

# Package ‘OOR’

January 20, 2025

**Type** Package

**Title** Optimistic Optimization in R

**Version** 0.1.4

**Date** 2023-08-22

**Description** Implementation of optimistic optimization methods for global optimization of deterministic or stochastic functions. The algorithms feature guarantees of the convergence to a global optimum. They require minimal assumptions on the (only local) smoothness, where the smoothness parameter does not need to be known. They are expected to be useful for the most difficult functions when we have no information on smoothness and the gradients are unknown or do not exist. Due to the weak assumptions, however, they can be mostly effective only in small dimensions, for example, for hyperparameter tuning.

**License** LGPL

## Description

This package implements optimistic optimization methods [1,2,3] for global optimization of deterministic or stochastic functions. The algorithms feature guarantees of the convergence to a global optimum. They require minimal assumptions on the (only local) smoothness, where the smoothness parameter does not need to be known. They are expected to be useful for the most difficult functions when we have no information on smoothness and the gradients are unknown or do not exist. Due to the weak assumptions, however, they can be mostly effective only in small dimensions, for example, for hyperparameter tuning [4].

## Details

Important functions:

[StoS00](#)

[POO](#)

## Note

This package is based on the Matlab and Python implementations from the corresponding publications, available from the following webpage: <https://team.inria.fr/sequel/software/>.

## Examples

```

#-----
# Example 1 : Deterministic optimization with S00
#-----
## Define objective
fun1 <- function(x) return(-guirland(x))

## Optimization
Sol1 <- StoS00(par = NA, fn = fun1, nb_iter = 1000, control = list(type = "det", verbose = 1))

## Display objective function and solution fund
curve(fun1, n = 1001)
abline(v = Sol1$par, col = 'red')

#-----
# Example 2 : Stochastic optimization with StoS00
#-----
set.seed(42)

## 2-dimensional noisy objective function, defined on  $[0, \pi/4]^2$ 
fun2 <- function(x){return(-sin1(x[1]) * sin1(1 - x[2]) + runif(1, min = -0.05, max = 0.05))}

## Optimizing
Sol2 <- StoS00(par = rep(NA, 2), fn = fun2, upper = rep(pi/4, 2), nb_iter = 1000)

## Display solution
xgrid <- seq(0, pi/4, length.out = 101)
Xgrid <- expand.grid(xgrid, xgrid)
ref <- apply(Xgrid, 1, function(x){(-sin1(x[1]) * sin1(1 - x[2]))})
filled.contour(xgrid, xgrid, matrix(ref, 101), color.palette = terrain.colors,
plot.axes = {axis(1); axis(2); points(Xgrid[which.min(ref),, drop = FALSE], pch = 21);
              points(Sol2$par[1], Sol2$par[2], pch = 13)})

## Not run:
#-----
# Example 3 : Stochastic optimization with P00
#-----
set.seed(10)
noise.level <- 0.05

## Define and display objective
fun3 <- function(x){return(double_sine(x) + runif(1, min = -noise.level, max = noise.level))}
xgrid <- seq(0, 1, length.out = 1000)
plot(xgrid, sapply(xgrid, double_sine), type = 'l', ylab = "double_sine(x)", xlab = 'x')

## Maximization
Sol3 <- P00(fun3, horizon = 1000, noise.level = noise.level)

## Display result
abline(v = Sol3$par)

## End(Not run)

```

---

plotStoS00

*Plot 2-D StoS00 result*

---

## Description

Plot bivariate tree structure obtained when running [StoS00](#)

## Usage

```
plotStoS00(
  sol,
  lower = rep(0, length(sol$par)),
  upper = rep(1, length(sol$par)),
  levels = NULL,
  add = FALSE,
  cpch = ".",
  lcols = 1,
  ylim = NULL
)
```

## Arguments

sol	outcome of running <a href="#">StoS00</a> , with control\$light set to FALSE
lower, upper	vectors of bounds on the variables.
levels	which levels to print. Default to all levels
add	if TRUE, use existing plot
cpch	<a href="#">points</a> pch code for the centers
lcols	color at each level, or a single color for all levels (default)
ylim	vector of bounds, required in the 1d case

## Examples

```
#-----
# Example 1 : Deterministic optimization with S00, 1-dimensional function
#-----
## Define objective
fun1 <- function(x) return(-guirland(x))

## Optimization
Sol1 <- StoS00(par = NA, fn = fun1, nb_iter = 1000,
  control = list(type = "det", verbose = 1, light = FALSE))

## Display objective function and solution found
curve(fun1, n = 1001, ylim = c(-1.3, 0))
abline(v = Sol1$par, col = 'red')
plotStoS00(Sol1, ylim = c(-1.3, -1.1), add = TRUE)
```

```

#-----
# Example 2 : Deterministic optimization with S00, 2-dimensional function
#-----
set.seed(42)

## 2-dimensional noiseless objective function, defined on [0, pi/4]^2
fun <- function(x){return(-sin1(x[1]) * sin1(1 - x[2]))}

## Optimizing
Sol <- StoS00(par = rep(NA, 2), fn = fun, upper = rep(pi/4, 2), nb_iter = 1000,
  control = list(type = 'det', light = FALSE))

## Display solution
plotStoS00(Sol, upper = rep(pi/4, 2))

```

---

POO

---

*Parallel Optimistic Optimization*

---

## Description

Global optimization of a blackbox function given a finite budget of noisy evaluations, via the Parallel Optimistic Optimization algorithm. The knowledge of the function's smoothness is not required.

## Usage

```
POO(f, horizon = 100, noise.level, rhomax = 20, nu = 1)
```

## Arguments

f	function to maximize.
horizon	maximum number of function evaluations.
noise.level	scalar bound on the noise value.
rhomax	number of equidistant rho values in [0,1], that are used by the corresponding HOO subroutines, see Details.
nu	scalar (> 0) assessing the complexity of the function, along with rho (see the near optimality definition in the reference below).

## Details

Only 1-dimensional functions defined on [0, 1] are handled so far. POO uses Hierarchical Optimistic Optimisation (HOO) as a subroutine, whose number is set by rhomax. POO handles more difficult functions than [StoS00](#).

**Value**

Random point evaluated by the best HOO, in the form of a list with elements:

- par parameter value at this point,
- value noisy value at par,
- best\_rho best rho value.

**Examples**

```
## Not run:
#-----
# Maximization with P00
#-----
set.seed(10)
noise.level <- 0.05

## Define and display objective
ftest <- function(x){return(double_sine(x) + runif(1, min = -noise.level, max = noise.level))}
xgrid <- seq(0, 1, length.out = 1000)
plot(xgrid, sapply(xgrid, double_sine), type = 'l', ylab = "double_sine(x)", xlab = 'x')

## Optimization
Sol <- P00(ftest, horizon = 1000, noise.level = noise.level)

## Display result
abline(v = Sol$par)

## End(Not run)
```

**Description**

Global optimization of a blackbox function given a finite budget of noisy evaluations, via the Stochastic-Simultaneous Optimistic Optimisation algorithm. The deterministic-SOO method is available for noiseless observations. The knowledge of the function's smoothness is not required.

**Usage**

```
StoS00(
  par,
  fn,
  ...,
  lower = rep(0, length(par)),
  upper = rep(1, length(par)),
  nb_iter,
  control = list(verbose = 0, type = "sto", max = FALSE, light = TRUE)
)
```

**Arguments**

par	vector with length defining the dimensionality of the optimization problem. Providing actual values of par is not necessary (NAs are just fine). Included primarily for compatibility with <code>optim</code> .
fn	scalar function to be minimized, with first argument to be optimized over.
...	optional additional arguments to fn.
lower, upper	vectors of bounds on the variables.
nb_iter	number of function evaluations allocated to optimization.
control	list of control parameters: <ul style="list-style-type: none"> <li>• verbose: verbosity level, either 0 (default), 1 or greater than 1,</li> <li>• type: either 'det' for optimizing a deterministic function or 'sto' for a stochastic one,</li> <li>• k_max: maximum number of evaluations per leaf (default: from analysis),</li> <li>• h_max: maximum depth of the tree (default: from analysis),</li> <li>• delta: confidence (default: <math>1/\sqrt{\text{nb\_iter}}</math>) - from analysis),</li> <li>• light: set to FALSE to return the search tree,</li> <li>• max: if TRUE, performs maximization.</li> </ul>

**Details**

The optional tree element returned is a list, whose first element is the root node and the last element the deepest nodes. At each level, `x` provides the center(s), one per row, whose corresponding bounds are given by `x_min` and `x_max`. Then:

- leaf indicates if `x` is a leaf (1 if TRUE);
- new indicates if `x` has been sampled last;
- sums gives the sum of values at `x`;
- bs is for the upper bounds at `x`;
- ks is the number of evaluations at `x`;
- values stores the values evaluated as they come (mostly useful in the deterministic case)

**Value**

list with components:

- par best set of parameters (for a stochastic function, it corresponds to the minimum reached over the deepest unexpanded node),
- value value of fn at par,
- tree search tree built during the execution, not returned unless `control$light == TRUE`.

  control = list(type = 'det', light = FALSE))

## Display solution
xgrid <- seq(0, pi/4, length.out = 101)
Xgrid <- expand.grid(xgrid, xgrid)
ref <- apply(Xgrid, 1, function(x){(-sin1(x[1]) * sin1(1 - x[2]))})
filled.contour(xgrid, xgrid, matrix(ref, 101), color.palette = terrain.colors,
plot.axes = {axis(1); axis(2); plotStoS00(Sol4, add = TRUE, upper = rep(pi/4, 2));
           points(Xgrid[which.min(ref),, drop = FALSE], pch = 21);
           points(Sol4$par[1], Sol4$par[2], pch = 13, col = 2)})

```

---

Test functions

*Test functions of x*

---

### Description

Several test functions of varying complexity are available. They are defined on  $[0,1]$ .

**Usage**

```
guirland(x)
```

```
sin1(x)
```

```
difficult(x)
```

```
difficult2(x)
```

```
double_sine(x, rho1 = 0.3, rho2 = 0.8, tmax = 0.5)
```

**Arguments**

x                    vector specifying the location where the function is to be evaluated.  
rho1, rho2, tmax    additional parameters for double\_sine.

**Details**

These test functions are translated from the Matlab and Python codes in the references.

**Examples**

```
par(mfrow = c(2,3))

curve(guirland, n = 501)
curve(sin1)
curve(difficult, xlim = c(1e-8, 1), n = 1001)
xgrid <- seq(0, 1, length.out = 500)
plot(xgrid, sapply(xgrid, difficult2), type = 'l', ylab = "difficult2(x)")
plot(xgrid, sapply(xgrid, double_sine), type = 'l', ylab = "double_sine(x) (default)")
double_sine2 <- function(x) double_sine(x, rho1 = 0.8, rho2 = 0.3)
plot(xgrid, sapply(xgrid, double_sine2), type = 'l', ylab = "double_sine(x) (modified)")

par(mfrow = c(1,1))
```
