epsilon)_n)$  and the recursive process

is stopped when this truncation error is negligible compared with the machine precision.

Within the domain of definition, the function value is itself representable for all representable values of its arguments. However, for values of the arguments near the extremes the above algorithm must be modified so as to avoid causing underflows or overflows in intermediate steps. In extreme regions arguments are pre-scaled away from the extremes and compensating scaling of the result is done before returning to the calling program.

#### 5. Parameters

- 1: X -- DOUBLE PRECISION Input
- 2: Y -- DOUBLE PRECISION Input
- 3: Z -- DOUBLE PRECISION Input  
 On entry: the arguments x, y and z of the function.  
 Constraint: X, Y, Z  $\geq$  0.0 and only one of X, Y and Z may be zero.
- 4: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.  
  
 On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

#### 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry  $IFAIL = 0$  or  $-1$ , explanatory error messages are output on the current error message unit (as defined by  $X04AAF$ ).

$IFAIL = 1$

On entry one or more of  $X$ ,  $Y$  and  $Z$  is negative; the function is undefined.

$IFAIL = 2$

On entry two or more of  $X$ ,  $Y$  and  $Z$  are zero; the function is undefined.

On soft failure, the routine returns zero.

## 7. Accuracy

In principle the routine is capable of producing full machine precision. However round-off errors in internal arithmetic will result in slight loss of accuracy. This loss should never be excessive as the algorithm does not involve any significant amplification of round-off error. It is reasonable to assume that the result is accurate to within a small multiple of the machine precision.

## 8. Further Comments

Users should consult the Chapter Introduction which shows the relationship of this function to the classical definitions of the elliptic integrals.

If two arguments are equal, the function reduces to the elementary integral  $R$ , computed by  $S21BAF$ .

C

## 9. Example

This example program simply generates a small set of non-extreme arguments which are used with the routine to produce the table of low accuracy results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S21 -- Approximations of Special Functions

S21BCF

## S21BCF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

## 1. Purpose

S21BCF returns a value of the symmetrised elliptic integral of the second kind, via the routine name.

## 2. Specification

```
DOUBLE PRECISION FUNCTION S21BCF (X, Y, Z, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X, Y, Z
```

## 3. Description

This routine calculates an approximate value for the integral

$$R_D(x,y,z) = \frac{3}{2} \int_0^{\infty} \frac{dt}{\sqrt{(t+x)(t+y)(t+z)}}$$

where  $x, y \geq 0$ , at most one of  $x$  and  $y$  is zero, and  $z > 0$ .

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the rule:

$$\begin{aligned} x_0 &= x \\ y_0 &= y \\ z_0 &= z \\ (\mu)_n &= (x_n + y_n + 3z_n)/5 \end{aligned}$$

$$X_n = (1-x_n)/(\mu_n)$$

$$Y_n = (1-y_n)/(\mu_n)$$

$$Z_n = (1-z_n)/(\mu_n)$$

$$(\lambda)_n = \frac{1}{n} \left( \frac{x_n}{y_n} + \frac{y_n}{z_n} + \frac{z_n}{x_n} \right)$$

$$x_{n+1} = (x_n + (\lambda)_n)/4$$

$$y_{n+1} = (y_n + (\lambda)_n)/4$$

$$z_{n+1} = (z_n + (\lambda)_n)/4$$

For  $n$  sufficiently large,

$$(\epsilon)_n = \max(|X_n|, |Y_n|, |Z_n|) \sim \frac{1}{n^4} \quad (4)$$

and the function may be approximated adequately by a 5th order

$$\text{power series } R(x,y,z) = \sum_{m=0}^{\infty} \frac{(z_n + (\lambda)_n)^m}{n^m} \frac{1}{z_n}$$

$$\frac{1}{n^4} \frac{[1 + \frac{3}{7} \frac{(2)}{n} - \frac{1}{3} \frac{(3)}{n} + \frac{3}{22} \frac{(2)^2}{n} - \frac{3}{11} \frac{(4)}{n} + \frac{3}{13} \frac{(2)(3)}{n} - \frac{3}{13} \frac{(5)}{n}]}{(\mu)_n}$$

where

$$S_n^{(m)} = \frac{(X_n^m + Y_n^m + 3Z_n^m)}{2m}.$$

The truncation error in this expansion is bounded by

$$\frac{3(\epsilon)^6}{n}$$

----- and the recursive process is terminated when

$$\frac{1}{\sqrt[n]{1 - (\epsilon)^3}}$$

this quantity is negligible compared with the machine precision.

The routine may fail either because it has been called with arguments outside the domain of definition, or with arguments so extreme that there is an unavoidable danger of setting underflow or overflow.

Note:  $R(x, x, x) = x^{-3/2}$ , so there exists a region of extreme arguments for which the function value is not representable.

#### 5. Parameters

|    |                       |       |
|----|-----------------------|-------|
| 1: | X -- DOUBLE PRECISION | Input |
| 2: | Y -- DOUBLE PRECISION | Input |

3: Z -- DOUBLE PRECISION Input  
 On entry: the arguments x, y and z of the function.  
 Constraint: X, Y  $\geq$  0.0, Z > 0.0 and only one of X and Y may be zero.

4: IFAIL -- INTEGER Input/Output  
 On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry either X or Y is negative, or both X and Y are zero; the function is undefined.

IFAIL= 2

On entry Z  $\leq$  0.0; the function is undefined.

IFAIL= 3

On entry either Z is too close to zero or both X and Y are too close to zero: there is a danger of setting overflow.

IFAIL= 4

On entry at least one of X, Y and Z is too large: there is a danger of setting underflow.

On soft failure the routine returns zero.

## 7. Accuracy

In principle the routine is capable of producing full machine precision. However round-off errors in internal arithmetic will result in slight loss of accuracy. This loss should never be excessive as the algorithm does not involve any significant amplification of round-off error. It is reasonable to assume that the result is accurate to within a small multiple of the machine precision.

### 8. Further Comments

Users should consult the Chapter Introduction which shows the relationship of this function to the classical definitions of the elliptic integrals.

### 9. Example

This example program simply generates a small set of non-extreme arguments which are used with the routine to produce the table of low accuracy results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%%

S21 -- Approximations of Special Functions S21BDF  
 S21BDF -- NAG Foundation Library Routine Document

Note: Before using this routine, please read the Users' Note for your implementation to check implementation-dependent details. The symbol (\*) after a NAG routine name denotes a routine that is not included in the Foundation Library.

### 1. Purpose

S21BDF returns a value of the symmetrised elliptic integral of the third kind, via the routine name.

### 2. Specification

```
DOUBLE PRECISION FUNCTION S21BDF (X, Y, Z, R, IFAIL)
INTEGER IFAIL
DOUBLE PRECISION X, Y, Z, R
```

### 3. Description

This routine calculates an approximation to the integral

$$R(x, y, z, (\rho)) = \frac{3}{2} \int_0^{\infty} \frac{dt}{\sqrt{(t^2 + x)(t^2 + y)(t^2 + z)(t^2 + \rho)}}$$

$$0 \quad (t+(\rho)) \backslash (t+x)(t+y)(t+z)$$

where  $x, y, z \geq 0$ ,  $(\rho) \neq 0$  and at most one of  $x, y$  and  $z$  is zero.

If  $p < 0$ , the result computed is the Cauchy principal value of the integral.

The basic algorithm, which is due to Carlson [2] and [3], is to reduce the arguments recursively towards their mean by the rule:

$$\frac{x}{0} = x$$

$$\frac{y}{0} = y$$

$$\frac{z}{0} = z$$

$$\frac{(\rho)}{0} = (\rho)$$

$$\frac{(\mu)}{n} = \frac{(x + y + z + 2(\rho))}{5n}$$

$$\frac{X}{n} = \frac{(1-x)}{n(\mu)}$$

$$\frac{Y}{n} = \frac{(1-y)}{n(\mu)}$$

$$\frac{Z}{n} = \frac{(1-z)}{n(\mu)}$$

$$\frac{P}{n} = \frac{(1-(\rho))}{n(\mu)}$$

$$(\lambda) = \frac{1}{n} \sqrt{\frac{x}{y} + \frac{y}{z} + \frac{z}{x}}$$

$$\frac{x}{n+1} = \frac{(x + (\lambda))}{4n}$$

$$\frac{y}{n} = \frac{(y + (\lambda))}{4n}$$

$$\begin{aligned}
 z_{n+1} &= (z_n + (\lambda)_n) / 4 \\
 (\rho)_{n+1} &= ((\rho)_n + (\lambda)_n) / 4 \\
 (\alpha)_n &= [(\rho)_n \left( \frac{1}{x_n} + \frac{1}{y_n} + \frac{1}{z_n} \right) + \frac{1}{x_n y_n z_n}]^2 \\
 (\beta)_n &= (\rho)_n ((\rho)_n + (\lambda)_n)
 \end{aligned}$$

For  $n$  sufficiently large,

$$(\epsilon)_n = \max(|X_n|, |Y_n|, |Z_n|, |P_n|)^{\frac{1}{4}}$$

and the function may be approximated by a 5th order power series

$$\begin{aligned}
 R(x, y, z, (\rho)) &= \sum_{m=0}^{n-1} \frac{1}{m!} R((\alpha)_m, (\beta)_m) \\
 &= \frac{1}{\sqrt[n]{(\mu)_n}} \left[ 1 + \frac{3}{7} \frac{S^{(2)}}{n} + \frac{1}{3} \frac{S^{(3)}}{n} + \frac{3}{22} \frac{S^{(2)^2}}{n} + \frac{3}{11} \frac{S^{(4)}}{n} + \frac{3}{13} \frac{S^{(2)} S^{(3)}}{n} + \frac{3}{13} \frac{S^{(5)}}{n} \right] \\
 \text{where } S^{(m)}_n &= (X_n^m + Y_n^m + Z_n^m + 2P_n^m) / 2m.
 \end{aligned}$$

The truncation error in this expansion is bounded by

$$\frac{3(\epsilon)^{6/n}}{(1-\epsilon)^{3/n}}$$
 and the recursion process is terminated when this quantity is negligible compared with the machine precision. The routine may fail either because it has been called with arguments outside the domain of definition or with arguments so extreme that there is an unavoidable danger of setting underflow or overflow.

$$-\frac{3}{2}$$

Note:  $R(x, x, x, x) = x$ , so there exists a region of extreme arguments for which the function value is not representable.

| 4: | R -- DOUBLE PRECISION                                                                                                                                       | Input        |
|    | On entry: the arguments x, y, z and (rho) of the function.                                                                                                  |              |
|    | Constraint: X, Y, Z >= 0.0, R /= 0.0 and at most one of X, Y and Z may be zero.                                                                             |              |
| 5: | IFAIL -- INTEGER                                                                                                                                            | Input/Output |
|    | On entry: IFAIL must be set to 0, -1 or 1. For users not familiar with this parameter (described in the Essential Introduction) the recommended value is 0. |              |

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

## 6. Error Indicators and Warnings

Errors detected by the routine:

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

IFAIL= 1

On entry at least one of X, Y and Z is negative, or at least two of them are zero; the function is undefined.

IFAIL= 2

On entry R = 0.0; the function is undefined.

IFAIL= 3

On entry either R is too close to zero, or any two of X, Y and Z are too close to zero; there is a danger of setting overflow.

IFAIL= 4

On entry at least one of X, Y, Z and R is too large; there is a danger of setting underflow.

IFAIL= 5

An error has occurred in a call to S21BAF. Any such occurrence should be reported to NAG.

On soft failure, the routine returns zero.

## 7. Accuracy

In principle the routine is capable of producing full machine precision. However round-off errors in internal arithmetic will result in slight loss of accuracy. This loss should never be excessive as the algorithm does not involve any significant amplification of round-off error. It is reasonable to assume that the result is accurate to within a small multiple of the machine precision.

## 8. Further Comments

Users should consult the Chapter Introduction which shows the

relationship of this function to the classical definitions of the elliptic integrals.

If the argument  $R$  is equal to any of the other arguments, the function reduces to the integral  $R$ , computed by S21BCF.

D

#### 9. Example

This example program simply generates a small set of non-extreme arguments which are used with the routine to produce the table of low accuracy results.

The example program is not reproduced here. The source code for all example programs is distributed with the NAG Foundation Library software and should be available on-line.

```

s0leaf : (Complex DoubleFloat,Integer) -> Result
++ s0leaf(z,ifail)
++ S01EAF evaluates the exponential function exp(z) , for complex z.
++ See \downlink{Manual Page}{manpageXXs01eaf}.
s13aaf : (DoubleFloat,Integer) -> Result
++ s13aaf(x,ifail)
++ returns the value of the exponential integral
++ E (x), via the routine name.
++ 1
++ See \downlink{Manual Page}{manpageXXs13aaf}.

```

```

s13acf : (DoubleFloat,Integer) -> Result
++ s13acf(x,ifail)
++ returns the value of the cosine integral
++ See \downlink{Manual Page}{manpageXXs13acf}.
s13adf : (DoubleFloat,Integer) -> Result
++ s13adf(x,ifail)
++ returns the value of the sine integral
++ See \downlink{Manual Page}{manpageXXs13adf}.
s14aaf : (DoubleFloat,Integer) -> Result
++ s14aaf(x,ifail) returns the value of the Gamma function $(\Gamma)(x)$, via
++ the routine name.
++ See \downlink{Manual Page}{manpageXXs14aaf}.
s14abf : (DoubleFloat,Integer) -> Result
++ s14abf(x,ifail) returns a value for the log, $\ln(\Gamma(x))$, via
++ the routine name.
++ See \downlink{Manual Page}{manpageXXs14abf}.
s14baf : (DoubleFloat,DoubleFloat,DoubleFloat,Integer) -> Result
++ s14baf(a,x,tol,ifail)
++ computes values for the incomplete gamma functions $P(a,x)$
++ and $Q(a,x)$.
++ See \downlink{Manual Page}{manpageXXs14baf}.
s15adf : (DoubleFloat,Integer) -> Result
++ s15adf(x,ifail)
++ returns the value of the complementary error function,
++ $\operatorname{erfc}(x)$, via the routine name.
++ See \downlink{Manual Page}{manpageXXs15adf}.
s15aef : (DoubleFloat,Integer) -> Result
++ s15aef(x,ifail)
++ returns the value of the error function $\operatorname{erf}(x)$, via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs15aef}.
s17acf : (DoubleFloat,Integer) -> Result
++ s17acf(x,ifail)
++ returns the value of the Bessel Function
++ $Y_0(x)$, via the routine name.
++ 0
++ See \downlink{Manual Page}{manpageXXs17acf}.
s17adf : (DoubleFloat,Integer) -> Result
++ s17adf(x,ifail)
++ returns the value of the Bessel Function
++ $Y_1(x)$, via the routine name.
++ 1
++ See \downlink{Manual Page}{manpageXXs17adf}.
s17aef : (DoubleFloat,Integer) -> Result
++ s17aef(x,ifail)
++ returns the value of the Bessel Function

```

```

++ J (x), via the routine name.
++ 0
++ See \downlink{Manual Page}{manpageXXs17aef}.
s17aff : (DoubleFloat,Integer) -> Result
++ s17aff(x,ifail)
++ returns the value of the Bessel Function
++ J (x), via the routine name.
++ 1
++ See \downlink{Manual Page}{manpageXXs17aff}.
s17agf : (DoubleFloat,Integer) -> Result
++ s17agf(x,ifail)
++ returns a value for the Airy function, Ai(x), via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs17agf}.
s17ahf : (DoubleFloat,Integer) -> Result
++ s17ahf(x,ifail)
++ returns a value of the Airy function, Bi(x), via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs17ahf}.
s17ajf : (DoubleFloat,Integer) -> Result
++ s17ajf(x,ifail)
++ returns a value of the derivative of the Airy function
++ Ai(x), via the routine name.
++ See \downlink{Manual Page}{manpageXXs17ajf}.
s17akf : (DoubleFloat,Integer) -> Result
++ s17akf(x,ifail)
++ returns a value for the derivative of the Airy function
++ Bi(x), via the routine name.
++ See \downlink{Manual Page}{manpageXXs17akf}.
s17dcf : (DoubleFloat,Complex DoubleFloat,Integer,String,
Integer) -> Result
++ s17dcf(fnu,z,n,scale,ifail)
++ returns a sequence of values for the Bessel functions
++ Y (z) for complex z, non-negative (nu) and n=0,1,...,N-1,
++ (nu)+n
++ with an option for exponential scaling.
++ See \downlink{Manual Page}{manpageXXs17dcf}.
s17def : (DoubleFloat,Complex DoubleFloat,Integer,String,
Integer) -> Result
++ s17def(fnu,z,n,scale,ifail)
++ returns a sequence of values for the Bessel functions
++ J (z) for complex z, non-negative (nu) and n=0,1,...,N-1,
++ (nu)+n
++ with an option for exponential scaling.
++ See \downlink{Manual Page}{manpageXXs17def}.
s17dgm : (String,Complex DoubleFloat,String,Integer) -> Result

```

```

++ s17dgf(deriv,z,scale,ifail)
++ returns the value of the Airy function Ai(z) or its
++ derivative Ai'(z) for complex z, with an option for exponential
++ scaling.
++ See \downlink{Manual Page}{manpageXXs17dgf}.
s17dhf : (String,Complex DoubleFloat,String,Integer) -> Result
++ s17dhf(deriv,z,scale,ifail)
++ returns the value of the Airy function Bi(z) or its
++ derivative Bi'(z) for complex z, with an option for exponential
++ scaling.
++ See \downlink{Manual Page}{manpageXXs17dhf}.
s17dlf : (Integer,DoubleFloat,Complex DoubleFloat,Integer,_
String,Integer) -> Result
++ s17dlf(m,fnu,z,n,scale,ifail)
++ returns a sequence of values for the Hankel functions
++ (1) (2)
++ H (z) or H (z) for complex z, non-negative (nu) and
++ (nu)+n (nu)+n
++ n=0,1,...,N-1, with an option for exponential scaling.
++ See \downlink{Manual Page}{manpageXXs17dlf}.
s18acf : (DoubleFloat,Integer) -> Result
++ s18acf(x,ifail)
++ returns the value of the modified Bessel Function
++ K (x), via the routine name.
++ 0
++ See \downlink{Manual Page}{manpageXXs18acf}.
s18adf : (DoubleFloat,Integer) -> Result
++ s18adf(x,ifail)
++ returns the value of the modified Bessel Function
++ K (x), via the routine name.
++ 1
++ See \downlink{Manual Page}{manpageXXs18adf}.
s18aef : (DoubleFloat,Integer) -> Result
++ s18aef(x,ifail)
++ returns the value of the modified Bessel Function
++ I (x), via the routine name.
++ 0
++ See \downlink{Manual Page}{manpageXXs18aef}.
s18aff : (DoubleFloat,Integer) -> Result
++ s18aff(x,ifail)
++ returns a value for the modified Bessel Function
++ I (x), via the routine name.
++ 1
++ See \downlink{Manual Page}{manpageXXs18aff}.
s18dcf : (DoubleFloat,Complex DoubleFloat,Integer,String,_
Integer) -> Result

```

```

++ s18dcf(fnu,z,n,scale,ifail)
++ returns a sequence of values for the modified Bessel functions
++ $K_{\nu}(z)$ for complex z , non-negative (ν) and
++ $(\nu)+n$
++ $n=0,1,\dots,N-1$, with an option for exponential scaling.
++ See \downlink{Manual Page}{manpageXXs18dcf}.
s18def : (DoubleFloat,Complex DoubleFloat,Integer,String,
Integer) -> Result
++ s18def(fnu,z,n,scale,ifail)
++ returns a sequence of values for the modified Bessel functions
++ $I_{\nu}(z)$ for complex z , non-negative (ν) and
++ $(\nu)+n$
++ $n=0,1,\dots,N-1$, with an option for exponential scaling.
++ See \downlink{Manual Page}{manpageXXs18def}.
s19aaf : (DoubleFloat,Integer) -> Result
++ s19aaf(x,ifail)
++ returns a value for the Kelvin function $\text{ber}(x)$ via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs19aaf}.
s19abf : (DoubleFloat,Integer) -> Result
++ s19abf(x,ifail)
++ returns a value for the Kelvin function $\text{bei}(x)$ via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs19abf}.
s19acf : (DoubleFloat,Integer) -> Result
++ s19acf(x,ifail)
++ returns a value for the Kelvin function $\text{ker}(x)$, via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs19acf}.
s19adf : (DoubleFloat,Integer) -> Result
++ s19adf(x,ifail)
++ returns a value for the Kelvin function $\text{kei}(x)$ via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs19adf}.
s20acf : (DoubleFloat,Integer) -> Result
++ s20acf(x,ifail)
++ returns a value for the Fresnel Integral $S(x)$, via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs20acf}.
s20adf : (DoubleFloat,Integer) -> Result
++ s20adf(x,ifail)
++ returns a value for the Fresnel Integral $C(x)$, via the
++ routine name.
++ See \downlink{Manual Page}{manpageXXs20adf}.
s21baf : (DoubleFloat,DoubleFloat,Integer) -> Result
++ s21baf(x,y,ifail)

```

```

++ returns a value of an elementary integral, which occurs as
++ a degenerate case of an elliptic integral of the first kind, via
++ the routine name.
++ See \downlink{Manual Page}{manpageXXs21baf}.
s21bbf : (DoubleFloat,DoubleFloat,DoubleFloat,Integer) -> Result
++ s21bbf(x,y,z,ifail)
++ returns a value of the symmetrised elliptic integral of
++ the first kind, via the routine name.
++ See \downlink{Manual Page}{manpageXXs21bbf}.
s21bcf : (DoubleFloat,DoubleFloat,DoubleFloat,Integer) -> Result
++ s21bcf(x,y,z,ifail)
++ returns a value of the symmetrised elliptic integral of
++ the second kind, via the routine name.
++ See \downlink{Manual Page}{manpageXXs21bcf}.
s21bdf : (DoubleFloat,DoubleFloat,DoubleFloat,DoubleFloat,_
Integer) -> Result
++ s21bdf(x,y,z,r,ifail)
++ returns a value of the symmetrised elliptic integral of
++ the third kind, via the routine name.
++ See \downlink{Manual Page}{manpageXXs21bdf}.

++ References:

++ Description:

++ In this package F is a framed algebra over the integers (typically  
 ++  $\mathbb{Z}[a]$  for some algebraic integer a). The package provides  
 ++ functions to compute the integral closure of  $\mathbb{Z}$  in the quotient  
 ++ quotient field of F.

NumberFieldIntegralBasis(UP,F): Exports == Implementation where

UP : UnivariatePolynomialCategory Integer

F : FramedAlgebra(Integer,UP)

FR ==> Factored Integer

I ==> Integer

Mat ==> Matrix I

NNI ==> NonNegativeInteger

Ans ==> Record(basis: Mat, basisDen: I, basisInv:Mat,discr: I)

```

Exports ==> with
discriminant: () -> Integer
 ++ \spad{discriminant()} returns the discriminant of the integral
 ++ closure of Z in the quotient field of the framed algebra F.
integralBasis : () -> Record(basis: Mat, basisDen: I, basisInv:Mat)
 ++ \spad{integralBasis()} returns a record
 ++ \spad{[basis,basisDen,basisInv]}
 ++ containing information regarding the integral closure of Z in the
 ++ quotient field of F, where F is a framed algebra with Z-module
 ++ basis \spad{w1,w2,...,wn}.
 ++ If \spad{basis} is the matrix \spad{(aij, i = 1..n, j = 1..n)}, then
 ++ the \spad{i}th element of the integral basis is
 ++ \spad{vi = (1/basisDen) * sum(aij * wj, j = 1..n)}, i.e. the
 ++ \spad{i}th row of \spad{basis} contains the coordinates of the
 ++ \spad{i}th basis vector. Similarly, the \spad{i}th row of the
 ++ matrix \spad{basisInv} contains the coordinates of \spad{wi} with
 ++ respect to the basis \spad{v1,...,vn}: if \spad{basisInv} is the
 ++ matrix \spad{(bij, i = 1..n, j = 1..n)}, then
 ++ \spad{wi = sum(bij * vj, j = 1..n)}.
localIntegralBasis : I -> Record(basis: Mat, basisDen: I, basisInv:Mat)
 ++ \spad{integralBasis(p)} returns a record
 ++ \spad{[basis,basisDen,basisInv]} containing information regarding
 ++ the local integral closure of Z at the prime \spad{p} in the quotient
 ++ field of F, where F is a framed algebra with Z-module basis
 ++ \spad{w1,w2,...,wn}.
 ++ If \spad{basis} is the matrix \spad{(aij, i = 1..n, j = 1..n)}, then
 ++ the \spad{i}th element of the integral basis is

*++ Keywords:*

*++ References:*

*++ Description:*

*++ This package is a suite of functions for the numerical integration of an  
++ ordinary differential equation of n variables:*

*++*

*++           \center{dy/dx = f(y,x)\space{5}y is an n-vector}*

*++*

*++ \par All the routines are based on a 4-th order Runge-Kutta kernel.*

*++ These routines generally have as arguments:*

*++ n, the number of dependent variables;*

*++ x1, the initial point;*

*++ h, the step size;*

*++ y, a vector of initial conditions of length n which upon exit contains the sol*

*++ \spad{derivs}, a function which computes the right hand side of the*

*++ ordinary differential equation: \spad{derivs(dydx,y,x)} computes \spad{dydx},*

*++ a vector which contains the derivative information.*

*++*

```

++ \par In order of increasing complexity:\begin{items}
++
++ \item \spad{rk4(y,n,x1,h,derivs)} advances the solution vector to
++ \spad{x1 + h} and return the values in y.
++
++ \item \spad{rk4(y,n,x1,h,derivs,t1,t2,t3,t4)} is the same as
++ \spad{rk4(y,n,x1,h,derivs)} except that you must provide 4 scratch
++ arrays t1-t4 of size n.
++
++ \item Starting with y at x1, \spad{rk4f(y,n,x1,x2,ns,derivs)}
++ uses \spad{ns} fixed
++ steps of a 4-th order Runge-Kutta integrator to advance the
++ solution vector to x2 and return the values in y.
++ Argument x2, is the final point, and
++ \spad{ns}, the number of steps to take.
++
++ \item \spad{rk4qc(y,n,x1,step,eps,yscal,derivs)} takes a 5-th order
++ Runge-Kutta step with monitoring
++ of local truncation to ensure accuracy and adjust stepsize.
++ The function takes two half steps and one full step and scales
++ the difference in solutions at the final point. If the error is
++ within \spad{eps}, the step is taken and the result is returned.
++ If the error is not within \spad{eps}, the stepsize is decreased
++ and the procedure is tried again until the desired accuracy is
++ reached. Upon input, an trial step size must be given and upon
++ return, an estimate of the next step size to use is returned as
++ well as the step size which produced the desired accuracy.
++ The scaled error is computed as
++ \center{\spad{error = MAX(ABS((y2steps(i) - y1step(i))/yscal(i))))}
++ and this is compared against \spad{eps}. If this is greater
++ than \spad{eps}, the step size is reduced accordingly to
++ \center{\spad{hnew = 0.9 * hdid * (error/eps)**(-1/4)}}
++ If the error criterion is satisfied, then we check if the
++ step size was too fine and return a more efficient one. If
++ \spad{error > \spad{eps} * (6.0E-04)} then the next step size should be
++ \center{\spad{hnext = 0.9 * hdid * (error/\spad{eps})**(-1/5)}}
++ Otherwise \spad{hnext = 4.0 * hdid} is returned.
++ A more detailed discussion of this and related topics can be
++ found in the book "Numerical Recipies" by W.Press, B.P. Flannery,
++ S.A. Teukolsky, W.T. Vetterling published by Cambridge University Press.
++ Argument \spad{step} is a record of 3 floating point
++ numbers \spad{(try , did , next)},
++ \spad{eps} is the required accuracy,
++ \spad{yscal} is the scaling vector for the difference in solutions.
++ On input, \spad{step.try} should be the guess at a step
++ size to achieve the accuracy.

```

```

++ On output, \spad{step.did} contains the step size which achieved the
++ accuracy and \spad{step.next} is the next step size to use.
++
++ \item \spad{rk4qc(y,n,x1,step,eps,yscal,derivs,t1,t2,t3,t4,t5,t6,t7)} is the
++ same as \spad{rk4qc(y,n,x1,step,eps,yscal,derivs)} except that the user
++ must provide the 7 scratch arrays \spad{t1-t7} of size n.
++
++ \item \spad{rk4a(y,n,x1,x2,eps,h,ns,derivs)}
++ is a driver program which uses \spad{rk4qc} to integrate n ordinary
++ differential equations starting at x1 to x2, keeping the local
++ truncation error to within \spad{eps} by changing the local step size.
++ The scaling vector is defined as
++ \center{\spad{yscal(i) = abs(y(i)) + abs(h*dydx(i)) + tiny}}
++ where \spad{y(i)} is the solution at location x, \spad{dydx} is the
++ ordinary differential equation's right hand side, h is the current
++ step size and \spad{tiny} is 10 times the
++ smallest positive number representable.
++ The user must supply an estimate for a trial step size and
++ the maximum number of calls to \spad{rk4qc} to use.
++ Argument x2 is the final point,
++ \spad{eps} is local truncation,
++ \spad{ns} is the maximum number of call to \spad{rk4qc} to use.
++ \end{items}

++ Author: Yuriy A. Baransky
++ Date Created: October 90
++ Date Last Updated: October 90
++ Basic Operations:
++ Related Constructors:
++ Also See:
++ AMS Classifications:
++ Keywords:
++ References:
++ Description:
++ This suite of routines performs numerical quadrature using
++ algorithms derived from the basic trapezoidal rule. Because
++ the error term of this rule contains only even powers of the
++ step size (for open and closed versions), fast convergence
++ can be obtained if the integrand is sufficiently smooth.
++
++ Each routine returns a Record of type TrapAns, which contains\indent{3}
++ \newline value (\spadtype{Float}):\tab{20} estimate of the integral
++ \newline error (\spadtype{Float}):\tab{20} estimate of the error in the computation
++ \newline totalpts (\spadtype{Integer}):\tab{20} total number of function evaluations
++ \newline success (\spadtype{Boolean}):\tab{20} if the integral was computed within the us
++ \indent{0}\indent{0}
++ To produce this estimate, each routine generates an internal
++ sequence of sub-estimates, denoted by {\em S(i)}, depending on the
```

```

++ routine, to which the various convergence criteria are applied.
++ The user must supply a relative accuracy, \spad{eps_r}, and an absolute
++ accuracy, \spad{eps_a}. Convergence is obtained when either
++ \center{\spad{ABS(S(i) - S(i-1)) < eps_r * ABS(S(i-1))}}
++ \center{or \spad{ABS(S(i) - S(i-1)) < eps_a}}
++ are true statements.
++
++ The routines come in three families and three flavors:
++ \newline\tab{3} closed:\tab{20}romberg,\tab{30}simpson,\tab{42}trapezoidal
++ \newline\tab{3} open: \tab{20}rombergo,\tab{30}simpsono,\tab{42}trapezoidal
++ \newline\tab{3} adaptive closed:\tab{20}aromberg,\tab{30}asimpson,\tab{42}atra
++ \par
++ The {\em S(i)} for the trapezoidal family is the value of the
++ integral using an equally spaced abscissa trapezoidal rule for
++ that level of refinement.
++ \par
++ The {\em S(i)} for the simpson family is the value of the integral
++ using an equally spaced abscissa simpson rule for that level of
++ refinement.
++ \par
++ The {\em S(i)} for the romberg family is the estimate of the integral
++ using an equally spaced abscissa romberg method. For
++ the \spad{i}-th level, this is an appropriate combination of all the
++ previous trapezoidal estimates so that the error term starts
++ with the \spad{2*(i+1)} power only.
++ \par
++ The three families come in a closed version, where the formulas
++ include the endpoints, an open version where the formulas do not
++ include the endpoints and an adaptive version, where the user
++ is required to input the number of subintervals over which the
++ appropriate closed family integrator will apply with the usual
++ convergence parameters for each subinterval. This is useful
++ where a large number of points are needed only in a small fraction
++ of the entire domain.
++ \par
++ Each routine takes as arguments:
++ \newline f\tab{10} integrand
++ \newline a\tab{10} starting point
++ \newline b\tab{10} ending point
++ \newline \spad{eps_r}\tab{10} relative error
++ \newline \spad{eps_a}\tab{10} absolute error
++ \newline \spad{nmin} \tab{10} refinement level when to start checking for conv
++ \newline \spad{nmax} \tab{10} maximum level of refinement
++ \par
++ The adaptive routines take as an additional parameter
++ \newline \spad{nint}\tab{10} the number of independent intervals to apply a cl

```

```

++ family integrator of the same name.
++ \par Notes:
++ \newline Closed family level i uses \spad{1 + 2**i} points.
++ \newline Open family level i uses \spad{1 + 3**i} points.

 aroberg : (F -> F,F,F,F,F,I,I,I) -> TrapAns
 ++ aroberg(fn,a,b,epsrel,epsabs,nmin,nmax,nint)
 ++ uses the adaptive romberg method to numerically integrate function
 ++ \spad{fn} over the closed interval from \spad{a} to \spad{b},
 ++ with relative accuracy \spad{epsrel} and absolute accuracy
 ++ \spad{epsabs}, with the refinement levels for convergence checking
 ++ vary from \spad{nmin} to \spad{nmax}, and where \spad{nint}
 ++ is the number of independent intervals to apply the integrator.
 ++ The value returned is a record containing the value of the integral,
 ++ the estimate of the error in the computation, the total number of
 ++ function evaluations, and either a boolean value which is true if
 ++ the integral was computed within the user specified error criterion.
 ++ See \spadtype{NumericalQuadrature} for details.
 asimpson : (F -> F,F,F,F,F,I,I,I) -> TrapAns
 ++ asimpson(fn,a,b,epsrel,epsabs,nmin,nmax,nint) uses the
 ++ adaptive simpson method to numerically integrate function \spad{fn}
 ++ over the closed interval from \spad{a} to \spad{b}, with relative
 ++ accuracy \spad{epsrel} and absolute accuracy \spad{epsabs}, with the
 ++ refinement levels for convergence checking vary from \spad{nmin}
 ++ to \spad{nmax}, and where \spad{nint} is the number of independent
 ++ intervals to apply the integrator. The value returned is a record
 ++ containing the value of the integral, the estimate of the error in
 ++ the computation, the total number of function evaluations, and
 ++ either a boolean value which is true if the integral was computed
 ++ within the user specified error criterion.
 ++ See \spadtype{NumericalQuadrature} for details.
 atrapezoidal : (F -> F,F,F,F,F,I,I,I) -> TrapAns
 ++ atrapezoidal(fn,a,b,epsrel,epsabs,nmin,nmax,nint) uses the
 ++ adaptive trapezoidal method to numerically integrate function
 ++ \spad{fn} over the closed interval from \spad{a} to \spad{b}, with

```

```

++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
++ with the refinement levels for convergence checking vary from
++ \spad{nmin} to \spad{nmax}, and where \spad{nint} is the number
++ of independent intervals to apply the integrator. The value returned
++ is a record containing the value of the integral, the estimate of
++ the error in the computation, the total number of function
++ evaluations, and either a boolean value which is true if
++ the integral was computed within the user specified error criterion.
++ See \spadtype{NumericalQuadrature} for details.
romberg : (F -> F,F,F,F,F,I,I) -> TrapAns
++ romberg(fn,a,b,epsrel,epsabs,nmin,nmax) uses the romberg
++ method to numerically integrate function \spadvar{fn} over the closed
++ interval \spad{a} to \spad{b}, with relative accuracy \spad{epsrel}
++ and absolute accuracy \spad{epsabs}, with the refinement levels
++ for convergence checking vary from \spad{nmin} to \spad{nmax}.
++ The value returned is a record containing the value
++ of the integral, the estimate of the error in the computation, the
++ total number of function evaluations, and either a boolean value
++ which is true if the integral was computed within the user specified
++ error criterion. See \spadtype{NumericalQuadrature} for details.
simpson : (F -> F,F,F,F,F,I,I) -> TrapAns
++ simpson(fn,a,b,epsrel,epsabs,nmin,nmax) uses the simpson
++ method to numerically integrate function \spad{fn} over the closed
++ interval \spad{a} to \spad{b}, with
++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
++ with the refinement levels for convergence checking vary from
++ \spad{nmin} to \spad{nmax}. The value returned
++ is a record containing the value of the integral, the estimate of
++ the error in the computation, the total number of function
++ evaluations, and either a boolean value which is true if
++ the integral was computed within the user specified error criterion.
++ See \spadtype{NumericalQuadrature} for details.
trapezoidal : (F -> F,F,F,F,F,I,I) -> TrapAns
++ trapezoidal(fn,a,b,epsrel,epsabs,nmin,nmax) uses the
++ trapezoidal method to numerically integrate function \spadvar{fn} over
++ the closed interval \spad{a} to \spad{b}, with relative accuracy
++ \spad{epsrel} and absolute accuracy \spad{epsabs}, with the
++ refinement levels for convergence checking vary
++ from \spad{nmin} to \spad{nmax}. The value
++ returned is a record containing the value of the integral, the
++ estimate of the error in the computation, the total number of
++ function evaluations, and either a boolean value which is true
++ if the integral was computed within the user specified error criterion.
++ See \spadtype{NumericalQuadrature} for details.
rombergo : (F -> F,F,F,F,F,I,I) -> TrapAns
++ rombergo(fn,a,b,epsrel,epsabs,nmin,nmax) uses the romberg

```

```

++ method to numerically integrate function \spad{fn} over
++ the open interval from \spad{a} to \spad{b}, with
++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
++ with the refinement levels for convergence checking vary from
++ \spad{nmin} to \spad{nmax}. The value returned
++ is a record containing the value of the integral, the estimate of
++ the error in the computation, the total number of function
++ evaluations, and either a boolean value which is true if
++ the integral was computed within the user specified error criterion.
++ See \spadtype{NumericalQuadrature} for details.
simpsono : (F -> F,F,F,F,F,I,I) -> TrapAns
++ simpsono(fn,a,b,epsrel,epsabs,nmin,nmax) uses the
++ simpson method to numerically integrate function \spad{fn} over
++ the open interval from \spad{a} to \spad{b}, with
++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
++ with the refinement levels for convergence checking vary from
++ \spad{nmin} to \spad{nmax}. The value returned
++ is a record containing the value of the integral, the estimate of
++ the error in the computation, the total number of function
++ evaluations, and either a boolean value which is true if
++ the integral was computed within the user specified error criterion.
++ See \spadtype{NumericalQuadrature} for details.
trapezoidal : (F -> F,F,F,F,F,I,I) -> TrapAns
++ trapezoidal(fn,a,b,epsrel,epsabs,nmin,nmax) uses the
++ trapezoidal method to numerically integrate function \spad{fn}
++ over the open interval from \spad{a} to \spad{b}, with
++ relative accuracy \spad{epsrel} and absolute accuracy \spad{epsabs},
++ with the refinement levels for convergence checking vary from
++ \spad{nmin} to \spad{nmax}. The value returned
++ is a record containing the value of the integral, the estimate of
++ the error in the computation, the total number of function
++ evaluations, and either a boolean value which is true if
++ the integral was computed within the user specified error criterion.
++ See \spadtype{NumericalQuadrature} for details.

++ Description:
++ In this package K is a finite field, R is a ring of univariate
++ polynomials over K, and F is a monogenic algebra over R.
++ We require that F is monogenic, i.e. that \spad{F = K[x,y]/(f(x,y))},
++ because the integral basis algorithm used will factor the polynomial
++ \spad{f(x,y)}. The package provides a function to compute the integral
++ closure of R in the quotient field of F as well as a function to compute
++ a "local integral basis" at a specific prime.

++ This package completely solves a parametric linear system of equations
++ by decomposing the set of all parametric values for which the linear
++ system is consistent into a union of quasi-algebraic sets (which need
++ not be irredundant, but most of the time is). Each quasi-algebraic
++ set is described by a list of polynomials that vanish on the set, and
++ a list of polynomials that vanish at no point of the set.
++ For each quasi-algebraic set, the solution of the linear system
++ is given, as a particular solution and a basis of the homogeneous
++ system.
++ The parametric linear system should be given in matrix form, with
++ a coefficient matrix and a right hand side vector. The entries
++ of the coefficient matrix and right hand side vector should be
++ polynomials in the parametric variables, over a Euclidean domain
++ of characteristic zero.
++
++ If the system is homogeneous, the right hand side need not be given.
++ The right hand side can also be replaced by an indeterminate vector,
++ in which case, the conditions required for consistency will also be
++ given.
++
++ The package has other facilities for saving results to external
++ files, as well as solving the system for a specified minimum rank.
++ Altogether there are 12 mode maps for psolve, as explained below.

```

```

-- modified to conform with new runtime system 06/04/90
-- updated with comments for MB, 02/16/94
-- also cleaned up some unnecessary arguments in regime routine
--
-- MB: In order to allow the rhs to be indeterminate, while working
-- mainly with the parametric variables on the lhs (less number of
-- variables), certain conversions of internal representation from
-- GR to Polynomial R and Fraction Polynomial R are done. At the time
-- of implementation, I thought that this may be more efficient. I
-- have not done any comparison since that requires rewriting the
-- package. My own application needs to call this package quite often,
-- and most computations involves only polynomials in the parametric
-- variables.

-- The 12 modes of psolve are probably not all necessary. Again, I
-- was thinking that if there are many regimes and many ranks, then
-- the output is quite big, and it may be nice to be able to save it
-- and read the results in later to continue computing rather than
-- recomputing. Because of the combinatorial nature of the algorithm
-- (computing all subdeterminants!), it does not take a very big matrix
-- to get into many regimes. But I now have second thoughts of this
-- design, since most of the time, the results are just intermediate,
-- passed to be further processed. On the other hand, there is probably
-- no penalty in leaving the options as is.

-- MB: The following macros are data structures to store mostly
-- intermediate results
-- Rec stores a subdeterminant with corresponding row and column indices
-- Fgb is a Groebner basis for the ideal generated by the subdeterminants
-- of a given rank.
-- Linsys specifies a linearly independent system of a given system
-- assuming a given rank, using given row and column indices
-- Linsoln stores the solution to the parametric linear system as a basis
-- and a particular solution (for a given regime)
-- Rec2 stores the rank, and a list of subdeterminants of that rank,
-- and a Groebner basis for the ideal they generate.
-- Rec3 stores a regime and the corresponding solution; the regime is
-- given by a list of equations (eqzro) and one inequation (neqzro)
-- describing the quasi-algebraic set which is the regime; the
-- additional consistency conditions due to the rhs is given by wcond.
-- Ranksolns stores a list of regimes and their solutions, and the number
-- of regimes all together.
-- Rec8 (temporary) stores a quasi-algebraic set with an indication
-- whether it is empty (sysok = false) or not (sysok = true).

-- I think psolve should be renamed parametricSolve, or even
-- parametricLinearSolve. On the other hand, may be just solve will do.
-- Please feel free to change it to conform with system conventions.
-- Most psolve routines return a list of regimes and solutions,
-- except those that output to file when the number of regimes is
-- returned instead.
-- This version has been tested on the pc version 1.608 March 13, 1992

 ++ modulo the ideal generated by the groebner basis g
regime: (Rec,M GR,L GF,L L GR,NNI,NNI,Inputmode) -> Rec3
 ++ regime(y,c, w, p, r, rm, m) returns a regime,
 ++ a list of polynomials specifying the consistency conditions,
 ++ a particular solution and basis representing the general
 ++ solution of the parametric linear system $c z = w$
 ++ on that regime. The regime returned depends on
 ++ the subdeterminant y.det and the row and column indices.
 ++ The solutions are simplified using the assumption that
 ++ the system has rank r and maximum rank rm. The list p
 ++ represents a list of list of factors of polynomials in
 ++ a groebner basis of the ideal generated by higher order
 ++ subdeterminants, and ius used for the simplification.
 ++ The mode m
 ++ distinguishes the cases when the system is homogeneous,
 ++ or the right hand side is arbitrary, or when there is no
 ++ new right hand side variables.
sqfree: GR -> GR
 ++ sqfree(p) returns the product of square free factors of p
inconsistent?: L GR -> Boolean
 ++ inconsistant?(pl) returns true if the system of equations
 ++ $p = 0$ for p in pl is inconsistent. It is assumed
 ++ that pl is a groebner basis.
 -- this is needed because of change to
 -- EuclideanGroebnerBasisPackage
inconsistent?: L PR -> Boolean
 ++ inconsistant?(pl) returns true if the system of equations
 ++ $p = 0$ for p in pl is inconsistent. It is assumed
 ++ that pl is a groebner basis.
 -- this is needed because of change to
 -- EuclideanGroebnerBasisPackage

partitions: (I,I,I) -> ST L I

```

```

++\spad{partitions(p,l,n)} is the stream of partitions
++ of n whose number of parts is no greater than p
++ and whose largest part is no greater than l.
partitions: I -> ST L I
++\spad{partitions(n)} is the stream of all partitions of n.
partitions: (I,I) -> ST L I
++\spad{partitions(p,l)} is the stream of all
++ partitions whose number of
++ parts and largest part are no greater than p and l.
conjugate: L I -> L I
++\spad{conjugate(pt)} is the conjugate of the partition pt.
conjugates: ST L I -> ST L I
++\spad{conjugates(lp)} is the stream of conjugates of a stream
++ of partitions lp.
shuffle: (L I,L I) -> ST L I
++\spad{shuffle(l1,l2)} forms the stream of all shuffles of l1
++ and l2, i.e. all sequences that can be formed from
++ merging l1 and l2.
shufflein: (L I,ST L I) -> ST L I
++\spad{shufflein(l,st)} maps shuffle(l,u) on to all
++ members u of st, concatenating the results.
sequences: (L I,L I) -> ST L I
++\spad{sequences(l1,l2)} is the stream of all sequences that
++ can be composed from the multiset defined from
++ two lists of integers l1 and l2.
++ For example,the pair \spad{([1,2,4],[2,3,5])} represents
++ multi-set with 1 \spad{2}, 2 \spad{3}'s, and 4 \spad{5}'s.
sequences: L I -> ST L I
++ \spad{sequences([l0,l1,l2,...,ln])} is the set of
++ all sequences formed from
++ \spad{l0} 0's,\spad{l1} 1's,\spad{l2} 2's,...,\spad{ln} n's.
permutations: I -> ST L I
++\spad{permutations(n)} is the stream of permutations
++ formed from \spad{1,2,3,...,n}.

```

<package PATTERN1 PatternFunctions1>≡
)abbrev package PATTERN1 PatternFunctions1
++ Utilities for handling patterns
++ Author: Manuel Bronstein
++ Date Created: 28 Nov 1989
++ Date Last Updated: 5 Jul 1990
++ Description: Tools for patterns;
++ Keywords: pattern, matching.
PatternFunctions1(R:SetCategory, D:Type): with
 suchThat : (Pattern R, D -> Boolean) -> Pattern R
 ++ suchThat(p, f) makes a copy of p and adds the predicate
 ++ f to the copy, which is returned.
 suchThat : (Pattern R, List(D -> Boolean)) -> Pattern R
 ++ \spad{suchThat(p, [f1,...,fn])} makes a copy of p and adds the
 ++ predicate f1 and ... and fn to the copy, which is returned.
 suchThat : (Pattern R, List Symbol, List D -> Boolean) -> Pattern R
 ++ \spad{suchThat(p, [a1,...,an], f)} returns a copy of p with
 ++ the top-level predicate set to \spad{f(a1,...,an)}.
 predicate : Pattern R -> (D -> Boolean)
 ++ predicate(p) returns the predicate attached to p, the
 ++ constant function true if p has no predicates attached to it.
 satisfy? : (D, Pattern R) -> Boolean
 ++ satisfy?(v, p) returns f(v) where f is the predicate
 ++ attached to p.
 satisfy? : (List D, Pattern R) -> Boolean
 ++ \spad{satisfy?([v1,...,vn], p)} returns \spad{f(v1,...,vn)}
 ++ where f is the
 ++ top-level predicate attached to p.

```

```

addBadValue: (Pattern R, D) -> Pattern R
 ++ addBadValue(p, v) adds v to the list of "bad values" for p;
 ++ p is not allowed to match any of its "bad values".
badValues : Pattern R -> List D
 ++ badValues(p) returns the list of "bad values" for p;
 ++ p is not allowed to match any of its "bad values".

(package PATMATCH PatternMatch)≡
)abbrev package PATMATCH PatternMatch
++ Top-level pattern matching functions
++ Author: Manuel Bronstein
++ Date Created: 3 Dec 1989
++ Date Last Updated: 29 Jun 1990
++ Description:
++ This package provides the top-level pattern matching functions.
++ Keywords: pattern, matching.
PatternMatch(Base, Subject, Pat): Exports == Implementation where
 Base : SetCategory
 Subject: PatternMatchable Base
 Pat : ConvertibleTo Pattern Base

Exports ==> with
 is?: (Subject, Pat) -> Boolean
 ++ is?(expr, pat) tests if the expression expr matches
 ++ the pattern pat.
 is?: (List Subject, Pat) -> Boolean
 ++ is?([e1,...,en], pat) tests if the list of
 ++ expressions \spad{[e1,...,en]} matches
 ++ the pattern pat.
 Is : (List Subject, Pat) ->
 PatternMatchListResult(Base, Subject, List Subject)
 ++ Is([e1,...,en], pat) matches the pattern pat on the list of
 ++ expressions \spad{[e1,...,en]} and returns the result.
 if Subject has RetractableTo(Symbol) then
 Is: (Subject, Pat) -> List Equation Subject

```

```

++ Is(expr, pat) matches the pattern pat on the expression
++ expr and returns a list of matches \spad{[v1 = e1,...,vn = en]};
++ returns an empty list if either expr is exactly equal to
++ pat or if pat does not match expr.
else
if Subject has Ring then
Is: (Subject, Pat) -> List Equation Polynomial Subject
++ Is(expr, pat) matches the pattern pat on the expression
++ expr and returns a list of matches \spad{[v1 = e1,...,vn = en]};
++ returns an empty list if either expr is exactly equal to
++ pat or if pat does not match expr.
else
Is: (Subject, Pat) -> PatternMatchResult(Base, Subject)
++ Is(expr, pat) matches the pattern pat on the expression
++ expr and returns a match of the form \spad{[v1 = e1,...,vn = en]};
++ returns an empty match if expr is exactly equal to pat.
++ returns a \spadfun{failed} match if pat does not match expr.

Implementation ==> add
import PatternMatchListAggregate(Base, Subject, List Subject)

ist: (Subject, Pat) -> PatternMatchResult(Base, Subject)

## 17.27 package PMASS PatternMatchAssertions

## 17.28 PatternMatchAssertions

### Exports:

```

assert constant multiple optional
<package PMASS PatternMatchAssertions>≡
)abbrev package PMASS PatternMatchAssertions
++ Assertions for pattern-matching
++ Author: Manuel Bronstein
++ Description: Attaching assertions to symbols for pattern matching.
++ Date Created: 21 Mar 1989
++ Date Last Updated: 23 May 1990
++ Keywords: pattern, matching.
PatternMatchAssertions(): Exports == Implementation where
 FE ==> Expression Integer

Exports ==> with
 assert : (Symbol, String) -> FE
 ++ assert(x, s) makes the assertion s about x.
 constant: Symbol -> FE
 ++ constant(x) tells the pattern matcher that x should
 ++ match only the symbol 'x and no other quantity.
 optional: Symbol -> FE
 ++ optional(x) tells the pattern matcher that x can match
 ++ an identity (0 in a sum, 1 in a product or exponentiation).;
 multiple: Symbol -> FE
 ++ multiple(x) tells the pattern matcher that x should
 ++ preferably match a multi-term quantity in a sum or product.
 ++ For matching on lists, multiple(x) tells the pattern matcher
 ++ that x should match a list instead of an element of a list.

Implementation ==> add
 import FunctionSpaceAssertions(Integer, FE)

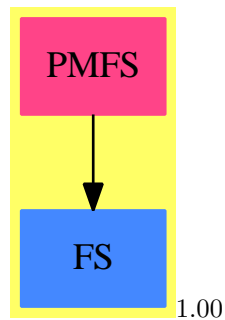

```

```
constant x == constant(x::FE)
multiple x == multiple(x::FE)
optional x == optional(x::FE)
assert(x, s) == assert(x::FE, s)
