# Package 'distances'

April 1, 2025

Type Package Title Tools for Distance Metrics **Version** 0.1.12 Date 2025-04-01 Description Provides tools for constructing, manipulating and using distance metrics. **Depends** R (>= 3.4.0) Imports stats Suggests testthat **NeedsCompilation** yes License GPL (>= 3) LicenseNote The distances packages includes the ANN library (distributed under the LGPLv2.1 license). URL https://github.com/fsavje/distances BugReports https://github.com/fsavje/distances/issues **Encoding** UTF-8 RoxygenNote 7.3.2 Author Fredrik Savje [aut, cre]

Maintainer Fredrik Savje <rpackages@fredriksavje.com>

**Repository** CRAN

#### distances

# Description

distances constructs a distance metric for a set of points. Currently, it only creates Euclidean distances. It can, however, create distances in any linear projection of Euclidean space. In other words, Mahalanobis distances or normalized Euclidean distances are both possible. It is also possible to give each dimension of the space different weights.

#### Usage

```
distances(
   data,
   id_variable = NULL,
   dist_variables = NULL,
   normalize = NULL,
   weights = NULL
)
```

#### Arguments

data	a matrix or data frame containing the data points between distances should be derived.
id_variable	optional IDs of the data points. If id_variable is a single string and data is a data frame, the corresponding column in data will be taken as IDs. That column will be excluded from data when constructing distances (unless it is listed in dist_variables). If id_variable is NULL, the IDs are set to 1:nrow(data). Otherwise, id_variable must be of length nrow(data) and will be used directly as IDs.
dist_variables	optional names of the columns in data that should be used when constructing distances. If dist_variables is NULL, all columns will be used (net of eventual column specified by id_variable). If data is a matrix, dist_variables must be NULL.
normalize	optional normalization of the data prior to distance construction. If normalize is NULL or "none", no normalization will be done (effectively setting normalize to the identity matrix). If normalize is "mahalanobize", normalization will be done with var(data) (i.e., resulting in Mahalanobis distances). If normalize is "studentize", normalization is done with the diagonal of var(data). If normalize is a matrix, it will be used in the normalization. If normalize is a vector, a diagonal matrix with the supplied vector as its diagonal will be used. The matrix used for normalization must be positive-semidefinite.
weights	optional weighting of the data prior to distance construction. If normalize is NULL no weighting will be done (effectively setting weights to the identity matrix). If weights is a matrix, that will be used in the weighting. If normalize is a vector, a diagonal matrix with the supplied vector as its diagonal will be used. The matrix used for weighting must be positive-semidefinite.

#### distances

#### **Details**

Let x and y be two data points in data described by two vectors. distances uses the following metric to derive the distance between x and y:

$$\sqrt{(x-y)N^{-0.5}W(N^{-0.5})'(x-y)}$$

where  $N^{-0.5}$  is the Cholesky decomposition (lower triangular) of the inverse of the matrix speficied by normalize, and W is the matrix speficied by weights.

When normalize is var(data) (i.e., using the "mahalanobize" option), the function gives (weighted) Mahalanobis distances. When normalize is diag(var(data)) (i.e., using the "studentize" option), the function divides each column by its variance leading to (weighted) normalized Euclidean distances. If normalize is the identity matrix (i.e., using the "none" or NULL option), the function derives ordinary Euclidean distances.

#### Value

Returns a distances object.

#### Examples

```
my_data_points <- data.frame(x = c(1, 2, 3, 4, 5, 6, 7, 8, 9, 10),</pre>
                               y = c(10, 9, 8, 7, 6, 6, 7, 8, 9, 10))
# Euclidean distances
my_distances1 <- distances(my_data_points)</pre>
# Euclidean distances in only one dimension
my_distances2 <- distances(my_data_points,</pre>
                            dist_variables = "x")
# Mahalanobis distances
my_distances3 <- distances(my_data_points,</pre>
                            normalize = "mahalanobize")
# Custom normalization matrix
my_norm_mat <- matrix(c(3, 1, 1, 3), nrow = 2)</pre>
my_distances4 <- distances(my_data_points,</pre>
                            normalize = my_norm_mat)
# Give "x" twice the weight compared to "y"
my_distances5 <- distances(my_data_points,</pre>
                            weights = c(2, 1))
# Use normalization and weighting
my_distances6 <- distances(my_data_points,</pre>
                            normalize = "mahalanobize",
                             weights = c(2, 1))
# Custom ID labels
my_data_points_withID <- data.frame(my_data_points,</pre>
                                      my_ids = letters[1:10])
```

distance\_columns

```
my_distances7 <- distances(my_data_points_withID,</pre>
                             id_variable = "my_ids")
# Compare to standard R functions
all.equal(as.matrix(my_distances1), as.matrix(dist(my_data_points)))
# > TRUE
all.equal(as.matrix(my_distances2), as.matrix(dist(my_data_points[, "x"])))
# > TRUE
tmp_distances <- sqrt(mahalanobis(as.matrix(my_data_points),</pre>
                                    unlist(my_data_points[1, ]),
                                    var(my_data_points)))
names(tmp_distances) <- 1:10</pre>
all.equal(as.matrix(my_distances3)[1, ], tmp_distances)
# > TRUE
tmp_data_points <- as.matrix(my_data_points)</pre>
tmp_data_points[, 1] <- sqrt(2) * tmp_data_points[, 1]</pre>
all.equal(as.matrix(my_distances5), as.matrix(dist(tmp_data_points)))
# > TRUE
tmp_data_points <- as.matrix(my_data_points)</pre>
tmp_cov_mat <- var(tmp_data_points)</pre>
tmp_data_points[, 1] <- sqrt(2) * tmp_data_points[, 1]</pre>
tmp_distances <- sqrt(mahalanobis(tmp_data_points,</pre>
                                    tmp_data_points[1, ],
                                    tmp_cov_mat))
names(tmp_distances) <- 1:10</pre>
all.equal(as.matrix(my_distances6)[1, ], tmp_distances)
# > TRUE
tmp_distances <- as.matrix(dist(my_data_points))</pre>
colnames(tmp_distances) <- rownames(tmp_distances) <- letters[1:10]</pre>
all.equal(as.matrix(my_distances7), tmp_distances)
# > TRUE
```

distance\_columns Distance matrix columns

#### Description

distance\_columns extracts columns from the distance matrix.

#### Usage

```
distance_columns(distances, column_indices, row_indices = NULL)
```

4

#### distance\_matrix

#### Arguments

distances	A distances object.
column_indices	An integer vector with point indices indicating which columns to be extracted.
row_indices	If NULL, complete rows will be extracted. If integer vector with point indices, only the indicated rows will be extracted.

#### Details

If the complete distance matrix is desired, distance\_matrix is faster than distance\_columns.

#### Value

Returns a matrix with the requested columns.

distance\_matrix Distance matrix

# Description

distance\_matrix makes distance matrices (complete and partial) from distances objects.

#### Usage

distance\_matrix(distances, indices = NULL)

#### Arguments

distances	A distances object.
indices	If NULL, the complete distance matrix is made. If integer vector with point in- dices, a partial matrix including only the indicated data points is made.

## Value

Returns a distance matrix of class dist.

is.distances

# Description

is. distances checks whether the provided object is a valid instance of the distances class.

#### Usage

is.distances(x)

#### Arguments

х

object to check.

## Value

Returns TRUE if x is a valid distances object, otherwise FALSE.

max\_distance\_search Max distance search

#### Description

max\_distance\_search searches for the data point furthest from a set of query points.

#### Usage

```
max_distance_search(distances, query_indices = NULL, search_indices = NULL)
```

#### Arguments

distances	A distances object.
query_indices	An integer vector with point indices to query. If NULL, all data points in distances are queried.
<pre>search_indices</pre>	An integer vector with point indices to search among. If NULL, all data points in distances are searched over.

#### Value

An integer vector with point indices for the data point furthest from each query.

 $nearest_neighbor_search$ 

Nearest neighbor search

#### Description

nearest\_neighbor\_search searches for the k nearest neighbors of a set of query points.

#### Usage

```
nearest_neighbor_search(
  distances,
  k,
  query_indices = NULL,
  search_indices = NULL,
  radius = NULL
)
```

# Arguments

distances	A distances object.
k	The number of neighbors to search for.
query_indices	An integer vector with point indices to query. If NULL, all data points in distances are queried.
search_indices	An integer vector with point indices to search among. If NULL, all data points in distances are searched over.
radius	Restrict the search to a fixed radius around each query. If fewer than k search points exist within this radius, no neighbors are reported (indicated by NA).

#### Value

A matrix with point indices for the nearest neighbors. Columns in this matrix indicate queries, and rows are ordered by distances from the query.
