Introduction	1	1
Sorting	6	3
A bugfix	9	4
Index	11	5

Editor's Note: The present variant of this `C/WEB` source file has been modified for use in the `TEX` Live system.
The following sections were changed by the change file: [1](#), [2](#), [4](#), [5](#), [6](#), [9](#), [10](#), [11](#).

1* Introduction. This short program sorts the mini-indexes of listings prepared by CTWILL.

More precisely, suppose you have said `ctwill foo.w`, getting a file `foo.tex`, and that you've then said `tex foo.tex`, getting files `foo.dvi` and `foo.ref`. If you're happy with `foo.dvi` except for the alphabetic order of the mini-indexes, you can then say

```
refsort <foo.ref >foo.sref
```

after which `tex foo` will produce `foo.dvi` again, this time with the mini-indexes in order.

Still more precisely, this program reads from standard input a file consisting of groups of unsorted lines and writes to standard output a file consisting of groups of sorted lines. Each input group begins with an identification line whose first character is `!`; the remaining characters are a page number. The other lines in the group all have the form

$$+_ \alpha _ \backslash ? \{ \kappa \} \omega$$

where α is a string containing no spaces, $?$ is a single character, κ is a string of letters, digits, and `_`'s, and ω is an arbitrary string. The output groups contain the same lines without the initial `+_`, sorted alphabetically with respect to the κ fields, followed by a closing line that says `\donewithpage` followed by the page number copied from the original identification line.

Exception: In the case of a "custom" identifier, `\?{\kappa}` takes the alternative form `\$ \kappa _ \$` instead.

We define limits on the number and size of mini-index entries that should be plenty big enough.

```
#define max_key 50    > greater than the length of the longest identifier <
#define max_size 120  > greater than the length of the longest mini-index entry <
#define max_items 300 > the maximum number of items in a single mini-index <
```

2* Here's the layout of the C program:

```
#define abort(c, m)
    {
        fprintf(stderr, "%s!\n%s", m, buf); return c;
    }

#include <stdio.h>
#include <string.h>
#include <ctype.h>

typedef struct {
    char key[max_key];
    char entry[max_size];
} item;
item items[max_items];    ▷ all items of current group ◁
item *sorted[max_items];  ▷ pointers to items in alphabetic order ◁
char cur_page[10];        ▷ page number, as a string ◁
char buf[max_size];       ▷ current line of input ◁
char *input_status;       ▷ Λ if end of input reached, else buf ◁

int main()
{
    char *p, *q;
    int n;    ▷ current number of items ◁
    item *x, **y;
    input_status ← fgets(buf, max_size, stdin);
    while (input_status) {
        ◁ Check that buf contains a valid page-number line 3);
        ◁ Read and sort additional lines, until buf terminates a group 4*);
        ◁ Output the current group 5*);
    }
    return 0;    ▷ normal exit ◁
}
```

4* ◁ Read and sort additional lines, until buf terminates a group 4*) ≡
 $n \leftarrow 0$;
while (1) {

 if (input_status ≡ Λ ∨ *buf ≠ '+') **break**;
 x ← &items[n]; ◁ Copy buf to item x 6*);
 ◁ Sort the new item into its proper place 8);
 if (++n > max_items) abort(-11, "too_many_lines_in_group");
}

This code is used in section 2*.

5* ◁ Output the current group 5*) ≡
{
 for (y ← sorted; y < sorted + n; y++) printf("%s\n", (*y)→entry);
 printf("\donewithpage%s\n", cur_page);
}

This code is used in section 2*.

6* Sorting. We convert the key to lowercase as we copy it, and we omit backslashes. We also convert `_` to `␣`. Then `_` will be alphabetically less than alphabetic letters, as desired.

```

⟨Copy buf to item x 6*⟩ ≡
  if (*(buf + 1) ≠ '␣') abort(-3, "missing_␣blank_␣after_␣+");
  ⟨Scan past α 9*⟩;
  if (*p ≠ '␣') abort(-4, "missing_␣blank_␣after_␣alpha");
  if (*(p + 1) ≡ '$') ⟨Process a custom-formatted identifier 7⟩
  else {
    if (*(p + 1) ≠ '\\') abort(-5, "missing_␣backslash");
    if (¬*(p + 2)) abort(-6, "missing_␣control_␣code");
    if (*(p + 3) ≠ '{') abort(-7, "missing_␣left_␣brace");
    for (p += 4, q ← x-key; *p ≠ '}' ^ *p; p++) {
      if (*p ≠ '\\') {
        if (isupper(*p)) *q++ ← *p + ('a' - 'A');
        else if (*p ≡ '_') *q++ ← '␣';
        else *q++ ← *p;
      }
    }
    if (*p ≠ '}') abort(-8, "missing_␣right_␣brace");
  }
  if (q ≥ &x-key[max_key]) abort(-9, "key_␣too_␣long");
  *q ← '\0'; ⟨Copy the buffer to x-entry 10*⟩;
  if (p ≡ buf + max_size - 1) abort(-10, "entry_␣too_␣long");
  *(q - 1) ← '\0';

```

This code is used in section 4*.

9* A bugfix. The program specification had a subtle bug: There are cases where α includes spaces that should be removed in the output.

These cases occur when a space occurs after an odd number of doublequote characters. Ergo, the following routine replaced a simpler original loop.

```

⟨Scan past  $\alpha$  9*⟩ ≡
{
  int toggle ← 0;
  for ( $p \leftarrow buf + 2; (*p \neq ' \_ ' \vee toggle) \wedge *p; p++$ )
    if ( $*p \equiv ' \" ' ')$  toggle  $\oplus = 1$ ;
}

```

This code is used in section 6*.

10* A corresponding change to the copying loop is also needed.

```

⟨Copy the buffer to  $x$ -entry 10*⟩ ≡
{
  int toggle ← 0;
  for ( $p \leftarrow buf + 2, q \leftarrow x$ -entry;  $(*p \neq ' \_ ' \vee toggle) \wedge *p; p++$ ) {
    if ( $*p \equiv ' \" ' ')$  toggle  $\oplus = 1$ ;
    if ( $*p \neq ' \_ ' ')$   $*q++ \leftarrow *p$ ;
  }
  for (;  $*p; p++$ )  $*q++ \leftarrow *p$ ;
}

```

This code is used in section 6*.

11* Index.
