Package 'blocklength'

February 17, 2025

Type Package

Title Select an Optimal Block-Length to Bootstrap Dependent Data (Block Bootstrap)

Version 0.2.0

Maintainer Alec Stashevsky <alec@alecstashevsky.com>

Description A set of functions to select the optimal block-length for a dependent bootstrap (block-bootstrap). Includes the Hall, Horowitz, and Jing (1995) <doi:10.1093/biomet/82.3.561> subsampling-based cross-validation method, the Politis and White (2004) <doi:10.1081/ETC-120028836> Spectral Density Plug-in method, including the Patton, Politis, and White (2009) <doi:10.1080/07474930802459016> correction, and the Lahiri, Furukawa, and Lee (2007) <doi:10.1016/j.stamet.2006.08.002> nonparametric plug-in method, with a corresponding set of S3 plot methods.

`hhj` *Hall, Horowitz, and Jing (1995) "HHJ" Algorithm to Select the Optimal Block-Length*

Description

Perform the Hall, Horowitz, and Jing (1995) "HHJ" cross-validation algorithm to select the optimal block-length for a bootstrap on dependent data (block-bootstrap). Dependent data such as stationary time series are suitable for usage with the HHJ algorithm.

Usage

```
hhj(
  series,
  nb = 100L,
  n_iter = 10L,
  pilot_block_length = NULL,
  sub_sample = NULL,
  k = "two-sided",
  bofb = 1L,
  search_grid = NULL,
  grid_step = c(1L, 1L),
  cl = NULL,
  verbose = TRUE,
  plots = TRUE
)
```

Arguments

`series`	a numeric vector or time series giving the original data for which to find the optimal block-length for.
`nb`	an integer value, number of bootstrapped series to compute.
`n_iter`	an integer value, maximum number of iterations for the HHJ algorithm to compute.
`pilot_block_length`	a numeric value, the block-length ($l*$ in *HHJ*) for which to perform initial block bootstraps.

sub_sample	a numeric value, the length of each overlapping subsample, m in *HHJ*.
k	a character string, either "bias/variance", "one-sided", or "two-sided" depending on the desired object of estimation. If the desired bootstrap statistic is bias or variance then select "bias/variance" which sets $k = 3$ per HHJ. If the object of estimation is the one-sided or two-sided distribution function, then set k = "one-sided" or k = "two-sided" which sets $k = 4$ and $k = 5$, respectively. For the purpose of generating symmetric confidence intervals around an unknown parameter, k = "two-sided" (the default) should be used.
bofb	a numeric value, length of the basic blocks in the *block-of-blocks* bootstrap, *see* m = for tsbootstrap and Kunsch (1989).
search_grid	a numeric value, the range of solutions around $l*$ to evaluate within the MSE function *after* the first iteration. The first iteration will search through all the possible block-lengths unless specified in grid_step = .
grid_step	a numeric value or vector of at most length 2, the number of steps to increment over the subsample block-lengths when evaluating the MSE function. If grid_step = 1 then each block-length will be evaluated in the MSE function. If grid_step > 1, the MSE function will search over the sequence of block-lengths from 1 to m by grid_step. If grid_step is a vector of length 2, the first iteration will step by the first element of grid_step and subsequent iterations will step by the second element.
cl	a cluster object, created by package **parallel**, **doParallel**, or **snow**. If NULL, no parallelization will be used.
verbose	a logical value, if set to FALSE then no interim messages are output to the console. Error messages will still be output. Default is TRUE.
plots	a logical value, if set to FALSE then no interim plots are output to the console. Default is TRUE.

Details

The HHJ algorithm is computationally intensive as it relies on a cross-validation process using a type of subsampling to estimate the mean squared error (MSE) incurred by the bootstrap at various block-lengths.

Under-the-hood, hhj() makes use of tsbootstrap, *see* Trapletti and Hornik (2020), to perform the moving block-bootstrap (or the *block-of-blocks* bootstrap by setting bofb > 1) according to Kunsch (1989).

Value

an object of class 'hhj'

Examples

```
# Generate AR(1) time series
sim <- stats::arima.sim(list(order = c(1, 0, 0), ar = 0.5),
                        n = 500, innov = rnorm(500))

# Calculate optimal block length for series
hhj(sim, sub_sample = 10)

# Use parallel computing
library(parallel)

# Make cluster object with 2 cores
cl <- makeCluster(2)

# Calculate optimal block length for series
hhj(sim, cl = cl)
```

---

nppi *Lahiri, Furukawa, and Lee (2007) Nonparametric Plug-In "NPPI" Rule to Select the Optimal Block-Length*

Description

This function implements the Nonparametric Plug-In (NPPI) algorithm, as proposed by Lahiri, Furukawa, and Lee (2007), to select the optimal block length for block bootstrap procedures. The NPPI method estimates the optimal block length by balancing bias and variance in block bootstrap estimators, particularly for time series and other dependent data structures. The function also leverages the Moving Block Bootstrap (MBB) method of (Kunsch, 1989) and the Moving Blocks Jackknifte (MBJ) of Liu and Singh (1992).

Usage

```
nppi(
  data,
  stat_function = mean,
  r = 1,
  a = 1,
  l = NULL,
  m = NULL,
  num_bootstrap = 1000,
  c_1 = 1L,
```

```
  epsilon = 1e-08,
  plots = TRUE
)
```

Arguments

data	A numeric vector, ts, or single-column data.frame representing the time series or dependent data.
stat_function	A function to compute the statistic of interest (*e.g.*, mean, variance). The function should accept a numeric vector as input and return a scalar value (default is mean).
r	The rate parameter for the MSE expansion (default is 1). This parameter controls the convergence rate in the bias-variance trade-off.
a	The bias exponent (default is 1). Adjust this based on the theoretical properties of the statistic being bootstrapped.
l	Optional. The initial block size for bias estimation. If not provided, it is set to max(2, round(c_1 * n^{1 / (r + 4)})), where n is the sample size.
m	Optional. The number of blocks to delete in the Jackknife-After-Bootstrap (JAB) variance estimation. If not provided, it defaults to floor(c_2 * n^{1/3} * l^{2/3}).
num_bootstrap	The number of bootstrap replications for bias estimation (default is 1000).
c_1	A tuning constant for initial block size calculation (default is 1).
epsilon	A small constant added to the variance to prevent division by zero (default is 1e-8).
plots	A logical value indicating whether to plot the JAB diagnostic

Details

Jackknife-After-Bootstrap (JAB) variance estimation (Lahiri, 2002).

Value

A object of class nppi with the following components:

optimal_block_length The estimated optimal block length for the block bootstrap procedure.

bias The estimated bias of the block bootstrap estimator.

variance The estimated variance of the block bootstrap estimator using the JAB method.

jab_point_values The point estimates of the statistic for each deletion block in the JAB variance estimation. Used for diagnostic plots

l The initial block size used for bias estimation.

m The number of blocks to delete in the JAB variance estimation.

Examples

```
# Generate AR(1) time series
set.seed(32)
sim <- stats::arima.sim(list(order = c(1, 0, 0), ar = 0.5),
                        n = 500, innov = rnorm(500))

# Estimate the optimal block length for the sample mean
result <- nppi(data = sim, stat_function = mean, num_bootstrap = 500, m = 2)

print(result$optimal_block_length)

# Use S3 method to plot JAB diagnostic
plot(result)
```

`plot.hhj` *Plot MSE Function for HHJ Algorithm*

Description

S3 Method for objects of class 'hhj'

Usage

```
## S3 method for class 'hhj'
plot(x, iter = NULL, ...)
```

Arguments

`x`	an object of class 'hhj'
`iter`	a vector of `hhj()` iterations to plot. `NULL`. All iterations are plotted by default.
`...`	Arguments passed on to `base::plot`
	`y` the y coordinates of points in the plot, *optional* if `x` is an appropriate structure.

Value

No return value, called for side effects

Examples

```
# Generate AR(1) time series
sim <- stats::arima.sim(list(order = c(1, 0, 0), ar = 0.5),
                        n = 500, innov = rnorm(500))

# Generate 'hhj' class object of optimal block length for series
hhj <- hhj(sim, sub_sample = 10)

## S3 method for class 'hhj'
plot(hhj)
```

---

plot.nppi *Plot Stability of JAB Point Estimates*

Description

S3 Method for objects of class 'nppi' This function visualizes the JAB point estimates across deletion blocks indices used to estimate variance of the NPPI algorithm.

Usage

```
## S3 method for class 'nppi'
plot(x, ...)
```

Arguments

x	An object of class nppi, containing JAB point values.
...	Arguments passed on to base::plot
	y the y coordinates of points in the plot, *optional* if x is an appropriate structure.

Value

No return value, called for side effects

Examples

```
# Generate AR(1) time series
set.seed(32)
sim <- stats::arima.sim(list(order = c(1, 0, 0), ar = 0.5),
                        n = 500, innov = rnorm(500))

# Estimate the optimal block length for the sample mean
result <- nppi(data = sim, stat_function = mean, num_bootstrap = 500, m = 2)

# Use s3 method
plot(result)
```

`plot.pwsd` *Plot Correlogram for Politis and White Auto−Correlation Implied Hypothesis Test*

Description

S3 Method for objects of class 'pwsd' *See* `?plot.acf` of the **stats** package for more customization options on the correlogram, from which `plot.pwsd` is based

Usage

```
## S3 method for class 'pwsd'
plot(x, c = NULL, main = NULL, ylim = NULL, ...)
```

Arguments

`x`	an of object of class 'pwsd' or 'acf'
`c`	a numeric value, the constant which acts as the significance level for the implied hypothesis test. Defaults to `qnorm(0.975)` for a two-tailed 95% confidence level. Politis and White (2004) suggest `c = 2`.
`main`	an overall title for the plot, if no string is supplied a default title will be populated. *See* `title`
`ylim`	a numeric of length 2 giving the y-axis limits for the plot
`...`	Arguments passed on to `base::plot`
	`y` the y coordinates of points in the plot, *optional* if `x` is an appropriate structure.

Value

No return value, called for side effects

Examples

```
# Use S3 Method

# Generate AR(1) time series
sim <- stats::arima.sim(list(order = c(1, 0, 0), ar = 0.5),
                        n = 500, innov = rnorm(500))

b <- pwsd(sim, round = TRUE, correlogram = FALSE)
plot(b)
```

`pwsd` *Politis and White (2004) Spectral Density "PWSD" Automatic Block-Length Selection*

Description

Run the Automatic Block-Length selection method proposed by Politis and White (2004) and corrected in Patton, Politis, and White (2009). The method is based on spectral density estimation via flat-top lag windows of Politis and Romano (1995). This code was adapted from `b.star` to add functionality and include correlogram support including an S3 method, *see* Hayfield and Racine (2008).

Usage

```
pwsd(
  data,
  K_N = NULL,
  M_max = NULL,
  m_hat = NULL,
  b_max = NULL,
  c = NULL,
  round = FALSE,
  correlogram = TRUE
)
```

Arguments

`data`	an nxk data.frame, matrix, or vector (if $k = 1$) where the optimal block-length will be computed for each of the k columns.
`K_N`	an integer value, the maximum lags for the auto-correlation, rho_k, which to apply the *implied hypothesis* test. Defaults to `max(5, log(N))`. *See* Politis and White (2004) footnote c.
`M_max`	an integer value, the upper-bound for the optimal number of lags, M, to compute the auto-covariance for. *See* Theorem 3.3 (ii) of Politis and White (2004).

m_hat	an integer value, if set to NULL (the default), then m_hat is estimated as the smallest integer after which the correlogram appears negligible for K_N lags. In problematic cases, setting m_hat to an integer value can be used to override the estimation procedure.
b_max	a numeric value, the upper-bound for the optimal block-length. Defaults to ceiling(min(3 * sqrt(n), n / 3)) per Politis and White (2004).
c	a numeric value, the constant which acts as the significance level for the implied hypothesis test. Defaults to qnorm(0.975) for a two-tailed 95% confidence level. Politis and White (2004) suggest c = 2.
round	a logical value, if set to FALSE then the final block-length output will not be rounded, the default. If set to TRUE the final estimates for the optimal block-length will be rounded to whole numbers.
correlogram	a logical value, if set to TRUE a plot of the correlogram (*i.e.* a plot of $R(k)$ vs. k) will be output to the console. If set to FALSE, no interim plots will be output to the console, but may be plotted later using the corresponding S3 method, plot.pwsd.

Value

an object of class 'pwsd'
